- Skipping data from a file that is not a regular disk file (for example, data from an internet socket).

## Syntax

SKIP_LUN, *FromUnit*, [, *Num*] [, /EOF] [, /LINES]
[, /TRANSFER_COUNT=*variable*]

## Arguments

### FromUnit

An integer that specifies the file unit for the file in which the file pointer is to be moved. Data in *FromUnit* is skipped, starting at the current position of the file pointer. The file pointer is advanced as data is read and skipped. The file specified by *FromUnit* must be open, and must not have been opened with the RAWIO keyword to OPEN.

### Num

The amount of data to skip. This value is specified in bytes, unless the LINES keyword is specified, in which case it is taken to be the number of text lines. If *Num* is not specified, SKIP_LUN acts as if the EOF keyword has been set, and skips all data in *FromUnit* (the source file) from the current position of the file pointer to the end of the file.

If *Num* is specified and the source file comes to end of file before the specified amount of data is skipped, SKIP_LUN issues an end-of-file error. The EOF keyword alters this behavior.

# Keywords

## EOF

Set this keyword to ignore the value given by *Num* (if present) and instead skip all data from the current position of the file pointer in *FromUnit* and the end of the file.

**Note**

If EOF is set, no end-of-file error is issued even if the amount of data skipped does not match the amount specified by *Num*. The TRANSFER_COUNT keyword can be used with EOF to determine how much data was skipped.

## LINES

Set this keyword to indicate that the *Num* argument specifies the number of lines of text to be skipped. By default, the *Num* argument specifies the number of bytes of data to skip.

## TRANSFER_COUNT

Set this keyword equal to a named variable that will contain the amount of data skipped. If LINES is specified, this value is the number of lines of text. Otherwise, it is the number of bytes. TRANSFER_COUNT is primarily useful in conjunction with the EOF keyword. If EOF is not specified, TRANSFER_COUNT will be the same as the value specified for *Num*.

# Examples

Skip the next 8 lines of text from a file:

```
SKIP_LUN, FromUnit, 8, /LINES
```

Skip the remainder of the data in a file, and use the TRANSFER_COUNT keyword to determine how much data was skipped:

```
SKIP_LUN, FromUnit, /EOF, TRANSFER_COUNT=n
```

Skip the remainder of the text lines in a file, and use the TRANSFER_COUNT keyword to determine how many lines were skipped:

```
SKIP_LUN, FromUnit, /EOF, /LINES, TRANSFER_COUNT=n
```

## Version History

Introduced: 5.6

# SLICER3

The IDL SLICER3 is a widget-based application to visualize three-dimensional datasets. This program supersedes the SLICER program.

This routine is written in the IDL language. Its source code can be found in the file `slicer3.pro` in the `lib` subdirectory of the IDL distribution.

**Note**

See "The SLICER3 Graphical User Interface" on page 1812 for details on working with volumetric data within this application.

## Syntax

SLICER3 [, *hData3D*] [, DATA_NAMES=*string/string_array*] [, /DETACH] [, GROUP=*widget_id*] [, /MODAL]

## Arguments

### hData3D

A pointer to a three-dimensional data array, or an array of pointers to multiple three-dimensional arrays. If multiple arrays are specified, they all must have the same X, Y, and Z dimensions. If *hData3D* is not specified, SLICER3 creates a 2 x 2 x 2 array of byte data using the IDL BYTARR function. You can also load data interactively via the File menu of the SLICER3 application (see "Examples" on page 1827 for details).

**Note**

If data are loaded in this fashion, any data passed to SLICER3 via a pointer (or pointers) is deleted, and the pointers become invalid.

## Keywords

### DATA_NAMES

Set this keyword equal to a string array of names for the data. The names appear on the droplist widget for the current data. If the number of elements of DATA_NAMES is less than the number of elements in *hData3D* then default names will be generated for the unnamed data.

## DETACH

Set this keyword to place the drawing area in a window that is detached from the SLICER3 control panel. The drawing area can only be detached if SLICER3 is not run as a modal application.

## GROUP

Set this keyword equal to the Widget ID of an existing widget that serves as the "group leader" for the SLICER3 graphical user interface. When a group leader is destroyed, all widgets in the group are also destroyed. If SLICER3 is started from a widget application, then GROUP should *always* be specified.

## MODAL

Set this keyword to block user interaction with all other widgets (and block the command line) until the SLICER3 exits. If SLICER3 is started from some other widget-based application, then it is usually advisable to run SLICER3 with the MODAL keyword set.

**Note**

SLICER3 modifies the current color table, as well as various elements of the plotting system (i.e., the "!X", "!Y", "!Z", and "!P" system variables). If the MODAL keyword is set (recommended), then SLICER3 will, upon exit, restore these system variables (and the color tables) to the values they had when SLICER3 was started.

# The SLICER3 Graphical User Interface

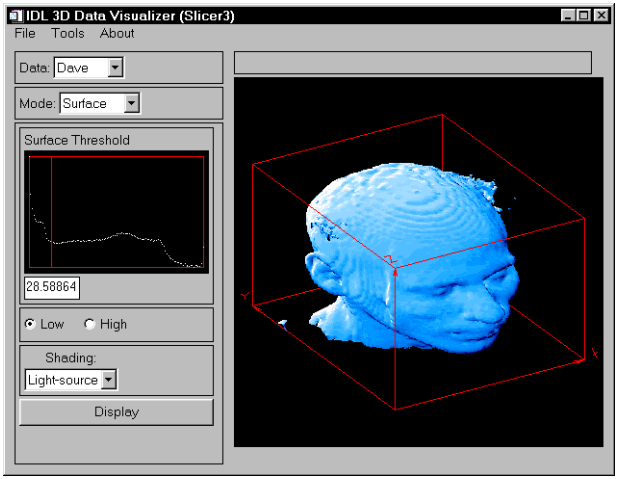

*Figure 20: SLICER3 Graphical User Interface*

The following options are available via SLICER3's graphical user interface.

## File Menu

### Load

Select this menu option to choose a file containing a 3-D array (or arrays) to load into SLICER3. The file must have been written in the format specified in the following table. For each data array in the file, the following values must be included. Note that the first six values are returned by the IDL SIZE function; see "Examples" on page 1827 for an example of how to create a data file suitable for SLICER3 with just a few IDL commands.

| Data item | Data Type | Number of Bytes |
|---|---|---|
| Number of dimension in array.<br>**Note -** This is always 3 for valid SLICER3 data.) | long | 4 |

*Table 89: SLICER3 Data File Structure*

| Data item | Data Type | Number of Bytes |
|---|---|---|
| Size of first dimension. | long | 4 |
| Size of second dimension. | long | 4 |
| Size of third dimension. | long | 4 |
| Data type (Must be type 1 through 5. See “SIZE” on page 1800 for a list of data types.) | long | 4 |
| Total number of elements (dimX, dimY, dimZ). | long | 4 |
| Number of characters in data name. (See “STRLEN” on page 1905 for the easiest way to determine this number.) | long | 4 |
| Data name | byte | strlen() |
| 3-D data array. | varies | varies |

*Table 89: SLICER3 Data File Structure (Continued)*

If multiple arrays are present in the file, they must all have the same dimensions.

**Note**

Files saved by the “Save Subset” operation (see below) are suitable for input via the “Load” operation.

Data files that are moved from one platform to another may not load as expected, due to byte ordering differences. See the BYTEORDER and SWAP_ENDIAN for details.

### Save/Save Subset

SLICER3 must be in BLOCK mode to for this option to be available.

Select this menu option to save a subset of the 3-D data enclosed in the current block to the specified file. Subsets saved in this fashion are suitable for loading via the “Load” menu option. If multiple 3-D arrays are available when this option is selected, multiple subsets are saved to the file.

### Save/Save Tiff Image

Select this menu option to save the contents of the current SLICER3 image window as a TIFF image in the specified file. When running in 8-bit mode, a “Class P” palette color TIFF file is created. In 24-bit mode, a “Class R” (interleaved by image) TIFF file is created.

### Quit

Select this menu option to exit SLICER3.

## Tools Menu

### Erase

Select this menu option to erase the display window and delete all the objects in the display list.

### Delete/...

As graphical objects are created, they are added to the display list. Select this menu option to delete a specific object from the list. When an object is deleted, the screen is redrawn with the remaining objects.

### Colors/Reset Colors

Select this menu option to restore the original color scheme.

### Colors/Differential Shading

Use this menu option to change the percentage of differential shading applied to the X, Y, and Z slices.

### Colors/Slice/Block

Use this menu option to launch the XLOADCT application to modify the colors used for slices and blocks

### Colors/Surface

Use this menu option to launch the XLOADCT application to modify the colors used for isosurfaces.

### Colors/Projection

Use this menu option to launch the XLOADCT application to modify the colors used for projections.

**Note**

On some platforms, the selected colors may not become visible until after you exit the “XLOADCT” application.

### Options

Select this menu option to display a panel that allows you to set:

- The axis visibility.
- The wire-frame cube visibility.
- The display window size.

## Main Draw Window

Operations available in the Main Draw Window are dependent on the mode selected in the Mode pulldown menu. In general, when coordinate input is required from the user, it is performed by clicking a mouse button on the “surface” of the wire-frame cube that surrounds the data. This 3-D location is then used as the basis for whatever input is needed. In most cases, the “front” side of the cube is used. In a few cases, the coordinate input is on the “back” side of the cube.

## Data Pulldown Menu

If multiple datasets are currently available in SLICER3, this menu allows you to select which data will be displayed in the Main Draw Window. Slices, blocks, iso-surfaces, etc. are created from the currently selected data. If only one dataset is loaded, this menu is inactive.

## Mode Pulldown Menu

This menu is used to select the current mode of operation.

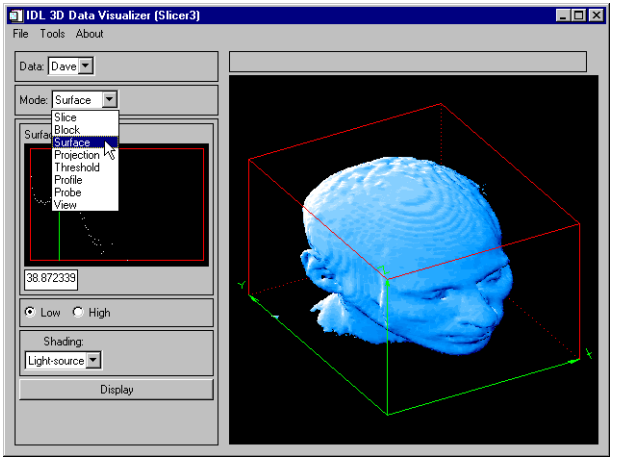

*Figure 21: Mode Pulldown Menu*

### Slice Mode

To display a slice, click and drag the left mouse button on the wire-frame cube. When the button is released, a slice through the data will be drawn at that location.

## Draw Radio Button

When in Draw mode, new slices will be merged into the current Z-buffer contents.

## Expose Radio Button

When in Expose mode, new slices will be drawn in front of everything else.

## Orthogonal Radio Button

When in Orthogonal mode, use the left mouse button in the main draw window to position and draw an orthogonal slicing plane. Clicking the right mouse button in the main draw window (or any mouse button in the small window) will toggle the slicing plane orientation.

## X/Y/Z Radio Buttons

- X: This sets the orthogonal slicing plane orientation to be perpendicular to the X axis.
- Y: This sets the orthogonal slicing plane orientation to be perpendicular to the Y axis.
- Z: This sets the orthogonal slicing plane orientation to be perpendicular to the Z axis.

## Oblique Radio Button

Clicking any mouse button in the small window will reset the oblique slicing plane to its default orientation.

## Normal Radio Button

When in this mode, click and drag the left mouse button in the big window to set the surface normal for the oblique slicing plane.

## Center Radio Button

When in this mode, click and drag the left mouse button in the big window to set the center point for the surface normal.

## Display Button

Clicking this button will cause an oblique slicing plane to be drawn.

## Block Mode

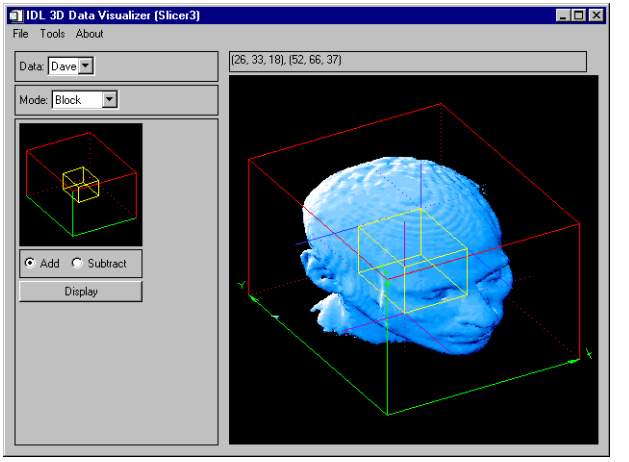

*Figure 22: Block Mode*

When in Block mode, use the left mouse button in the main draw window to set the location for the “purple” corner of the block. Use the right mouse button to locate the opposite “blue” corner of the block. When in Block mode, the “Save Subset” operation under the main “File” menu is available.

### Add

When in this mode, the block will be “added” to the current Z-buffer contents.

### Subtract

When in this mode, the block will be “subtracted” from the current Z-buffer contents. Subtract mode is only effective when the block intersects some other object in the display (such as an iso-surface).

### Display Button

Clicking this button will cause the block to be drawn.

## Surface Mode

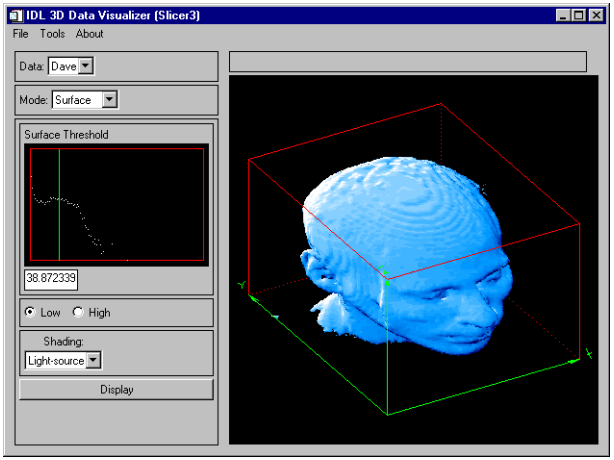

*Figure 23: Surface Mode*

An iso-surface is like a contour line on a contour map. On one side of the line, the elevation is higher than the contour level, and on the other side of the line, the elevation is lower than the contour level. An iso-surface, however, is a 3-D surface that passes through the data such that the data values on one side of the surface are higher than the threshold value, and on the other side of the surface, the data values are lower than the threshold value.

When in Surface mode, a logarithmic histogram plot of the data is displayed in the small draw window. Click and drag a mouse button on this plot to set the iso-surface threshold value. This value is also shown in the text widget below the plot. The threshold value may also be set by typing a new value in this text widget. The histogram plot is affected by the current threshold settings. (See Threshold mode, below).

### Low

Selecting this mode will cause the iso-surface polygon facing to face towards the lower data values. Usually, this is the mode to use when the iso-surface is desired to surround high data values.

### High

Selecting this mode will cause the iso-surface polygon facing to face towards the higher data values. Usually, this is the mode to use when the iso-surface is desired to surround low data values.

### Shading pulldown menu

Iso-surfaces are normally rendered with light-source shading. If multiple datasets are currently loaded, then this menu allows the selection of a different 3-D array for the source of the iso-surface shading values. If only one dataset is currently loaded, then this menu is inactive.

### Display Button

Clicking this button will cause the iso-surface to be created and drawn. Iso-surfaces often consist of tens of thousands of polygons, and can sometimes take considerable time to create and render.

## Projection Mode

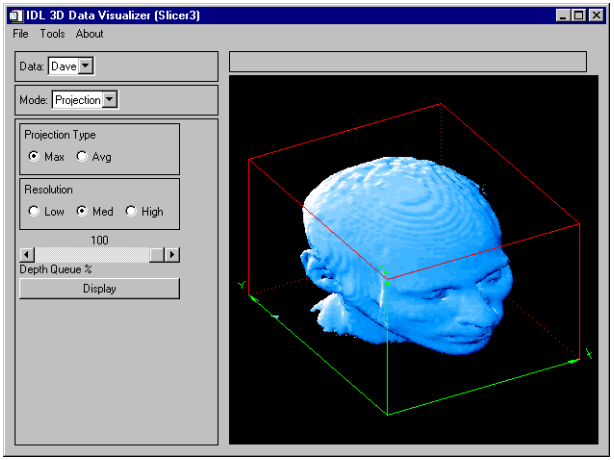

*Figure 24: Projection Mode*

A “voxel” projection of a 3-D array is the projection of the data values within that array onto a viewing plane. This is similar to taking an X-ray image of a 3-D object.

### Max

Select this mode for a Maximum intensity projection.

### Avg

Select this mode for an Average intensity projection.

### Low

Select this mode for a Low resolution projection.

### Med

Select this mode for a Medium resolution projection.

### High

Select this mode for a High resolution projection.

### Depth Queue % Slider

Use the slider to set the depth queue percent. A value of 50, for example, indicates that the farthest part of the projection will be 50% as bright as the closest part of the projection.

### Display Button

Clicking this button will cause the projection to be calculated and drawn. Projections can sometimes take considerable time to display. Higher resolution projections take more computation time.

## Threshold Mode

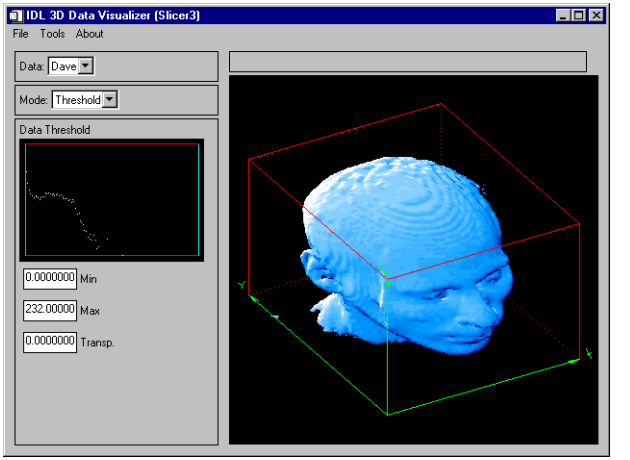

*Figure 25: Threshold Mode*

When in Threshold mode, a logarithmic histogram plot of the data is displayed in the small draw window. Click and drag the left mouse button on this plot to set the minimum and maximum threshold values. To expand a narrow range of data values into the full range of available colors, set the threshold range before displaying slices, blocks, or projections. The threshold settings also affect the histogram plot in "Surface" mode. The minimum and maximum threshold values are also shown in the text widgets below the histogram plot.

Click and drag the right mouse button on the histogram plot to set the transparency threshold. Portions of any slice, block, or projection that are less than the transparency value are not drawn (clear). Iso-surfaces are not affected by the transparency threshold. The transparency threshold value is also shown in a text widget below the histogram plot.

### Min

In this text widget, a minimum threshold value can be entered.

### Max

In this text widget, a maximum threshold value can be entered.

### Transp.

In this text widget, a transparency threshold value can be entered.

## Profile Mode

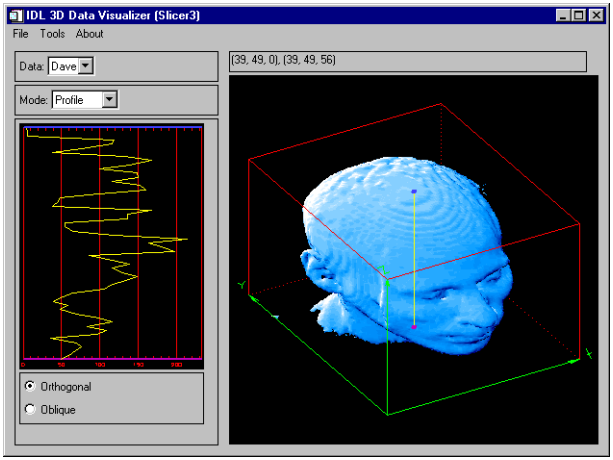

*Figure 26: Profile Mode*

In Profile mode, a plot is displayed showing the data values along a line. This line is also shown superimposed on the data in the main draw window. The bottom of the plot corresponds to the “purple” end of the line, and the top of the plot corresponds to the “blue” end of the line.

### Orthogonal

Click and drag the left mouse button to position the profile line, based upon a point on the “front” faces of the wire-frame cube. Click and drag the right mouse button to position the profile line, based upon a point on the “back” faces of the wire-frame cube. As the profile line is moved, The profile plot is dynamically updated.

### Oblique

Click and drag the left mouse button to position the “purple” end of the profile line on one of the “front” faces of the wire-frame cube. Click and drag the right mouse button to position the “blue” end of the profile line on one of the “back” faces of the wire-frame cube. As the profile line is moved, The profile plot is dynamically updated.

## Probe Mode

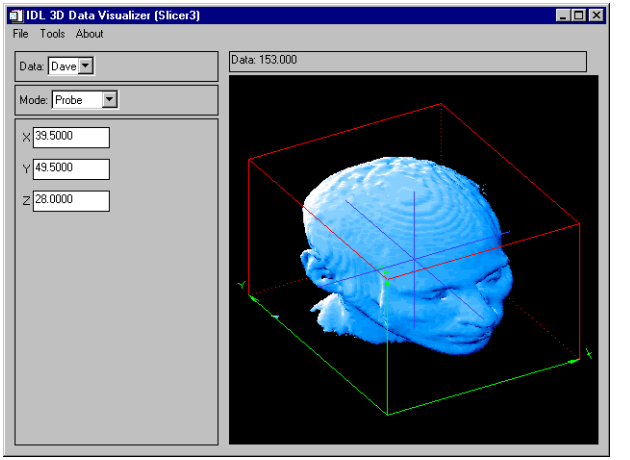

*Figure 27: Probe Mode*

In Probe mode, click and drag a mouse button over an object in the main draw window. The actual X-Y-Z location within the data volume is displayed in the three text widgets. Also, the data value at that 3-D location is displayed in the status window, above the main draw window. If the cursor is inside the wire-frame cube, but not on any object, then the status window displays “No data value”, and the three text widgets are empty. If the cursor is outside the wire-frame cube, then the status window and text widgets are empty.

**X**

Use this text widget to enter the X coordinate for the probe.

**Y**

Use this text widget to enter the Y coordinate for the probe.

**Z**

Use this text widget to enter the Z coordinate for the probe.

## View Mode

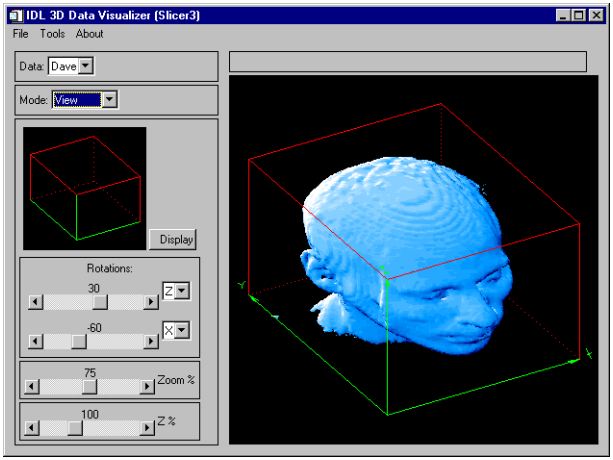

*Figure 28: View Mode*

In view mode, a small window shows the orientation of the data cube in the current view. As view parameters are changed, this window is dynamically updated. The main draw window is then updated when the user clicks on “Display”, or exits View mode.

### Display

Clicking on this button will cause the objects in the main view window to be drawn in the new view. If any view parameters have been changed since the last time the main view was updated, the main view will be automatically redrawn when the user exits View mode.

### 1st Rotation

Use this slider to set the angle of the first view rotation (in degrees). The droplist widget adjacent to the slider indicates which axis this rotation is about.

### 2nd Rotation

Use this slider to set the angle of the second view rotation (in degrees). The droplist widget adjacent to the slider indicates which axis this rotation is about.

### Zoom % Slider

Use this slider to set the zoom factor percent. Depending upon the view rotations, SLICER3 may override this setting to ensure that all eight corners of the data cube are within the window.

### Z % Slider

Use this slider to set a scale factor for the Z axis (to compensate for the data's aspect ratio).

## Operational Details

The SLICER3 procedure has the following side effects:

- SLICER3 sets the position for the light source and enables back-facing polygons to be drawn (see the IDL "SET_SHADING" command).
- SLICER3 overwrites the existing contents of the Z-buffer. Upon exiting SLICER3, the Z-buffer contents are the same as what was last displayed by SLICER3.
- On 24-bit displays, SLICER3 sets the device to non-decomposed color mode (DEVICE, DECOMPOSED=0).
- SLICER3 breaks the color table into 6 "bands", based upon the number of available colors (where `max_color=!D.N_COLORS` on 8-bit displays, and `max_color=256` on 24-bit displays and `nColor = (max_color - 9) / 5`):

| Band Start index | Band End index | Used For |
|---|---|---|
| 0 | nColor-1 | X Slices. |
| nColor | (2*nColor)-1 | Y Slices. |
| 2*nColor | (3*nColor)-1 | Z Slices. |
| 3*nColor | (4*nColor)-1 | Iso-surfaces |
| 4*nColor | (5*nColor)-1 | Projections |

*Table 90: SLICER3 Band Start/End*

Annotation colors are the last “band”, and they are set up as shown in the table:

| Color index | Color |
|---|---|
| max_color - 1 | White |
| max_color - 2 | Yellow |
| max_color - 3 | Cyan |
| max_color - 4 | Purple |
| max_color - 5 | Red |
| max_color - 6 | Green |
| max_color - 7 | Blue |
| max_color - 8 | Black |

*Table 91: SLICER3 Color Bands*

On 24-bit displays, you can often improve performance by running SLICER3 in 8-bit mode. This can be accomplished (on some platforms) by entering the following command at the start of the IDL session (before any windows are created):

```
Device, Pseudo_Color=8
```

# Examples

The following IDL commands open a data file from the IDL distribution and load it into SLICER3:

```
; Choose a data file:
file=FILEPATH('head.dat', SUBDIR=['examples', 'data'])

; Open the data file:
OPENR, UNIT, file, /GET_LUN

; Create an array to hold the data:
data = BYTARR(80, 100, 57, /NOZERO)

; Read the data into the array:
READU, UNIT, data

; Close the data file:
CLOSE, UNIT
```

```
; Create a pointer to the data array:
hData = PTR_NEW(data, /NO_COPY)

; Load the data into SLICER3:
SLICER3, hdata, DATA_NAMES='Dave'
```

**Note**

If data are loaded via the File menu after SLICER3 is launched with a pointer argument (as shown above), the pointer becomes invalid. You can use an IDL statement like the following to “clean up” after calling SLICER3 in this fashion:

```
if PTR_VALID(hdata) then PTR_FREE, hdata
```

Because we did not launch SLICER3 with the MODAL keyword, the last contents of the main draw window still reside in IDL’s Z-buffer. To retrieve this image after exiting SLICER3, use the following IDL statements:

```
; Save the current graphics device:
current_device = !D.Name

; Change to the Z-buffer device:
SET_PLOT, 'Z'

; Read the image from the Z-buffer:
image_buffer = TVRD()

; Return to the original graphics device:
SET_PLOT, current_device

; Display the image:
TV, image_buffer
```

The following IDL commands manually create a data save file suitable for dynamic loading into SLICER3. Note that if you load data into SLICER3 as shown above, you can also create save files by switching to BLOCK mode and using the Save Subset menu option.

```
; Store some 3-D data in a variable called data_1:
data_1 = INDGEN(20,30,40)

; Store some 3-D data in a variable called data_2:
data_2 = FINDGEN(20,30,40)

; Define the names for the datasets. Their names will appear in the
; "Data" pulldown menu in SLICER3:
data_1_name ='Test Data 1'
data_2_name ='Data 2'
```

```
; Select a data file name:
dataFile = PICKFILE()

; Write the file:
GET_LUN, lun
OPENW, lun, dataFile
WRITEU, lun, SIZE(data_1)
WRITEU, lun, STRLEN(data_1_name)
WRITEU, lun, BYTE(data_1_name)
WRITEU, lun, data_1
WRITEU, lun, SIZE(data_2)
WRITEU, lun, STRLEN(data_2_name)
WRITEU, lun, BYTE(data_2_name)
WRITEU, lun, data_2
CLOSE, lun
FREE_LUN, lun
```

GRID3, EXTRACT_SLICE, IVOLUME, SHADE_VOLUME, XVOLUME

# SLIDE_IMAGE

The SLIDE_IMAGE procedure creates a scrolling graphics window for examining large images. By default, 2 draw widgets are used. The draw widget on the left shows a reduced version of the complete image, while the draw widget on the right displays the actual image with scrollbars that allow sliding the visible window.

This routine is written in the IDL language. Its source code can be found in the file `slide_image.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

SLIDE_IMAGE [, *Image*] [, /BLOCK] [, CONGRID=0]
[, FULL_WINDOW=*variable*] [, GROUP=*widget_id*] [, /ORDER] [, /REGISTER]
[, RETAIN={0 | 1 | 2}] [, SLIDE_WINDOW=*variable*] [, SHOW_FULL=0]
[, TITLE=*string*] [, TOP_ID=*variable*] [, XSIZE=*width*] [, XVISIBLE=*width*]
[, YSIZE=*height*] [, YVISIBLE=*height*]

## Arguments

### Image

A 2-D image array to be displayed. If this argument is not specified, no image is displayed. The FULL_WINDOW and SCROLL_WINDOW keywords can be used to obtain the window numbers of the two draw widgets so they can be drawn into at a later time.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have SLIDE_IMAGE block, any earlier calls to XMANAGER must have been called

with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

## CONGRID

Normally, the image is processed with the CONGRID procedure before it is written to the fully visible window on the left. Specifying CONGIRD=0 will force the image to be drawn as is.

## FULL_WINDOW

Set this keyword to a named variable that will contain the IDL window number of the fully visible window. This window number can be used with the WSET procedure to draw to the scrolling window at a later point.

## GROUP

Set this keyword to the widget ID of the widget that calls SLIDE_IMAGE. If set, the death of the caller results in the death of SLIDE_IMAGE.

## ORDER

This keyword is passed directly to the TV procedure to control the order in which the images are drawn. Usually, images are drawn from the bottom up. Set this keyword to a non-zero value to draw images from the top down.

## REGISTER

Set this keyword to create a “Done” button for SLIDE_IMAGE and register the widgets with the XMANAGER procedure.

The basic widgets used in this procedure do not generate widget events, so it is not necessary to process events in an event loop. The default is therefore to simply create the widgets and return. Hence, when REGISTER is not set, SLIDE_IMAGE can be displayed and the user can still type commands at the IDL command prompt.

## RETAIN

This keyword is passed directly to the WIDGET_DRAW function. RETAIN specifies how backing store should be handled for the window. Valid values are:

- 0 — Specifies no backing store. In this case, it is recommended that the REGISTER keyword be set so that expose and scroll events are handled.

- 1 — Requests that the server or window system provide backing store. This is the default if RETAIN is not specified.
- 2 — Specifies that IDL provide backing store directly.

See “Backing Store” on page 3824 for details.

## SLIDE_WINDOW

Set this keyword to a named variable that will contain the IDL window number of the sliding window. This window number can be used with the WSET procedure to draw to the scrolling window at a later time.

## SHOW_FULL

Set this keyword to zero to show the entire image at full resolution in one scrolling graphics window. By default, SHOW_FULL is set, displaying two draw widgets.

**Note**

On Windows platforms only, using TVRD to return the array size of the displayed image will cause the returned array to be off by the size of the frame (one pixel per side). To return the dimensions of the original image, you must modify the `slide_image.pro` library routine so that the FRAME keyword is not used with SHOW_FULL.

## TITLE

Set this keyword to the title to be used for the SLIDE_IMAGE widget. If this keyword is not specified, “Slide Image” is used.

## TOP_ID

Set this keyword to a named variable that will contain the top widget ID of the SLIDE_IMAGE hierarchy. This ID can be used to kill the hierarchy as shown below:

```
SLIDE_IMAGE, TOP_ID=base, ...
WIDGET_CONTROL, /DESTROY, base
```

## XSIZE

Set this keyword to the maximum width of the image that can be displayed by the scrolling window. This keyword should not be confused with the visible size of the image, controlled by the XVISIBLE keyword. If XSIZE is not specified, the width of *Image* is used. If *Image* is not specified, 256 is used.

### XVISIBLE

Set this keyword to the width of the viewport on the scrolling window. If this keyword is not specified, 256 is used.

### YSIZE

Set this keyword to the maximum height of the image that can be displayed by the scrolling window. This keyword should not be confused with the visible size of the image, controlled by the YVISIBLE keyword. If YSIZE is not present the height of *Image* is used. If *Image* is not specified, 256 is used.

### YVISIBLE

Set this keyword to the height of the viewport on the scrolling window. If this keyword is not present, 256 is used.

## Examples

Open an image from the IDL distribution and load it into SLIDE_IMAGE:

```
; Create a variable to hold the image:
image = BYTARR(768,512)

OPENR, unit, FILEPATH('nyny.dat', SUBDIR=['examples','data']),
/GET_LUN
READU, unit, image
CLOSE, unit

; Scale the image into byte range of the display:
image = BYTSCL(image)

; Display the image:
SLIDE_IMAGE, image
```

# SMOOTH

The SMOOTH function returns a copy of *Array* smoothed with a boxcar average of the specified width. The result has the same type and dimensions as *Array*. The algorithm used by SMOOTH is:

$$R_i = \begin{cases} \frac{1}{w}\sum_{j=0}^{w-1} A_{i+j-w/2}, & i = \frac{(w-1)}{2}, \ldots, N - \frac{(w+1)}{2} \\ A_i, \text{ otherwise} & \end{cases}$$

where *N* is the number of elements in A.

## Syntax

*Result* = SMOOTH( *Array*, *Width* [, /EDGE_TRUNCATE] [, MISSING=*value*] [, /NAN] )

## Return Value

Returns the smoothed array, which has the same dimensions as the input array.

## Arguments

### Array

The array to be smoothed. *Array* can have any number of dimensions.

### Width

The width of the smoothing window. *Width* can either be a scalar or a vector with length equal to the number of dimensions of *Array*. If *Width* is a scalar then the same width is applied for each dimension that has length greater than 1 (dimensions of length 1 are skipped). If *Width* is a vector, then each element of *Width* is used to specify the smoothing width for each dimension of *Array*. Values for *Width* must be smaller than the corresponding *Array* dimension. If a *Width* value is even, then *Width*+1 will be used instead. The value of *Width* does not affect the running time of SMOOTH to a great extent.

**Note**

A Width value of zero or 1 implies no smoothing. However, if the NAN keyword is set, then any NaN values within the Array will be treated as missing data and will be replaced.

**Tip**

For a multi-dimensional array, set widths to 1 within the Width vector for dimensions that you don't want smoothed.

# Keywords

## EDGE_TRUNCATE

Set this keyword to apply the smoothing function to all points. If the neighborhood around a point includes a point outside the array, the nearest edge point is used to compute the smoothed result. If EDGE_TRUNCATE is not set, the end points are copied from the original array to the result with no smoothing.

For example, when smoothing an *n*-element vector with a three point wide smoothing window, the first point of the result $R_0$ is equal to $A_0$ if EDGE_TRUNCATE is not set, but is equal to $(A_0+A_0+A_1)/3$ if the keyword is set. In the same manner, point $R_{n-1}$ is set to $A_{n-1}$ if EDGE_TRUNCATE is not set, or to $(A_{n-2}+A_{n-1}+A_{n-1})/3$ if it is.

Points not within a distance of *Width*/2 from an edge are not affected by this keyword.

**Note**

Normally, two-dimensional floating-point arrays are smoothed in one pass. If both the EDGE_TRUNCATE and NAN keywords are specified for a two-dimensional array, the result is obtained in two passes, one for each dimension. Therefore, the results may differ slightly when both the EDGE_TRUNCATE and NAN keywords are set.

## MISSING

The value to return for elements that contain no valid points within the kernel. The default is the IEEE floating-point value NaN. This keyword is only used if the NAN keyword is set.

## NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point value NaN in the input data. (See “Special Floating-Point Values” in Chapter 18

of the *Building IDL Applications* manual for more information on IEEE floating-point values.) Elements with the value NaN are treated as missing data, and are ignored when computing the smooth value for neighboring elements. In the *Result*, missing elements are replaced by the smoothed value of all other valid points within the smoothing window. If all points within the window are missing, then the result at that point is given by the MISSING keyword.

**Note**

SMOOTH should never be called without the NAN keyword if the input array may possibly contain NaN values.

## Examples

Create and display a simple image by entering:

```
WINDOW, XSIZE=800, YSIZE=400
D = SIN(DIST(256)/3)
TVSCL, D
```

Now display the same dataset smoothed with a width of 9 in each dimension by entering:

```
TVSCL, SMOOTH(D, 9), 256, 0
```

Now smooth only in the vertical direction with a width of 15:

```
TVSCL, SMOOTH(D, [1, 15]), 512, 0
```

# SOBEL

The SOBEL function returns an approximation to the Sobel edge enhancement operator for images,

$$G_{jk} = |G_x| + |G_y|$$

$$G_Y = F_{j-1,\,k-1} + 2F_{j,\,k-1} + F_{j+1,\,k-1} - (F_{j-1,\,k+1} + 2F_{j,\,k+1} + F_{j+1,\,k+1})$$

$$G_X = F_{j+1,\,k+1} + 2F_{j+1,\,k} + F_{j+1,\,k-1} - (F_{j-1,\,k+1} + 2F_{j-1,\,k} + F_{j-1,\,k-1})$$

where (*j*, *k*) are the coordinates of each pixel $F_{jk}$ in the *Image*. This is equivalent to a convolution using the masks,

$$\text{X mask} = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix} \qquad \text{Y mask} = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix}$$

All of the edge points in the result are set to zero.

## Syntax

*Result* = SOBEL(*Image*)

## Return Value

SOBEL returns a two-dimensional array of the same size as *Image*. If *Image* is of type byte or integer then the result is of integer type, otherwise the result is of the same type as *Image*.

**Note**

To avoid overflow for integer types, the computation is done using the next larger signed type and the result is transformed back to the correct type. Values larger than the maximum for that integer type are truncated. For example, for integers the

function is computed using type long, and on output, values larger than 32767 are set equal to 32767.

## Arguments

### Image

The two-dimensional array containing the image to which edge enhancement is applied.

## Keywords

None.

## Examples

If the variable `myimage` contains a two-dimensional image array, a Sobel sharpened version of `myimage` can be displayed with the command:

```
TVSCL, SOBEL(myimage)
```

## Version History

ROBERTS

# SOCKET

The SOCKET procedure, supported on UNIX and Microsoft Windows platforms, opens a client-side TCP/IP Internet socket as an IDL file unit. Such files can be used in the standard manner with any of IDL's Input/Output routines.

**Tip**

RSI recommends that you don't use the EOF procedure as a way to check to see if a socket is empty. It is recommended that you structure your communication across the socket so that using EOF is not necessary to know when the communication is complete.

## Syntax

SOCKET, *Unit*, *Host*, *Port* [, CONNECT_TIMEOUT=*value*] [, ERROR=*variable*] [, /GET_LUN] [, /RAWIO] [, READ_TIMEOUT=*value*] [, /SWAP_ENDIAN] [, /SWAP_IF_BIG_ENDIAN] [, /SWAP_IF_LITTLE_ENDIAN] [, WIDTH=*value*] [, WRITE_TIMEOUT=*value*]

**UNIX-Only Keywords:** [, /STDIO]

## Arguments

### Unit

The unit number to associate with the opened socket.

### Host

The name of the host to which the socket is connected. This can be either a standard Internet host name (e.g. `ftp.RSInc.com`) or a dot-separated numeric address (e.g. `192.5.156.21`).

### Port

The port to which the socket is connected on the remote machine. If this is a well-known port (as contained in the `/etc/services` file on a UNIX host), then you can specify its name (e.g. daytime); otherwise, specify a number.

# Keywords

## CONNECT_TIMEOUT

Set this keyword to the number of seconds to wait before giving up and issuing an error to shorten the connect timeout from the system-supplied default. Most experts recommend that you not specify an explicit timeout, and instead use your operating system defaults.

**Note**

Although you can use CONNECT_TIMEOUT to shorten the timeout, you cannot increase it past the system-supplied default.

## ERROR

A named variable in which to place the error status. If an error occurs in the attempt to open File, IDL normally takes the error handling action defined by the ON_ERROR and/or ON_IOERROR procedures. SOCKET always returns to the caller without generating an error message when ERROR is present. A nonzero error status indicates that an error occurred. The error message can then be found in the system variable !ERROR_STATE.MSG.

## GET_LUN

Set this keyword to use the GET_LUN procedure to set the value of *Unit* before the file is opened. Instead of using the two statements:

```
GET_LUN, Unit
OPENR, Unit, 'data.dat'
```

you can use the single statement:

```
OPENR, Unit, 'data.dat', /GET LUN
```

## RAWIO

Set this keyword to disable all use of the standard operating system I/O for the file, in favor of direct calls to the operating system. This allows direct access to devices, such as tape drives, that are difficult or impossible to use effectively through the standard I/O. Using this keyword has the following implications:

- No formatted or associated (ASSOC) I/O is allowed on the file. Only READU and WRITEU are allowed.

- Normally, attempting to read more data than is available from a file causes the unfilled space to be set to zero and an error to be issued. This does not happen with files opened with RAWIO. When using RAWIO, the programmer must check the transfer count, either via the TRANSFER_COUNT keywords to READU and WRITEU, or the FSTAT function.
- The EOF and POINT_LUN functions cannot be used with a file opened with RAWIO.
- Each call to READU or WRITEU maps directly to UNIX read(2) and write(2) system calls. The programmer must read the UNIX system documentation for these calls and documentation on the target device to determine if there are any special rules for I/O to that device. For example, the size of data that can be transferred to many cartridge tape drives is often forced to be a multiple of 512 bytes.

## READ_TIMEOUT

Set this keyword to the number of seconds to wait for data to arrive before giving up and issuing an error. By default, IDL blocks indefinitely until the data arrives. Typically, this option is unnecessary on a local network, but it is useful with networks that are slow or unreliable.

## STDIO (UNIX Only)

Under UNIX, forces the file to be opened via the standard C I/O library (stdio) rather than any other more native OS API that might usually be used. This is primarily of interest to those who intend to access the file from external code, and is not necessary for most uses.

**Note**

Under Windows, the STDIO feature is not possible. Requesting it causes IDL to throw an error.

## SWAP_ENDIAN

Set this keyword to swap byte ordering for multi-byte data when performing binary I/O on the specified file. This is useful when accessing files also used by another system with byte ordering different than that of the current host.

### SWAP_IF_BIG_ENDIAN

Setting this keyword is equivalent to setting SWAP_ENDIAN; it only takes effect if the current system has big endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

### SWAP_IF_LITTLE_ENDIAN

Setting this keyword is equivalent to setting SWAP_ENDIAN; it only takes effect if the current system has little endian byte ordering. This keyword does not refer to the byte ordering of the input data, but to the computer hardware.

### WIDTH

The desired output width. When using the defaults for formatted output, IDL uses the following rules to determine where to break lines:

- If the output file is a terminal, the terminal width is used.
- Otherwise, a default of 80 columns is used.

The WIDTH keyword allows the user to override this default.

### WRITE_TIMEOUT

Set this keyword to the number of seconds to wait to send data before giving up and issuing an error. By default, IDL blocks indefinitely until it is possible to send the data. Typically, this option is unnecessary on a local network, but it is useful with networks that are slow or unreliable.

## Examples

Most UNIX systems maintain a daytime server on the daytime port (port 13). These servers send a 1 line response when connected to, containing the current time of day.

```
; To obtain the current time from the host bullwinkle:
SOCKET, 1, 'bullwinkle','daytime'
date=''
READF, 1, date
CLOSE, 1
PRINT, date
```

IDL prints:

```
Wed Sep 15 17:20:27 1999
```

## Version History

Introduced: 5.3

SWAP_IF_BIG_ENDIAN, SWAP_IF_LITTLE_ENDIAN keywords added: 5.6

# SORT

The SORT function returns a vector of subscripts that allow access to the elements of *Array* in ascending order.

## Syntax

*Result* = SORT(*Array* [, /L64] )

## Return Value

The result is always a vector of integer type with the same number of elements as *Array.*

## Arguments

### Array

The array to be sorted. *Array* can be any basic type of vector or array. String arrays are sorted using the ASCII collating sequence. Complex arrays are sorted by their magnitude. Array values which are Not A Number (NaN) are moved to the end of the resulting array.

## Keywords

### L64

By default, the result of SORT is 32-bit integer when possible, and 64-bit integer if the number of elements being sorted requires it. Set L64 to force 64-bit integers to be returned in all cases.

**Note**

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit sort. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

## Examples

### Example 1

```
A = [4, 3, 7, 1, 2]
PRINT, 'SORT(A) = ', SORT(A)
```

```
; Display the elements of A in sorted order:
PRINT, 'Elements of A in sorted order: ', A[SORT(A)]

; Display the elements of A in descending order:
PRINT, 'Elements of A in descending order: ', A[REVERSE(SORT(A))]
```

IDL prints:

```
SORT(A) =   3   4   1   0   2
Elements of A in sorted order:   1   2   3   4   7
Elements of A in descending order:   7   4   3   2   1
```

SORT(A) returns “`3 4 1 0 2`” because:

A[3] < A[4] < A[1] < A[0] < A[2]

### Example 2

#### Sorting NaN Values

When sorting data including Not A Number (NaN) values, the NaN entries are moved to the end of the resulting array. For example:

```
values = [ 500, !VALUES.F_NAN, -500 ]
PRINT, SORT(values)
```

IDL prints:

```
2           0           1
```

REVERSE, UNIQ, WHERE

# SPAWN

The SPAWN procedure spawns a child process to execute a command or series of commands. The result of calling SPAWN depends on the platform on which it is being used:

- Under UNIX, the shell used (if any) is obtained from the SHELL environment variable. The NOSHELL keyword can be used to execute a command directly as a child process without starting a shell process.
- Under Windows, a Command Shell is opened. The NOSHELL keyword can be used to execute the specified command directly without starting an intermediate command interpreter shell.

**Note**

See "Using SPAWN Without a Shell Under UNIX" on page 1851 for notes on executing commands without using a shell process under UNIX. See "Execution Directory under Microsoft Windows" on page 1851 for a caution regarding Windows network paths.

If SPAWN is called without arguments, an interactive command interpreter process is started, in which you can enter one or more operating system commands.

By default, IDL waits for the child process started by SPAWN to finish before it continues. It is possible to have IDL instead continue execution in parallel with the child process. The syntax for this depends on the operating system on your system:

- Under UNIX, include an ampersand (&) at the end of your shell command.
- Under Windows, specify the NOWAIT keyword to SPAWN.

**Note**

For more information on using SPAWN, see the *External Development Guide*.

## Syntax

SPAWN [, *Command* [, *Result*] [, *ErrResult*] ]

**Keywords (all platforms):** [, COUNT=*variable*] [, EXIT_STATUS=*variable*] [ ,/NOSHELL] [, /NULL_STDIN] [, PID=*variable*] [, /STDERR]

**UNIX-Only Keywords:** [, /NOTTYRESET] [, /SH] [, /UNIT=*variable* {*Command* required, *Result* not allowed}]

**Windows-Only Keywords:** [, /HIDE] [, /LOG_OUTPUT] [, /NOWAIT]

# Arguments

## Command

A string containing the commands to be executed.

If *Command* is present, it must be specified as follows:

- On UNIX, *Command* is expected to be scalar unless used in conjunction with the NOSHELL keyword, in which case *Command* is expected to be a string array where each element is passed to the child process as a separate argument.
- On Windows, *Command* can be a scalar string or string array. If it is a string array, SPAWN glues together each element of the string array, with each element separated by whitespace.

If *Command* is not present, SPAWN starts an interactive command interpreter process, which you can use to enter one or more operating system commands. While you use the command interpreter process, IDL is suspended. Under Windows, an interactive command shell window is created for this purpose. UNIX spawn does not create a separate window, but simply runs on the user's current tty, using the default shell (as specified by the SHELL environment variable). The SH keyword can be used to force use of the Bourne shell (`/bin/sh`).

**Note**

Using SPAWN in this manner is equivalent to using the IDL $ command. The difference between these two is that $ can only be used interactively while SPAWN can be used interactively or in IDL programs

## Result

A named variable in which to place the output from the child process. Each line of output becomes a single array element. If *Result* is not present, the output from the child shell process goes to the standard output (usually the terminal).

## ErrResult

A named variable in which to place the error output (stderr) from the child process. Each line of output becomes a single array element. If *ErrResult* is not present, the error output from the child shell process goes to the standard error file.

**Note**

See the STDERR keyword for another error stream option.

# Keywords

## COUNT

If *Result* is present and this keyword is also specified, COUNT specifies a named variable into which the number of lines of output is placed. This value gives the number of elements placed into *Result*.

## EXIT_STATUS

Set this keyword to a named variable in which the exit status for the child process is returned. The meaning of this value is operating system dependent:

- Under UNIX, it is the value passed by the child to exit(2), and is analogous to the value returned by $? under most UNIX shells. If the UNIT keyword is used, this keyword always returns 0. In this case, use the EXIT_STATUS keyword to FREE_LUN or CLOSE to determine the final exit status of the process.
- Under Windows, it is the value returned by the Win32 GetExitCodeProcess() system function. If the NOWAIT keyword is set, EXIT_STATUS returns 0.

## HIDE (WINDOWS Only)

If HIDE is set, the command interpreter shell window is minimized to prevent the user from seeing it.

## LOG_OUTPUT (WINDOWS Only)

Normally, IDL starts a command interpreter shell, and output from the child process is displayed in the command interpreter's window. If LOG_OUTPUT is set, the command interpreter window is minimized (as with HIDE) and all output is diverted to the IDLDE log window. If the *Result* or *ErrResult* arguments are present, they take precedence over LOG_OUTPUT.

## NOSHELL

Set this keyword to specify that *Command* should execute directly as a child process without an intervening shell process.

- UNIX – When using the NOSHELL keyword under UNIX, you must specify *Command* as a string array in which the first element is the name of the command to execute and the following arguments are the arguments to be passed to the command. See "Using SPAWN Without a Shell Under UNIX" on page 1851 for notes on executing commands without using a shell process.
- Windows – Use this keyword to start the specified *Command* directly, without the use of an intervening command shell. This is useful for Windows programs that do not require a console, such as Notepad.

  Many common DOS commands (e.g. DIR) are not distinct programs, and are instead implemented as part of the command interpreter. Specifying NOSHELL with such commands results in the command not being found. In such cases, the HIDE keyword might be useful.

## NOTTYRESET (UNIX Only)

Some UNIX systems drop characters when the tty mode is switched between normal and raw modes. IDL switches between these modes when reading command input and when using the GET_KBRD function. On such systems, IDL avoids losing characters by delaying the switch back to normal mode until it is truly needed. This method has the benefit of avoiding the large number of mode changes that would otherwise be necessary. Routines that cause output to be sent to the standard output (e.g., I/O operations, user interaction and SPAWN) ensure that the tty is in its normal mode before performing their operations.

If the NOTTYRESET keyword is set, SPAWN does not switch the tty back to normal mode before launching the child process assuming instead that the child will not send output to the tty. Use this keyword to avoid characters being dropped in a loop of the form:

```
WHILE (GET_KBRD(0) NE 'q') SPAWN, command
```

This keyword has no effect on systems that don't suffer from dropped characters.

## NOWAIT (WINDOWS Only)

If this keyword is set, the IDL process continues executing in parallel with the subprocess. Normally, the IDL process suspends execution until the subprocess completes.

## NULL_STDIN

If set, the null device is connected to the standard input of the child process. The null device is either `/dev/null` (under UNIX) or NUL (under Windows).

## PID

A named variable into which the Process Identification number of the child process is stored.

## SH (UNIX Only)

Set this keyword to force the use of the Bourne shell (`/bin/sh`). Usually, the shell used is determined by the SHELL environment variable.

## STDERR

If set, the child's error output (stderr) is combined with the standard output and returned in *Result*. STDERR and the *ErrResult* argument are mutually exclusive. You should use one or the other, but not both.

## UNIT (UNIX Only)

If UNIT is present, SPAWN creates a child process in the usual manner, but instead of waiting for the specified command to finish, it attaches a bidirectional pipe between the child process and IDL. From the IDL session, the pipe appears as a logical file unit. The other end of the pipe is attached to the child process standard input and output. The UNIT keyword specifies a named variable into which the number of the file unit is stored.

Once the child process is started, the IDL session can communicate with it through the usual input/output facilities. After the child process has done its task, the CLOSE procedure can be used to kill the process and close the pipe. Since SPAWN uses GET_LUN to allocate the file unit, FREE_LUN should be used to free the unit.

If UNIT is present, *Command* must be present, and *Result* is not allowed.

## Obsolete Keywords

The following keywords are obsolete:

- FORCE
- MACCREATOR
- NOCLISYM
- NOLOGNAM
- NOTIFY

For information on obsolete keywords, See Appendix I, "Obsolete Features".

## Using SPAWN Without a Shell Under UNIX

When a Unix program is run, its name and arguments are provided to it as an array of strings, one string per argument. The first string is the name of the program, and the remainder (if any) are the arguments. C programmers will recognize this as the standard (argc, argv) arguments passed to the main() function when the program is run. When you execute a command via a Unix shell, one of the operations that the shell carries out for you is to split the command and arguments apart on whitespace boundaries (blanks and tabs) to create this array of arguments. It then runs the program for you, using one of the Unix system exec() functions.

By default, SPAWN creates a shell process and passes the command to this shell instead of simply creating a child process to directly execute the command. Use of a shell is the default because the shell provides useful facilities such as wildcard expansion and argument processing (described above). Although this is usually desirable, it has the drawback of being slower than necessary, and of using an additional process for the shell.

When SPAWN is called with the NOSHELL keyword set, the command is executed as a direct child process, avoiding the extra overhead of starting a shell. This is faster, but since there is no shell, you must specify the arguments in the standard form required by Unix programs. When you specify the NOSHELL keyword, the Command argument should be a string array. The first element of the array is the name of the command to use, and the following elements contain the arguments.

For example, consider the command,

```
SPAWN, 'ps ax'
```

that uses the UNIX *ps* command to show running processes on the computer. To issue this command without a shell, you would write it as follows:

```
SPAWN, ['ps', 'ax'], /NOSHELL
```

## Execution Directory under Microsoft Windows

SPAWN attempts to use IDL's current working directory as the current directory for the spawned process. However, Microsoft Windows does not support the specification of a UNC path as the current directory for a Command Shell. Issuing a SPAWN command when IDL's current working directory is set to a UNC path will cause Windows to generate an error that looks something like:

```
CMD.EXE was started with '\\host\dir' as the current directory
path. UNC paths are not supported.  Defaulting to Windows
directory.
```

If your application requires that you be able to use SPAWN when IDL's current working directory is set to a directory on a Windows network, consider mapping the UNC path to a Windows drive letter and setting that to be IDL's working directory.

# Examples

## Example 1: Interactive use of SPAWN

To simply spawn a shell process from within IDL, enter the command:

```
SPAWN
```

To execute the UNIX `ls` command and return to the IDL prompt, enter:

```
SPAWN, 'ls'
```

To execute the UNIX `ls` command and store the result in the IDL string variable `listing`, enter:

```
SPAWN, 'ls', listing
```

## Example 2: Noninteractive use of SPAWN

It is sometimes useful to create a temporary scratch file, removing the file when it is no longer needed. SPAWN could be used as shown below to manage the removal of the scratch file.

```
OPENW, UNIT, 'scratch.dat', /GET_LUN

;...IDL commands go here.

;Deallocate the file unit and close the file.
FREE_LUN, UNIT

;Use the !VERSION system variable to determine the proper file
;deletion command for the current operating system.
CASE !VERSION.OS OF
  'Windows': CMD = 'DEL'
  ELSE: CMD = 'rm'
ENDCASE

;Delete the file using SPAWN.
SPAWN, CMD + ' scratch.dat'

END
```

**Note**

The DELETE keyword to the OPEN procedure or the FILE_DELETE procedure more efficiently handles this job. The above example should serve only to demonstrate use of the SPAWN procedure.

## Version History

"Dollar Sign ($)" on page 3945, Chapter 2, "Using SPAWN and UNIX Pipes" in the *External Development Guide* manual

# SPH_4PNT

Given four 3-dimensional points, the SPH_4PNT procedure returns the center and radius necessary to define the unique sphere passing through those points.

This routine is written in the IDL language. Its source code can be found in the file `sph_4pnt.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

SPH_4PNT, *X*, *Y*, *Z*, *Xc*, *Yc*, *Zc*, *R* [, /DOUBLE]

## Arguments

### X, Y, Z

4-element floating-point or double-precision vectors containing the X, Y, and Z coordinates of the points.

### Xc, Yc, Zc

Named variables that will contain the sphere's center X, Y, and Z coordinates.

### R

A named variable that will contain the sphere's radius.

## Keywords

### DOUBLE

Set this keyword to force computations to be done in double-precision arithmetic.

## Examples

Find the center and radius of the unique sphere passing through the points: (1, 1, 0), (2, 1, 2), (1, 0, 3), (1, 0, 1):

```
; Define the floating-point vectors containing the x, y and z
; coordinates of the points:
X = [1, 2, 1, 1] + 0.0
Y = [1, 1, 0, 0] + 0.0
Z = [0, 2, 3, 1] + 0.0
```

```
; Compute sphere’s center and radius:
SPH_4PNT, X, Y, Z, Xc, Yc, Zc, R

; Print the results:
PRINT, Xc, Yc, Zc, R
```

IDL prints:

```
-0.500000      2.00000      2.00000      2.69258
```

## Version History

Introduced: Pre 4.0

CIR_3PNT, PNT_LINE

# SPH_SCAT

The SPH_SCAT function performs spherical gridding. Scattered samples on the surface of a sphere are interpolated to a regular grid. This routine is a convenient interface to the spherical gridding and interpolation provided by TRIANGULATE and TRIGRID.

This routine is written in the IDL language. Its source code can be found in the file `sph_scat.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = SPH_SCAT( *Lon*, *Lat*, *F* [, BOUNDS=*[lonmin, latmin, lonmax, latmax]*] [, BOUT=*variable*] [, GOUT=*variable*] [, GS=*[lonspacing, latspacing]*] [, NLON=*value*] [, NLAT=*value*] )

## Return Value

Returns a regularly-interpolated grid of the function.

## Arguments

### Lon

A vector of sample longitudes, in degrees.

**Note**

*Lon*, *Lat*, and *F* must all have the same number of points.

### Lat

A vector of sample latitudes, in degrees.

### F

A vector of data values which are functions of Lon and Lat. $F_i$ represents a value at ($Lon_i$, $Lat_i$).

# Keywords

## BOUNDS

Set this keyword to a four-element vector containing the grid limits in longitude and latitude of the output grid. The four elements are: [$Lon_{min}$, $Lat_{min}$, $Lon_{max}$, $Lat_{max}$]. If this keyword is not set, the grid limits are set to the extent of *Lon* and *Lat*.

**Note**

To cover all longitudes, you must explicitly specify the values for the BOUNDS keyword.

## BOUT

Set this keyword to a named variable that, on return, contains a four-element vector (similar to BOUNDS) that describes the actual extent of the regular grid.

## GOUT

Set this keyword to a named variable that, on return, contains a two-element vector (similar to GS) that describes the actual grid spacing.

## GS

Set this keyword to a two-element vector that specifies the spacing between grid points in longitude (the first element) and latitude (the second element).

If this keyword is not set, the default value is based on the extents of *Lon* and *Lat*. The default longitude spacing is ($Lon_{max}$ - $Lon_{min}$)/(NLON-1). The default latitude spacing is ($Lat_{max}$ - $Lat_{min}$)/(NLAT-1). If NLON and NLAT are not set, the default grid size of 26 by 26 is used for NLON and NLAT.

## NLON

The output grid size in the longitude direction. The default value is 26.

**Note**

NLON need not be specified if the size can be inferred from GS and BOUNDS.

## NLAT

The output grid size in the latitude direction. The default value is 26.

**Note**

NLAT need not be specified if the size can be inferred from GS and BOUNDS.

## Examples

```
; Create some random longitude points:
lon = RANDOMU(seed, 50) * 360. -180.

; Create some random latitude points:
lat = RANDOMU(seed, 50) * 180. -90.

; Make a function to fit:
z = SIN(lat*!DTOR)
c = COS(lat*!DTOR)
x = COS(lon*!DTOR) * c
y = SIN(lon*!DTOR) * c

; The finished dependent variable:
f = SIN(x+y) * SIN(x*z)
; Interpolate the data and return the result in variable r:
r = SPH_SCAT(lon, lat, f, BOUNDS=[0, -90, 350, 85], GS=[10,5])
```

# SPHER_HARM

The SPHER_HARM function returns the value of the spherical harmonic $Y_{lm}(\theta,\phi)$, $-l \le m \le l$, $l \ge 0$, which is a function of two coordinates on a spherical surface.

The spherical harmonics are related to the associated Legendre polynomial by:

$$Y_{lm}(\theta,\phi) = \sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}P_l^m(\cos\theta)e^{im\phi}$$

For negative *m* the following relation is used:

$$Y_{1,-m}(\theta,\phi) = (-1)^m Y_{lm}^*(\theta,\phi)$$

where * represents the complex conjugate.

This routine is written in the IDL language. Its source code can be found in the file `spher_harm.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = SPHER_HARM( *Theta*, *Phi*, *L*, *M*, [, /DOUBLE] )

## Return Value

SPHER_HARM returns a complex scalar or array containing the value of the spherical harmonic function. The return value has the same dimensions as the input arguments *Theta* and *Phi*. If one argument (*Theta* or *Phi*) is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If either *Theta* or *Phi* are double-precision or if the DOUBLE keyword is set, the result is double-precision complex, otherwise the result is single-precision complex.

## Arguments

### Theta

The value of the polar (colatitudinal) coordinate $\theta$ at which $Y_{lm}(\theta,\phi)$ is evaluated. *Theta* can be either a scalar or an array.

### Phi

The value of the azimuthal (longitudinal) coordinate ϕ at which $Y_{lm}(\theta,\phi)$ is evaluated. *Phi* can be either a scalar or an array.

### L

A scalar integer, $L \geq 0$, specifying the order *l* of $Y_{lm}(\theta,\phi)$. If *L* is of type float, it will be truncated.

### M

A scalar integer, $-L \leq M \leq L$, specifying the azimuthal order *m* of $Y_{lm}(\theta,\phi)$. If *M* is of type float, it will be truncated.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

This example visualizes the electron probability density for the hydrogen atom in state 3d0. (Feynman, Leighton, and Sands, 1965: The Feynman Lectures on Physics, Calif. Inst. Tech, Ch. 19):

```
; Define a data cube (N x N x N)
n = 41L
a = 60*FINDGEN(n)/(n-1) - 29.999  ; [-1,+1]
x = REBIN(a, n, n, n)              ; X-coordinates of cube
y = REBIN(REFORM(a,1,n), n, n, n)  ; Y-coordinates
z = REBIN(REFORM(a,1,1,n), n, n, n); Z-coordinates

; Convert from rectangular (x,y,z) to spherical (phi, theta, r)
spherCoord = CV_COORD(FROM_RECT= $
 TRANSPOSE([[x[*]],[y[*]],[z[*]]]), /TO_SPHERE)
phi = REFORM(spherCoord[0,*], n, n, n)
theta = REFORM(!PI/2 - spherCoord[1,*], n, n, n)
r = REFORM(spherCoord[2,*], n, n, n)

; Find electron probability density for hydrogen atom in state 3d0
; Angular component
L = 2   ; state "d" is electron spin L=2
M = 0   ; Z-component of spin is zero
angularState = SPHER_HARM(theta, phi, L, M)
```

```
; Radial component for state n=3, L=2
radialFunction = EXP(-r/2)*(r^2)
waveFunction = angularState*radialFunction
probabilityDensity = ABS(waveFunction)^2

SHADE_VOLUME, probabilityDensity, $
 0.1*MEAN(probabilityDensity), vertex, poly
oPolygon = OBJ_NEW('IDLgrPolygon', vertex, $
 POLYGON=poly, COLOR=[180,180,180])
XOBJVIEW, oPolygon
```

The results are shown in the following figure (rotated in XOBJVIEW for clarity):

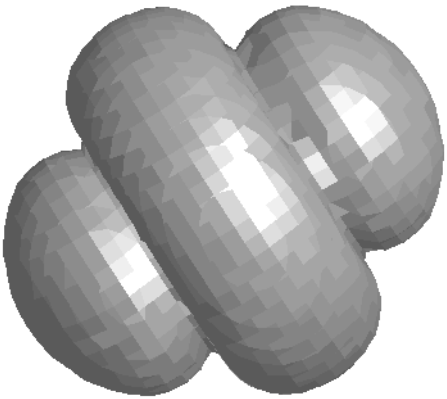

*Figure 29: SPHER_HARM Example of Hydrogen Atom (object rotated in XOBJVIEW for clarity)*

LEGENDRE, LAGUERRE

# SPL_INIT

The SPL_INIT function is called to establish the type of interpolating spline for a tabulated set of functional values $X_i$, $Y_i = F(X_i)$.

It is important to realize that SPL_INIT should be called only *once* to process an entire tabulated function in arrays *X* and *Y*. Once this has been done, values of the interpolated function for any value of *X* can be obtained by calls (as many as desired) to the separate function SPL_INTERP.

SPL_INIT is based on the routine spline described in section 3.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = SPL_INIT( *X*, *Y* [, /DOUBLE] [, YP0=*value*] [, YPN_1=*value*] )

## Return Value

Returns the values of the 2nd derivative of the interpolating function at the points $X_i$.

## Arguments

### X

An *n*-element input vector that specifies the tabulate points in ascending order.

### Y

An *n*-element input vector that specifies the values of the tabulated function $F(X_i)$ corresponding to $X_i$.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### YP0

The first derivative of the interpolating function at the point $X_0$. If YP0 is omitted, the second derivative at the boundary is set to zero, resulting in a “natural spline.”

### YPN_1

The first derivative of the interpolating function at the point $X_{n-1}$. If YPN_1 is omitted, the second derivative at the boundary is set to zero, resulting in a “natural spline.”

## Examples

### Example 1

```
X = (FINDGEN(21)/20.) * 2.0*!PI
Y = SIN(X)
PRINT, SPL_INIT(X, Y, YP0 = -1.1, YPN_1 = 0.0)
```

IDL Prints:

```
23.1552    -6.51599    1.06983   -1.26115  -0.839544    -1.04023
-0.950336  -0.817987  -0.592022  -0.311726  2.31192e-05  0.311634
 0.592347   0.816783   0.954825   1.02348   0.902068     1.02781
-0.198994   3.26597  -11.0260
```

### Example 2

```
PRINT, SPL_INIT(X, Y, YP0 = -1.1)
```

IDL prints:

```
23.1552    -6.51599    1.06983   -1.26115  -0.839544    -1.04023
-0.950336  -0.817988  -0.592020  -0.311732  4.41521e-05  0.311555

SPL_INTERP, SPLINE, SPLINE_P

# SPL_INTERP

Given the arrays *X* and *Y*, which tabulate a function (with the $X_i$ in ascending order), and given the array $Y_2$, which is the output from SPL_INIT, and given an input value of $X_2$, the SPL_INTERP function returns a cubic-spline interpolated value for the given value of $X_I$.

SPL_INTERP is based on the routine `splint` described in section 3.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = SPL_INTERP( *X*, *Y*, *Y2*, *X2* [, /DOUBLE] )

## Return Value

Returns either single- or double-precision floating result of the same structure as $X_2$.

## Arguments

### X

An input array that specifies the tabulated points in ascending order.

### Y

An input array that specifies the values of the tabulate function corresponding to $X_i$.

### Y2

The output from SPL_INIT for the specified *X* and *Y*.

### X2

The input value for which an interpolated value is desired. *X* can be scalar or an array of values. The result of SPL_INTERP will have the same structure.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

# Examples

To create a spline interpolation over a tabulated set of data, [$X_i$, $Y_i$], first create the tabulated data. In this example, $X_i$ will be in the range [0.0, $2\pi$] and $Y_i$ in the range [sin(0.0), sin($2\pi$)].

```
X = (FINDGEN(21)/20.0) * 2.0 * !PI
Y = SIN(X)

; Calculate interpolating cubic spline:
Y2 = SPL_INIT(X, Y)

; Define the X values P at which we desire interpolated Y values:
X2= FINDGEN(11)/11.0 * !PI

; Calculate the interpolated Y values corresponding to X2[i]:
result = SPL_INTERP(X, Y, Y2, X2)

PRINT, result
```

IDL prints:

```
 0.00000  0.281733  0.540638  0.755739  0.909613  0.989796
 0.989796  0.909613  0.755739  0.540638  0.281733
```

The exact solution vector is sin($X_2$).

To interpolate a line in the XY plane, see SPLINE_P.

# Version History

Introduced: 4.0

# See Also

SPL_INIT, SPLINE, SPLINE_P

# SPLINE

The SPLINE function performs cubic spline interpolation.

This routine is written in the IDL language. Its source code can be found in the file `spline.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = SPLINE( *X*, *Y*, *T* [, *Sigma*] )

## Return Value

Returns the result of the cubic spline interpolation.

## Arguments

### X

The abscissa vector. Values *must* be monotonically increasing.

### Y

The vector of ordinate values corresponding to *X*.

### T

The vector of abscissa values for which the ordinate is desired. The values of *T must* be monotonically increasing.

### Sigma

The amount of “tension” that is applied to the curve. The default value is 1.0. If sigma is close to 0, (e.g., .01), then effectively there is a cubic spline fit. If sigma is large, (e.g., greater than 10), then the fit will be like a polynomial interpolation.

## Keywords

None.

## Examples

The commands below show a typical use of SPLINE:

```
; X values of original function:
X = [2.,3.,4.]

; Make a quadratic
Y = (X-3)^2
;Values for interpolated points:
T = FINDGEN(20)/10.+2

; Do the interpolation:
Z = SPLINE(X,Y,T)
```

## Version History

Introduced: Original

## See Also

SPL_INIT, SPLINE_P

# SPLINE_P

The SPLINE_P procedure performs parametric cubic spline interpolation with relaxed or clamped end conditions.

This routine is both more general and faster than the SPLINE function. One call to SPLINE_P is equivalent to two calls to SPLINE, as both the X and Y are interpolated with splines. It is suited for interpolating between randomly placed points, and the abscissa values need not be monotonic. In addition, the end conditions may be optionally specified via tangents.

This routine is written in the IDL language. Its source code can be found in the file `spline_p.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

SPLINE_P, *X*, *Y*, *Xr*, *Yr* [, INTERVAL=*value*] [, TAN0=*[$X_0$, $Y_0$]*] [, TAN1=*[$X_{n-1}$, $Y_{n-1}$]*]

## Arguments

### X

The abscissa vector. *X* should be floating-point or double-precision.

### Y

The vector of ordinate values corresponding to X. *Y* should be floating-point or double-precision.

Neither X or Y need be monotonic.

### Xr

A named variable that will contain the abscissa values of the interpolated function.

### Yr

A named variable that will contain the ordinate values of the interpolated function.

# Keywords

## INTERVAL

Set this keyword equal to the desired interval in XY space between interpolants. If omitted, approximately 8 interpolants per XY segment will result.

## TAN0

The tangent to the spline curve at X[0], Y[0]. If omitted, the tangent is calculated to make the curvature of the result zero at the beginning. TAN0 is a two element vector, containing the X and Y components of the tangent.

## TAN1

The tangent to the spline curve at X[*n*-1], Y[*n*-1]. If omitted, the tangent is calculated to make the curvature of the result zero at the end. TAN1 is a two element vector, containing the X and Y components of the tangent.

# Examples

The commands below show a typical use of SPLINE_P:

```
; Abscissas for square with a vertical diagonal:
X = [0.,1,0,-1,0]

; Ordinates:
Y = [0.,1,2,1,0]

; Interpolate with relaxed end conditions:
SPLINE_P, X, Y, XR, YR

; Show it:
PLOT, XR, YR
```

As above, but with setting both the beginning and end tangents:

```
SPLINE_P, X, Y, XR, YR, TAN0=[1,0], TAN1=[1,0]
```

This yields approximately 32 interpolants.

As above, but with setting the interval to 0.05, making more interpolants, closer together:

```
SPLINE_P, X, Y, XR, YR, TAN0=[1,0], TAN1=[1,0], INTERVAL=0.05
```

This yields 116 interpolants and looks close to a circle.

## Version History

Introduced: Pre 4.0

SPL_INIT, SPLINE

# SPRSAB

The SPRSAB function performs matrix multiplication on two row-indexed sparse arrays created by SPRSIN. The routine computes all components of the matrix products, but only stores those values whose absolute magnitude exceeds the threshold value.

SPRSAB is based on the routine `sprstm` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission. The difference between the two routines is that SPRSAB performs the matrix multiplication A∗B rather than $A*B^T$.

## Syntax

*Result* = SPRSAB( *A*, *B* [, /DOUBLE] [, THRESHOLD=*value*] )

## Return Value

The result is a row-indexed sparse array.

## Arguments

### A, B

Row-indexed sparse arrays created by the SPRSIN function.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### THRESHOLD

Use this keyword to set the criterion for deciding the absolute magnitude of the elements to be retained in sparse storage mode. For single-precision calculations, the default value is $1.0 \times 10^{-7}$. For double-precision calculations, the default is $1.0 \times 10^{-14}$.

## Examples

```
; Begin by creating two arrays:
A = [[ 5.0,  0.0, 0.0,  1.0], $
     [ 3.0, -2.0, 0.0,  1.0], $
     [ 4.0, -1.0, 0.0,  2.0], $
     [ 0.0,  3.0, 3.0,  1.0]]
B = [[ 1.0,  2.0, 3.0,  1.0], $
     [ 3.0, -3.0, 0.0,  1.0], $
     [-1.0,  3.0, 1.0,  2.0], $
     [ 0.0,  3.0, 3.0,  1.0]]

; Convert the arrays to sparse array format before multiplying.
; The variable SPARSE holds the result in sparse array form:
sparse = SPRSAB(SPRSIN(A), SPRSIN(B))

; Restore the sparse array structure to full storage mode:
result = FULSTR(sparse)

; Print the result:
PRINT, 'result:'
PRINT, result

; Check this result by multiplying the original arrays:
exact = B # A
PRINT, 'exact:'
PRINT, exact
```

IDL prints:

```
result:
 5.00000      13.0000      18.0000       6.00000
-3.00000      15.0000      12.0000       2.00000
 1.00000      17.0000      18.0000       5.00000
 6.00000       3.00000      6.00000      10.0000
exact:
 5.00000      13.0000      18.0000       6.00000
-3.00000      15.0000      12.0000       2.00000
 1.00000      17.0000      18.0000       5.00000

FULSTR, LINBCG, SPRSAX, SPRSIN, SPRSTP, READ_SPR, WRITE_SPR

# SPRSAX

The SPRSAX function takes a row-indexed sparse array created by the SPRSIN function and multiplies it by an *n*-element vector to its right.

SPRSAX is based on the routine `sprsax` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = SPRSAX( *A*, *X* [, /DOUBLE] )

## Return Value

Returns a *n*-element vector.

## Arguments

### A

A row-indexed sparse array created by the SPRSIN function.

### X

An *n*-element right hand vector.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Begin by creating an array A:
A = [[ 5.0,  0.0, 0.0], $
     [ 3.0, -2.0, 0.0], $
     [ 4.0, -1.0, 0.0]]

; Define the right-hand vector:
X = [1.0, 2.0, -1.0]
```

```
; Convert to sparse format, then multiply by X:
result = SPRSAX(SPRSIN(A),X)

; Print the result:
PRINT, result
```

IDL prints:

```
5.00000     -1.00000      2.00000
```

## Version History

Introduced: 4.0

## See Also

FULSTR, LINBCG, SPRSAB, SPRSIN, SPRSTP, READ_SPR, WRITE_SPR

# SPRSIN

The SPRSIN function converts an array, or list of subscripts and values, into a row-index sparse storage mode, retaining only elements with an absolute magnitude greater than or equal to the specified threshold. The list form is much more efficient than the array form if the density of the matrix is low.

SPRSIN is based on the routine `sprsin` described in section 2.7 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = SPRSIN( *A* [, /COLUMN] [, /DOUBLE] [, THRESHOLD=*value*] )

or

*Result* = SPRSIN(*Columns*, *Rows*, *Values*, *N* [, /DOUBLE] [, THRESHOLD=*value*])

## Return Value

The result is a row-indexed sparse array contained in structure form. The structure consists of two linear sparse storage vectors: SA, a vector of array values, and IJA, a vector of subscripts to the SA vector. The length of these vectors is equal to 1 plus the number of diagonal elements of the array, plus the number of off-diagonal elements with an absolute magnitude greater that or equal to the threshold value. Diagonal elements of the array are always retained even if their absolute magnitude is less than the specified threshold.

## Arguments

### A

An *n* by *n* array of any type except string or complex.

### Columns

A vector containing the column subscripts of the non-zero elements. Values must be in the range of 0 to (N-1).

### Rows

A vector, of the same length as Column, containing the row subscripts of the non-zero elements. Values must be in the range of 0 to (N-1).

### Values

A vector, of the same length as Column, containing the values of the non-zero elements.

### N

The size of the resulting sparse matrix.

## Keywords

### COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors). This keyword is not allowed in the list form of the call.

### DOUBLE

Set this keyword to convert the sparse array to double-precision.

### THRESHOLD

Use this keyword to set the criterion for deciding the absolute magnitude of the elements to be retained in sparse storage mode. For single-precision calculations, the default value is $1.0 \times 10^{-7}$. For double-precision values, the default is $1.0 \times 10^{-14}$.

## Examples

### Example1

Suppose we wish to convert the following array to sparse storage format:

```
A = [[ 5.0, -0.2, 0.1], $
     [ 3.0, -2.0, 0.3], $
     [ 4.0, -1.0, 0.0]]

; Convert to sparse storage mode. All elements of the array A that
; have absolute values less than THRESH are set to zero.
sparse = SPRSIN(A, THRESH = 0.5)
```

The variable SPARSE now contains a representation of A in structure form. See the description of FULSTR for an example that restores such a structure to full storage mode.

### Example2

This example demonstrates how to use the list form of the call to SPRSIN. The following line of code creates a sparse matrix, equivalent to a 100 by 100 identity matrix, i.e. all diagonal elements are set to 1, all other elements are zero:

```
I100 = SPRSIN(LINDGEN(100), LINDGEN(100), REPLICATE(1.0,100), 100)
```

## Version History

Introduced: 4.0

## See Also

FULSTR, LINBCG, SPRSAB, SPRSAX, SPRSTP, READ_SPR, WRITE_SPR

# SPRSTP

The SPRSTP function constructs the transpose of a sparse matrix.

## Syntax

*Result* = SPRSTP(*A*)

## Return Value

Returns the sparse matrix of the given sparse array.

## Arguments

### A

A row-indexed sparse array created by the SPRSIN function.

## Keywords

None

## Examples

This example creates a 100 by 100 pseudo-random sparse matrix, with 1000 non-zero elements, and then computes the product of the matrix and its transpose:

```
n = 100                    ;Dimensions of matrix
m = 1000                   ;Number of non-zero elements
a = SPRSIN(RANDOMU(seed, m)*n, RANDOMU(seed, m)*n, $
    RANDOMU(seed, m),n)
b = SPRSAB(a, SPRSTP(a))  ;Transpose and create the product
```

## Version History

Introduced: 4.0

## See Also

FULSTR, LINBCG, SPRSAB, SPRSAX, SPRSIN, READ_SPR, WRITE_SPR

# SQRT

The SQRT function computes the square root of *X*.

## Syntax

*Result* = SQRT(*X*)

## Return Value

Returns the square root of *X*.

## Arguments

### X

The value for which the square root is desired. If *X* is double-precision floating-point or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. When applied to complex numbers, $z = x+iy$:

$$z^{1/2} = \left[\frac{1}{2}(r + x)\right]^{1/2} \pm i\left[\frac{1}{2}(r - x)\right]^{1/2}$$

$$r = \sqrt{x^2 + y^2}$$

The ambiguous sign is taken to be the same as the sign of *y*. The result has the same structure as *X*.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

## Examples

To find the square root of 145 and store the result in variable S, enter:

```
S = SQRT(145)
```

## Version History

Introduced: Original

## See Also

"Exponentiation" in Chapter 2 of the *Building IDL Applications* manual.

# STANDARDIZE

The STANDARDIZE function computes standardized variables from an array of *m* variables (columns) and *n* observations (rows).

This routine is written in the IDL language. Its source code can be found in the file `standardize.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = STANDARDIZE( *A* [, /DOUBLE] )

## Return Value

The result is an *m*-column, *n*-row array where all columns have a mean of zero and a variance of one.

## Arguments

### A

An *m*-column, *n*-row single- or double-precision floating-point array.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Define an array with 4 variables and 20 observations:
array = $
          [[19.5, 43.1, 29.1, 11.9], $
           [24.7, 49.8, 28.2, 22.8], $
           [30.7, 51.9, 37.0, 18.7], $
           [29.8, 54.3, 31.1, 20.1], $
           [19.1, 42.2, 30.9, 12.9], $
           [25.6, 53.9, 23.7, 21.7], $
           [31.4, 58.5, 27.6, 27.1], $
           [27.9, 52.1, 30.6, 25.4], $
           [22.1, 49.9, 23.2, 21.3], $
           [25.5, 53.5, 24.8, 19.3], $
```

```
                [31.1, 56.6, 30.0, 25.4], $
                [30.4, 56.7, 28.3, 27.2], $
                [18.7, 46.5, 23.0, 11.7], $

MOMENT

# STDDEV

The STDDEV function computes the standard deviation of an *n*-element vector.

## Syntax

*Result* = STDDEV( *X* [, /DOUBLE] [, /NAN] )

## Return Value

The result is the standard deviation of the given vector.

## Arguments

### X

A numeric vector.

## Keywords

### DOUBLE

If this keyword is set, computations are performed in double precision arithmetic.

### NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point value NaN in the input data. Elements with the value NaN are treated as missing data. (See "Special Floating-Point Values" in Chapter 18 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## Examples

```
; Define the n-element vector of sample data:
x = [65, 63, 67, 64, 68, 62, 70, 66, 68, 67, 69, 71, 66, 65, 70]

; Compute the standard deviation:
result = STDDEV(x)

PRINT, result
```

IDL prints:

```
2.65832
```

## Version History

Introduced: 5.1

KURTOSIS, MEAN, MEANABSDEV, MOMENT, SKEWNESS, VARIANCE

# STOP

The STOP procedure stops the execution of a running program or batch file. Control reverts to the interactive mode.

## Syntax

STOP [, *Expr*$_1$, ..., *Expr*$_n$]

## Arguments

### Expr$_i$

One or more expressions whose value is printed. If no parameters are present, a brief message describing where the STOP was encountered is printed.

## Keywords

None.

## Examples

Suppose that you want to stop the execution of a procedure and print the values of the variables A, B, C and NUM. At the appropriate location in your procedure include the command:

```
STOP, A, B, C, NUM
```

To continue execution of the procedure (if possible) enter the IDL executive command:

```
.CONT
```

BREAKPOINT, EXIT, WAIT

# STRARR

The STRARR function returns a string array containing zero-length strings.

## Syntax

*Result* = STRARR($D_1$ [, ..., $D_8$])

## Return Value

The result is a string array of the specified dimensions.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Examples

To create S, a 20-element string vector, enter:

```
S = STRARR(20)
```

## Version History

Introduced: Original

# STRCMP

The STRCMP function performs string comparisons between its two String arguments, returning True (1) for those that match and False (0) for those that do not. Normally, the IDL equality operator (EQ) is used for such comparisons, but STRCMP can optionally perform case-insensitive comparisons and can be limited to compare only the first N characters of the two strings, both of which require extra steps using the EQ operator.

## Syntax

*Result* = STRCMP( *String1*, *String2* [, *N*] [, /FOLD_CASE] )

## Return Value

If all of the arguments are scalar, the result is scalar. If one of the arguments is an array, the result is an integer with the same structure. If more than one argument is an array, the result has the structure of the smallest array. Each element of the result contains True (1) if the corresponding elements of String1 and String2 are the same, and False (0) otherwise.

## Arguments

### String1, String2

The strings to be compared.

### N

Normally String1 and String2 are compared in their entirety. If N is specified, the comparison is made on at most the first N characters of each string.

## Keywords

### FOLD_CASE

String comparison is normally a case sensitive operation. Set FOLD_CASE to perform case insensitive comparisons instead.

## Examples

Compare two strings in a case-insensitive manner, considering only the first 3 characters:

```
Result = STRCMP('Moose', 'moo', 3, /FOLD_CASE)
PRINT, Result
```

IDL prints:

```
       1
```

## Version History

Introduced: 5.3

## See Also

# STRCOMPRESS

The STRCOMPRESS function returns a copy of *String* with all whitespace (blanks and tabs) compressed to a single space or completely removed.

## Syntax

*Result* = STRCOMPRESS( *String* [, /REMOVE_ALL] )

## Return Value

The result is a compressed string.

## Arguments

### String

The string to be compressed. If not of type string, it is converted using IDL's default formatting rules. If *String* is an array, the result is an array with the same structure—each element contains a compressed copy of the corresponding element of *String*.

## Keywords

### REMOVE_ALL

Set this keyword to remove *all* whitespace. Normally, all whitespace is compressed to a *single* space.

## Examples

```
; Create a string variable S:
S = 'This is a string with spaces in it.'

; Print S with all of the whitespace removed:
PRINT, STRCOMPRESS(S, /REMOVE_ALL)
```

### IDL Output

```
Thisisastringwithspacesinit.
```

## Version History

Introduced: Original

STRTRIM

# STREAMLINE

The STREAMLINE procedure generates the visualization graphics from a path. The output is a polygonal ribbon which is tangent to a vector field along its length. The ribbon is generated by placing a line at each vertex in the direction specified by each normal value multiplied by the anisotropy factor. The input normal array is not normalized before use, making it possible to vary the ribbon width as well.

## Syntax

STREAMLINE, *Verts*, *Conn*, *Normals*, *Outverts*, *Outconn* [, ANISOTROPY=*array*] [, SIZE=*vector*] [, PROFILE=*array*]

## Arguments

### Verts

Input array of path vertices ([3, *n*] array).

### Conn

Input path connectivity array in IDLgrPolyline POLYLINES keyword format. There is one set of line segments in this array for each streamline.

### Normals

Normal estimate at each input vertex ([3, *n*] array).

### Outverts

Output vertices ([3xn] float array). Useful if the routine is to be used with Direct Graphics or the user wants to manipulate the data directly.

### Outconn

Output polygonal connectivity array to match the output vertices.

## Keywords

### ANISOTROPY

Set this input keyword to a three-element array describing the distance between grid points in each dimension. The default value is [1.0, 1.0, 1.0]

### SIZE

Set this keyword to a vector of values (one for each path point). These values are used to specify the width of the ribbon or the size of profile at each point along its path. This keyword is generally used to convey additional data parameters along the streamline.

### PROFILE

Set this keyword to an array of two-dimensional points which are treated as the cross section of the ribbon instead of a line segment. If the first and last points in the array are the same, a closed profile is generated. The profile is placed at each path vertex in the plane perpendicular to the line connecting each path vertex with the vertex normal defining the up direction. This allows for the generation of streamtubes and other geometries.

## Version History

Introduced: 5.3

# STREGEX

The STREGEX function performs regular expression matching against the strings contained in StringExpression. STREGEX can perform either a simple boolean True/False evaluation of whether a match occurred, or it can return the position and offset within the strings for each match. The regular expressions accepted by this routine, which correspond to “Posix Extended Regular Expressions”, are similar to those used by such UNIX tools as egrep, lex, awk, and Perl.

For more information about regular expressions, see “Learning About Regular Expressions” in Chapter 5 of the *Building IDL Applications* manual.

STREGEX is based on the regex package written by Henry Spencer, modified by RSI only to the extent required to integrate it into IDL. This package is freely available at `ftp://zoo.toronto.edu/pub/regex.shar`.

## Syntax

*Result* = STREGEX( *StringExpression*, *RegularExpression* [, /BOOLEAN | , /EXTRACT | , LENGTH=*variable* [, /SUBEXPR]] [, /FOLD_CASE] )

## Return Value

By default, STREGEX returns the position and length of the matched string within StringExpression. If no match is found, -1 is returned for both of these. Optionally, it can return a Boolean True/False result of the match, or the matched strings.

## Arguments

### StringExpression

String to be matched.

### RegularExpression

A scalar string containing the regular expression to match. See “Learning About Regular Expressions” in Chapter 5 of the *Building IDL Applications* manual for a description of the meta characters that can be used in a regular expression.

# Keywords

## BOOLEAN

Normally, STREGEX returns the position of the first character in StringExpression that matches RegularExpression. Setting BOOLEAN modifies this behavior to simply return a True/False value indicating if a match occurred or not.

## EXTRACT

Normally, STREGEX returns the position of the first character in StringExpression that matches RegularExpression. Setting EXTRACT modifies this behavior to simply return the matched substrings. The EXTRACT keyword cannot be used with either BOOLEAN or LENGTH.

## FOLD_CASE

Regular expression matching is normally a case-sensitive operation. Set FOLD_CASE to perform case-insensitive matching instead.

## LENGTH

If present, specifies a variable to receive the lengths of the matches. Together with this result of this function, which contains the starting points of the matches in StringExpression, LENGTH can be used with the STRMID function to extract the matched substrings. The LENGTH keyword cannot be used with either BOOLEAN or EXTRACT.

## SUBEXPR

By default, STREGEX only reports the overall match. Setting SUBEXPR causes it to report the overall match as well as any subexpression matches. A subexpression is any part of a regular expression written within parentheses. For example, the regular expression ‘(a)(b)(c+)’ has 3 subexpressions, whereas the functionally equivalent 'abc+' has none. The SUBEXPR keyword cannot be used with BOOLEAN.

If a subexpression participated in the match several times, the reported substring is the last one it matched. Note, as an example in particular, that when the regular expression ‘(b*)+’ matches ‘bbb’, the parenthesized subexpression matches the three 'b's and then an infinite number of empty strings following the last ‘b’, so the reported substring is one of the empties. This occurs because the ‘*’ matches *zero or more* instances of the character that precedes it.

In order to return multiple positions and lengths for each input, the result from SUBEXPR has a new first dimension added compared to StringExpression.

# Examples

## Example 1

To match a string starting with an “a”, followed by a “b”, followed by 1 or more “c”:

```
pos = STREGEX('aaabccc', 'abc+', length=len)
PRINT, STRMID('aaabccc', pos, len)
```

IDL Prints:

```
abccc
```

To perform the same match, and also find the locations of the three parts:

```
pos = STREGEX('aaabccc', '(a)(b)(c+)', length=len, /SUBEXPR)
print, STRMID('aaabccc', pos, len)
```

IDL Prints:

```
abccc a b ccc
```

Or more simply:

```
print,STREGEX('aaabccc','(a)(b)(c+)',/SUBEXPR,/EXTRACT)
```

IDL Prints:

```
abccc a b ccc
```

## Example 2

This example searches a string array for words of any length beginning with “f” and ending with “t” without the letter “o” in between:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'affluent']
PRINT, STREGEX(str, '^f[^o]*t$', /EXTRACT, /FOLD_CASE)
```

This statement results in:

```
Feet FAST ferret
```

Note the following about this example:

- Unlike the * wildcard character used by STRMATCH, the * meta character used by STREGEX applies to the item directly on its left, which in this case is [^o], meaning “any character except the letter ‘o’ ”. Therefore, [^o]* means “zero or more characters that are not ‘o’ ”, whereas the following statement would find only words whose second character is not “o”:

```
PRINT, str[WHERE(STRMATCH(str, 'f[!o]*t', /FOLD_CASE) EQ 1)]
```

- The anchors (^ and $) tell STREGEX to find only words that begin with “f” and end with “t”. If we left out the ^ anchor in the above example, STREGEX would also return “ffluent” (a substring of “affluent”). Similarly, if we left out the $ anchor, STREGEX would also return “fat” (a substring of “fate”).

STRCMP, STRJOIN, STRMATCH, STRMID, STRPOS, STRSPLIT

# STRETCH

The STRETCH procedure stretches the image display color tables so the full range runs from one color index to another. The modified colortable is loaded, but the COLORS common block is not changed. The original colortable can be restored by calling STRETCH with no arguments. A colortable must be loaded before STRETCH can be called.

This routine is written in the IDL language. Its source code can be found in the file `stretch.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

STRETCH [, *Low*, *High* [, *Gamma*]] [, /CHOP]

## Arguments

### Low

The lowest pixel value to use. If this parameter is omitted, 0 is assumed. Appropriate values range from 0 to the number of available colors-1. If no parameters are supplied, the original color tables are restored.

### High

The highest pixel value to use. If this parameter is omitted, the number of colors-1 is assumed. Appropriate values range from 0 to the number of available colors-1.

### Gamma

An optional Gamma correction factor. If this value is omitted, 1.0 is assumed. Gamma correction works by raising the color indices to the *Gamma* power, assuming they are scaled into the range 0 to 1.

## Keywords

### CHOP

Set this keyword to set color indices above the upper threshold to color index 0. Normally, values above the upper threshold are set to the maximum color index.

## Examples

Load the STD GAMMA-II color table by entering:

```
LOADCT, 5
```

Create and display and image by entering:

```
TVSCL, DIST(300)
```

Now adjust the color table with STRETCH. Make the entire color table fit in the range 0 to 70 by entering:

```
STRETCH, 0, 70
```

Notice that pixel values above 70 are now colored white. Restore the original color table by entering:

```
STRETCH
```

## Version History

Introduced: Original

GAMMA_CT, H_EQ_CT, MULTI, XLOADCT

# STRING

The STRING function returns its arguments converted to string type. It is similar to the PRINT procedure, except that its output is placed in a string rather than being output to the terminal. The case in which a single expression of type byte is specified without the FORMAT keyword is special—see the “Differences Between STRING and PRINT” on page 1901 for details.

**Note**

Applying the STRING function to a byte array containing a null (zero) value will result in the resulting string being truncated at that position.

## Syntax

*Result* = STRING( *Expression*$_1$, ..., *Expression*$_n$ [, AM_PM=*[string, string]*] [, DAYS_OF_WEEK=*string_array*{7 names}] [, FORMAT=*value*] [, MONTHS=*string_array*{12 names}] [, /PRINT] )

## Return Value

Returns a string containing the specified expression.

## Arguments

### Expression$_n$

The expressions to be converted to string type.

**Note**

If you supply a comma-separated list of expressions without specifying a FORMAT, and the combined length of the expressions is greater than the current width of your tty or command log window, STRING will create a string array with one element for each expression, rather than concatenating all expressions into a single string. In this case, you can either specify a FORMAT, or use the string concatenation operator, “+”.

# Keywords

## AM_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

## DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

## FORMAT

A format string to be used in formatting the expressions. See "Using Explicitly Formatted Input/Output" in Chapter 10 of the *Building IDL Applications* manual.

## MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

## PRINT

Set this keyword to specify that any special case processing should be ignored and that STRING should behave exactly as the PRINT procedure would.

# Differences Between STRING and PRINT

The behavior of STRING differs from the behavior of the PRINT procedure in the following ways (unless the PRINT keyword is set):

- When called with a single non-byte argument and no format specification, STRING returns a result that has the same dimensions as the original argument. For example, the statement:

  ```
  HELP, STRING(INDGEN(5))
  ```

  gives the result:

  ```
  <Expression> STRING = Array[5]
  ```

while:

```
HELP, STRING(INDGEN(5), /PRINT)
```

results in:

```
<Expression> STRING =' 0 1 2 3 4'
```

- If called with a single argument of byte type and the FORMAT keyword is not used, STRING simply stores the unmodified values of each byte element in the result. This result is a string containing the byte values from the original argument. Thus, the result has one less dimension than the original argument. For example, a 2-dimensional byte array becomes a vector of strings, a byte vector becomes a scalar string. However, a byte scalar also becomes a string scalar. For example, the statement:

  ```
  PRINT, STRING([72B, 101B, 108B, 108B, 111B])
  ```

  produces the output:

  ```
  Hello
  ```

  because the argument to STRING, is a byte vector. Its first element is a 72B which is the ASCII code for “H”, the second is 101B which is an ASCII “e”, and so forth.

- If both the FORMAT and PRINT keywords are not present and STRING is called with more than one argument, and the last argument is a scalar string starting with the characters “$(” or “(”, this final argument is taken to be the format specification, just as if it had been specified via the FORMAT keyword. This feature is maintained for compatibility with version 1 of VMS IDL.

## Examples

To convert the contents of variable A to string type and store the result in the variable B, enter:

```
B = STRING(A)
```

## Version History

Introduced: Original

# STRJOIN

The STRJOIN function collapses a string scalar or array into merged strings. This function reduces the rank of its input array by one dimension. The strings in the removed first dimension are concatenated into a single string using the string in *Delimiter* to separate them.

## Syntax

*Result* = STRJOIN( *String* [, *Delimiter*] [, /SINGLE] )

## Return Value

Returns the merged strings.

## Arguments

### String

A string scalar or array to be collapsed into merged strings.

### Delimiter

The separator string to use between the joined strings. If Delimiter is not specified, an empty string is used.

## Keywords

### SINGLE

If SINGLE is set, the entire String is joined into a single scalar string result.

## Examples

Replace all the blanks in a sentence with colons:

```
str = 'Out, damned spot! Out I say!'
print, (STRJOIN(STRSPLIT(str, /EXTRACT), ':'))
```

IDL prints:

```
Out,:damned:spot!:Out:I:say!
```

## Version History

Introduced: 5.3

## See Also

STRCMP, STREGEX, STRMATCH, STRMID, STRPOS, STRSPLIT

# STRLEN

The STRLEN function returns the length of its string-type argument. If the argument is not a string, it is first converted to string type.

## Syntax

*Result* = STRLEN(*Expression*)

## Return Value0

Returns the string length.

## Arguments

### Expression

The expression for which the string length is desired. If this parameter is not a string, it is converted using IDL's default formatting rules in order to determine the length. The result is a long integer. If *Expression* is an array, the result is a long integer array with the same structure, where each element contains the length of the corresponding *Expression* element.

## Keywords

None.

## Examples

To find the length of the string "IDL is fun" and print the result, enter:

```
PRINT, STRLEN('IDL is fun')
```

IDL prints:

```
      10
```

## Version History

Introduced: Original

# STRLOWCASE

The STRLOWCASE function returns a copy of *String* converted to lowercase characters. Only uppercase characters are modified—lowercase and non-alphabetic characters are copied without change.

## Syntax

*Result* = STRLOWCASE(*String*)

## Return Value

Returns a string composed of lowercase characters.

## Arguments

### String

The string to be converted. If this argument is not a string, it is converted using IDL's default formatting rules. If *String* is an array, the result is an array with the same structure—each element contains a lower case copy of the corresponding element of *String*.

## Keywords

None.

## Examples

To convert the string "IDL is fun" to all lowercase characters and print the result, enter:

```
PRINT, STRLOWCASE('IDL is fun')
```

IDL prints:

```
idl is fun
```

## Version History

Introduced: Original

## See Also

STRUPCASE

# STRMATCH

The STRMATCH function compares its search string, which can contain wildcard characters, against the input string expression. The result is an array with the same structure as the input string expression. Those elements that match the corresponding input string are set to True (1), and those that do not match are set to False (0).

The wildcards understood by STRMATCH are similar to those used by the standard UNIX shell:

| Wildcard Character | Description |
|---|---|
| * | Matches any string, including the null string. |
| ? | Matches any single character. |
| [...] | Matches any one of the enclosed characters. A pair of characters separated by "-" matches any character lexically between the pair, inclusive. If the first character following the opening [ is a !, any character not enclosed is matched. To prevent one of these characters from acting as a wildcard, it can be quoted by preceding it with a backslash character (e.g. "*" matches the asterisk character). Quoting any other character (including \ itself) is equivalent to the character (e.g. "\a" is the same as "a"). |

*Table 92: Wildcard Characters used by STRMATCH*

## Syntax

*Result* = STRMATCH( *String*, *SearchString* [, /FOLD_CASE] )

## Return Value

Returns 1 if the pattern specified by *SearchString* exists in *String*, or 0 otherwise. If the *String* argument contains an array of strings, the result is an array of 1s and 0s with the same number of elements as *String*, indicating which elements contain *SearchString*.

# Arguments

## String

A scalar string or string array to be searched.

## SearchString

A scalar string containing the pattern to search for in *String*. The pattern string can contain wildcard characters as discussed above.

# Keywords

## FOLD_CASE

The comparison is usually case sensitive. Setting the FOLD_CASE keyword causes a case insensitive match to be done instead.

# Examples

## Example 1

Find all 4-letter words in a string array that begin with “f” or “F” and end with “t” or “T”:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f??t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet FAST fort
```

## Example 2

Find words of any length that begin with “f” and end with “t”:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f*t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet FAST ferret fort
```

### Example 3

Find 4-letter words beginning with “f” and ending with “t”, with any combination of “o” and “e” in between:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f[eo][eo]t', /FOLD_CASE) EQ 1)]
```

This results in:

```
foot Feet
```

### Example 4

Find all words beginning with “f” and ending with “t” whose second character is not the letter “o”:

```
str = ['foot', 'Feet', 'fate', 'FAST', 'ferret', 'fort']
PRINT, str[WHERE(STRMATCH(str, 'f[!o]*t', /FOLD_CASE) EQ 1)]
```

This results in:

```
Feet FAST ferret
```

# STRMESSAGE

The STRMESSAGE function returns the text of the error message specified by *Err*. This function is especially useful in conjunction with the CODE field of the !ERROR_STATE system variable which always contains the error number of the last error. The MSG field of the !ERROR_STATE system variable contains the text of the last error message.

## Syntax

*Result* = STRMESSAGE( *Err* [, /BLOCK | , /CODE | , /NAME] )

## Return Value

Returns the error message text.

## Arguments

### Err

The error number or text. Programs must not make the assumption that certain error numbers are always related to certain error messages—the actual correspondence changes over time as IDL is modified.

## Keywords

### BLOCK

Set this keyword to return the name of the message block that defines *Err*. If this keyword is specified, *Err* must be an error code.

### CODE

Set this keyword to return the error code for the error message specified in *Err*. If this keyword is specified, *Err* must be an error name.

### NAME

Set this keyword to return a string containing the error message that goes with *Err*. If this keyword is specified, *Err* must be an error code.

## Examples

Print the error message associated with error number 4 by entering:

```
PRINT, STRMESSAGE(4)
```

## Version History

Introduced: Original

MESSAGE

# STRMID

The STRMID function extracts one or more substring from a string expression. Each extracted string is the result of removing characters.

## Syntax

*Result* = STRMID(*Expression*, *First_Character* [, *Length*] [, /REVERSE_OFFSET])

## Return Value

The result of the function is a string of *Length* characters taken from *Expression*, starting at character position *First_Character*.

The form of *First_Character* and *Length* control how they are applied to *Expression*. Either argument can be a scalar or an array:

- If a scalar value is supplied for *First_Character* and *Length*, then those values are applied to all elements of *Expression*. The result has the same structure and number of elements as *Expression*.

If *First_Character* or *Length* is an array, the size of their first dimension determines how many substrings are extracted from each element of *Expression*. We call this the “stride”. If both are arrays, they must have the same stride. If *First_Character* or *Length* do not contain enough elements to process *Expression*, STRMID automatically loops back to the beginning as necessary. Excess values are ignored. If the stride is 1, the result will have the same structure and number of elements as *Expression*. If it is greater than 1, the result will have an additional dimension, with the new first dimension having the same size as the stride.

## Arguments

### Expression

The expression from which the substrings are to be extracted. If this argument is not a string, it is converted using IDL's default formatting rules.

### First_Character

The starting position within *Expression* at which the substring starts. The first character position is 0.

### Length

The length of the substring. If there are not enough characters left in the main string to obtain *Length* characters, the substring is truncated. If *Length* is not supplied, STRMID extracts all characters from the specified start position to the end of the string.

## Keywords

### REVERSE_OFFSET

Specifies that *First_Character* should be counted from the end of the string backwards. This allows simple extraction of strings from the end.

## Examples

If the variable B contains the string “IDL is fun”, the substring “is” can be extracted and stored in the variable C with the command:

```
C = STRMID(B, 4, 2)
```

STRPOS, STRPUT, STRTRIM

# STRPOS

The STRPOS function finds the first occurrence of a substring within an object string.

## Syntax

*Result* = STRPOS( *Expression*, *Search String* [, *Pos*] [, /REVERSE_OFFSET] [, /REVERSE_SEARCH] )

## Return Value

If *Search_String* occurs in *Expression*, STRPOS returns the character position of the match, otherwise it returns -1.

## Arguments

### Expression

The expression in which to search for the substring. If this argument is not a string, it is converted using IDL's default formatting rules. If *Expression* is an array, the result is an array with the same structure, where each element contains the position of the substring within the corresponding element *Expression*. If *Expression* is the null string, STRPOS returns the value -1.

### Search_String

The substring to be searched for within *Expression*. If this argument is not a string, it is converted using IDL's default formatting rules. If *Search_String* is the null string, STRPOS returns the smaller of *Pos* or one less than the length of *Expression*.

### Pos

The character position at which the search is begun. If *Pos* is omitted and the REVERSE_SEARCH keyword is not set, the search begins at the first character (character position 0). If REVERSE_SEARCH is set, the default is to start at the last character in the string. If *Pos* is less than zero, zero is used for the starting position.

# Keywords

## REVERSE_OFFSET

Normally, the value of *Pos* is used as an offset from the beginning of the expression towards the end. Set REVERSE_OFFSET to use it as an offset from the last character of the string moving towards the beginning. This keyword makes it easy to position the starting point of the search at a fixed offset from the end of the string.

## REVERSE_SEARCH

STRPOS usually starts at *Pos* and moves toward the end of the string looking for a match. If REVERSE_SEARCH is set, the search instead moves towards the beginning of the string.

# Examples

## Example 1

Find the position of the string “fun” within the string “IDL is fun” and print the result by entering:

```
PRINT, STRPOS('IDL is fun', 'fun')
```

IDL prints:

```
      7
```

## Example 2

The REVERSE_SEARCH keyword to the STRPOS function makes it easy to find the last occurrence of a substring within a string. In the following example, we search for the last occurrence of the letter “I” (or “i”) in a sentence:

```
sentence = 'IDL is fun.'
sentence = STRUPCASE(sentence)
lasti = STRPOS(sentence, 'I', /REVERSE_SEARCH)
PRINT, lasti
```

This results in:

```
4
```

Note that although REVERSE_SEARCH tells STRPOS to begin searching from the end of the string, the STRPOS function still returns the position of the search string from the beginning of the string (where 0 is the position of the first character).

## Version History

Introduced: Original

## See Also

STRMID, STRPUT, STRTRIM

# STRPUT

The STRPUT procedure inserts the contents of one string into another. The source string, *Source*, is inserted into the destination string, *Destination*, starting at the given position, *Position*. Characters in *Destination* before the starting position and after the starting position plus the length of *Source* remain unchanged. The length of the destination string is not changed. If the insertion extends past the end of the destination, it is clipped at the end.

## Syntax

STRPUT, *Destination*, *Source* [, *Position*]

## Arguments

### Destination

The named string variable into which *Source* is inserted. *Destination* must be a named variable of type string. If it is an array, *Source* is inserted into every element of the array.

### Source

A scalar string to be inserted into *Destination*. If this argument is not a string, it is converted using IDL's default formatting rules.

### Position

The character position at which the insertion is begun. If *Position* is omitted, the insertion begins at the first character (character position 0). If *Position* is less than zero, zero is used for the initial position.

## Keywords

None.

## Examples

If the variable A contains the string "IBM is fun", the substring "IBM" can be overwritten with the string "IDL" by entering:

```
STRPUT, A, 'IDL', 0
```

The following commands demonstrate the clipping of output that extends past the end of the destination string:

```
STRPUT, A, 'FUNNY', 7
PRINT, A
```

IDL prints:

```
IDL is FUN
```

## Version History

Introduced: Original

## See Also

STRMID, STRPOS, STRTRIM

# STRSPLIT

The STRSPLIT function splits its input *String* argument into separate substrings, according to the specified delimiter or regular expression. By default, the position of the substrings is returned. The EXTRACT keyword can be used to cause STRSPLIT to return an array containing the substrings.

## Syntax

*Result* = STRSPLIT( *String* [, *Pattern*] [, COUNT=*variable*] [, ESCAPE=*string* | , /REGEX [, /FOLD_CASE]] [, /EXTRACT | , LENGTH=*variable*] [, /PRESERVE_NULL] )

## Return Value

Returns an array containing either the positions of the substrings or the substrings themselves (if the EXTRACT keyword is specified).

## Arguments

### String

A scalar string to be split into substrings.

### Pattern

Pattern can contain one of two types of information:

- A string containing the character codes that are considered to be separators. In this case, IDL performs a simple string search for those characters. This method is simple and fast.
- A regular expression, as implemented by the STREGEX function, which is used by IDL to match the separators. This method is slower and more complex, but can handle extremely complicated input strings.

*Pattern* is an optional argument. If it is not specified, STRSPLIT defaults to splitting on spans of whitespace (space or tab characters) in *String*.

# Keywords

## COUNT

Set this keyword to a named variable that will contain the number of matched substrings returned by STRSPLIT. This value will be 0 if either of the *String* or *Pattern* arguments is null. Otherwise, it will cointain the number of elements in the *Result* array.

## ESCAPE

When doing simple pattern matching, the ESCAPE keyword can be used to specify any characters that should be considered to be “escape” characters. Preceding any character with an escape character prevents STRSPLIT from treating it as a separator character even if it is found in *Pattern*.

Note that if the EXTRACT keyword is set, STRSPLIT will automatically remove the escape characters from the resulting substrings. If EXTRACT is not specified, STRSPLIT cannot perform this editing, and the returned position and offsets will include the escape characters.

For example:

```
print, STRSPLIT('a\,b', ',', ESCAPE='\', /EXTRACT)
```

IDL prints:

```
a,b
```

ESCAPE cannot be specified with the FOLD_CASE or REGEX keywords.

## EXTRACT

By default, STRSPLIT returns an array of character offsets into *String* that indicate where the substrings are located. These offsets, along with the lengths available from the LENGTH keyword can be used later with STRMID to extract the substrings. Set EXTRACT to bypass this step, and cause STRSPLIT to return the substrings. EXTRACT cannot be specified with the LENGTH keyword.

## FOLD_CASE

Indicates that the regular expression matching should be done in a case-insensitive fashion. FOLD_CASE can only be specified if the REGEX keyword is set, and cannot be used with the ESCAPE keyword.

### LENGTH

Set this keyword to a named variable to receive the lengths of the substrings. Together with this result of this function, LENGTH can be used with the STRMID function to extract the matched substrings. The LENGTH keyword cannot be used with the EXTRACT keyword.

### PRESERVE_NULL

Normally, STRSPLIT will not return null length substrings unless there are no non-null values to report, in which case STRSPLIT will return a single null string. Set PRESERVE_NULL to cause all null substrings to be returned.

### REGEX

For complex splitting tasks, the REGEX keyword can be specified. In this case, *Pattern* is taken to be a regular expression to be matched against *String* to locate the separators. If REGEX is specified and *Pattern* is not, the default *Pattern* is the regular expression:

```
'[ ' + STRING(9B) + ']+'
```

which means “any series of one or more space or tab characters” (9B is the byte value of the ASCII TAB character).

Note that the default *Pattern* contains a space after the [ character.

The REGEX keyword cannot be used with the ESCAPE keyword.

**Note**

You must call the STRSPLIT procedure with the /REGEX keyword when the target string is more than one character.

## Examples

### Example 1

To split a string on spans of whitespace and replace them with hyphens:

```
Str = 'STRSPLIT chops up strings.'
print, STRJOIN(STRSPLIT(Str, /EXTRACT), '-')
```

IDL prints:

```
STRSPLIT-chops-up-strings.
```

## Example 2

As an example of a more complex splitting task that can be handled with the simple character-matching mode of STRSPLIT, consider a sentence describing different colored ampersand characters. For unknown reasons, the author used commas to separate all the words, and used ampersands or backslashes to escape the commas that actually appear in the sentence (which therefore should not be treated as separators). The unprocessed string looks like:

```
Str = 'There,was,a,red,&&&,,a,yellow,&&\,,and,a,blue,\&.'
```

We use STRSPLIT to break this line apart, and STRJOIN to reassemble it as a standard blank-separated sentence:

```
S = STRSPLIT(Str, ',', ESCAPE='&\', /EXTRACT)
PRINT, STRJOIN(S, ' ')
```

IDL prints:

```
There was a red &, a yellow &, and a blue &.
```

## Example 3

Strings separated by multi-character delimiters cannot be split using the simple character matching mode of STRSPLIT. Such delimiters require the use of a regular expression. For instance, consider splitting the following string on double ampersand boundaries.

```
str = ‘red&&blue&&yellow&&odds&ends’
```

The desired result of such splitting would be four strings, with the values ‘red’, ‘blue’, ‘yellow’, and ‘odds&ends’. You might be tempted to use STRSPLIT as follows:

```
PRINT, STRSPLIT(str,’&&’,/EXTRACT)
```

which causes IDL to print:

```
red blue yellow odds ends
```

IDL split the string on single ampersand boundaries, yielding 5 strings instead of the desired 4. When using the simple character matching mode of STRSPLIT, the characters in the Pattern argument specify a set of possible single character delimiters. The order of these characters is unimportant, and specifying a character more than once has no effect (the extras are ignored).

To properly split the above string using a regular expression:

```
print, strsplit(str,’&&’,/EXTRACT, /REGEX)
```

producing the desired IDL output:

```
red blue yellow odds&ends
```

## Example 4

Finally, suppose you had a complicated string, in which every token was preceded by the count of characters in that token, with the count enclosed in angle brackets:

```
str = '<4>What<1>a<7>tangled<3>web<2>we<6>weave.'
```

This is too complex to handle with simple character matching, but can be easily handled using the regular expression '<[0-9]+>' to match the separators. This regular expression can be read as “an opening angle bracket, followed by one or more

numeric characters between 0 and 9, followed by a closing angle bracket.” The STRJOIN function is used to glue the resulting substrings back together:

```
S = STRSPLIT(str,'<[0-9]+>',/EXTRACT,/REGEX)
PRINT, STRJOIN(S, ' ')
```

IDL prints:

```
What a tangled web we weave.
```

## Version History

Introduced: 5.3

## See Also

STRCMP, STRJOIN, STRMATCH, STREGEX, STRMID, STRPOS

# STRTRIM

The STRTRIM function removes leading and/or trailing blank from the input *String*.

## Syntax

*Result* = STRTRIM( *String* [, *Flag*] )

## Return Value

Returns a copy of string with the specified blank spaces removed.

## Arguments

### String

The string to have leading and/or trailing blanks removed. If this argument is not a string, it is converted using IDL's default formatting rules. If it is an array, the result is an array with the same structure where each element contains a trimmed copy of the corresponding element of *String*.

### Flag

A value that controls the action of STRTRIM. If *Flag* is zero or not present, trailing blanks are removed. Leading blanks are removed if it is equal to 1. Both are removed if it is equal to 2.

## Examples

Converting variables to string type often results in undesirable leading blanks. For example, the following command converts the integer 56 to string type:

```
C = STRING(56)
```

Entering the command:

```
HELP, C
```

IDL prints:

```
C         STRING = '      56'
```

which shows that there are six leading spaces before the characters 5 and 6. To remove these leading blanks, enter the command:

```
C = STRTRIM(C, 1)
```

To confirm that the blanks were removed, enter:

```
HELP, C
```

IDL prints:

```
C         STRING = '56'
```

STRMID, STRPOS, STRPUT, STRSPLIT

# STRUCT_ASSIGN

The IDL “=” operator is unable to assign a structure value to a structure of a different type. The STRUCT_ASSIGN procedure performs “relaxed structure assignment,” which is a field-by-field copy of a structure to another structure. Fields are copied according to the following rules:

1. Any fields found in the destination structure that are not found in the source structure are “zeroed” (set to zero, the empty string, or a null pointer or object reference depending on the type of field).
2. Any fields in the source structure that are not found in the destination structure are quietly ignored.
3. Any fields that are found in both the source and destination structures are copied one at a time. If necessary, type conversion is done to make their types agree. If a field in the source structure has fewer data elements than the corresponding field in the destination structure, then the “extra” elements in the field in the destination structure are zeroed. If a field in the source structure has more elements than the corresponding field in the destination structure, the extra elements are quietly ignored.

Relaxed structure assignment is especially useful when restoring structures from disk files into an environment where the structure definition has changed. See the description o f the RELAXED_STRUCTURE_ASSIGNMENT keyword to the RESTORE procedure for additional details. “Relaxed Structure Assignment” in Chapter 7 of the *Building IDL Applications* manual provides a more in-depth discussion of the structure-definition process.

## Syntax

STRUCT_ASSIGN, *Source*, *Destination* [, /NOZERO] [, /VERBOSE]

## Arguments

### Source

A named variable or element of an array containing a structure, the contents of which will be assigned to the structure specified by the *Destination* argument. *Source* can be an object reference if STRUCT_ASSIGN is called inside an object method.

### Destination

A named variable containing a structure into which the contents of the structure specified by the *Source* argument will be inserted. *Destination* can be an object reference if STRUCT_ASSIGN is called inside an object method.

## Keywords

### NOZERO

Normally, any fields found in the destination structure that are not found in the source structure are zeroed. Set NOZERO to prevent this action and leave the original contents of such fields unchanged.

### VERBOSE

Set this keyword to cause STRUCT_ASSIGN to issue informational messages about any incompatibilities that prevent data from being copied.

## Examples

The following example creates two anonymous structures, then uses STRUCT_ASSIGN to insert the contents of the first into the second:

```
source = { a:FINDGEN(4), b:12 }
dest = { a:INDGEN(2), c:20 }
STRUCT_ASSIGN, /VERBOSE, source, dest
```

IDL prints:

```
% STRUCT_ASSIGN: <Anonymous> tag A is longer than destination.
                 The end will be clipped.
% STRUCT_ASSIGN: Destination lacks <Anonymous> tag B. Not copied.
```

After assignment, `dest` contains a two-element integer array [0, 1] in its field A and the integer 0 in its field C. Since `dest` does not have a field B, field B from `source` is not copied.

## Version History

Introduced: 5.1

# STRUCT_HIDE

The IDL HELP procedure displays information on all known structures or object classes when used with the STRUCTURES or OBJECTS keywords. Although this is usually the desired behavior, authors of large vertical applications or library routines may wish to prevent IDL from displaying information on structures or objects that are not part of their public interface, but which exist solely in support of the internal implementation. The STRUCT_HIDE procedure is used to mark such structures or objects as hidden. Items so marked are not displayed by `HELP, /STRUCTURE` unless the user sets the FULL keyword, but are otherwise unaltered.

**Note**

STRUCT_HIDE is primarily intended for use with named structures or objects. Although it can be safely used with anonymous structures, there is no visible benefit to doing so as anonymous structures are hidden by default.

**Tip**

Authors of objects will often place a call to STRUCT_HIDE in the _ _DEFINE procedure that defines the structure.

## Syntax

STRUCT_HIDE, $Arg_1$ [, $Arg_2$, ..., $Arg_n$]

## Arguments

### $Arg_1$, ..., $Arg_n$

If an argument is a variable of one of the following types, its underlying structure and/or object definition is marked as being hidden from the HELP procedure's default output:

- Structure
- Pointer that refers to a heap variable of structure type
- Object Reference

Any arguments that are not one of these types are quietly ignored. No change is made to the value of any argument.

## Keywords

None

## Examples

This example shows how a structure can be hidden if an application designer doesn't want end-users to be able to see it, but variables are not hidden. To create a named structure called `bullwinkle` and prevent it from appearing in the HELP procedure's default output, do the following.

```
; Define a variable containing the named structure:
tmp = { bullwinkle, moose:1, squirrel:0 }
; IDL returns BULLWINKLE in addition to the other system variables.
HELP, /STRUCTURE, /BRIEF
; Next, specifically hide the structure using
; the STRUCT_HIDE procedure.
STRUCT_HIDE, tmp
; This time IDL returns the system variables but
; not the BULLWINKLE structure.
HELP, /STRUCTURE, /BRIEF
; IDL returns the variable tmp showing that it is
; a named structure called BULLWINKLE.
HELP, tmp
```

## Version History

Introduced: 5.3

COMPILE_OPT

# STRUPCASE

The STRUPCASE function returns a copy of *String* converted to upper case. Only lowercase characters are modified—uppercase and non-alphabetic characters are copied without change.

## Syntax

*Result* = STRUPCASE(*String*)

## Return Value

Returns a string composed of uppercase characters.

## Arguments

### String

The string to be converted. If this argument is not a string, it is converted using IDL's default formatting rules. If it is an array, the result is an array with the same structure where each element contains an uppercase copy of the corresponding element of *String*.

## Keywords

None.

## Examples

To print an uppercase version of the string "IDL is fun", enter:

```
PRINT, STRUPCASE('IDL is fun')
```

IDL prints:

```
IDL IS FUN
```

## Version History

Introduced: Original

## See Also

STRLOWCASE

# SURFACE

The SURFACE procedure draws a wire-mesh representation of a two-dimensional array projected into two dimensions, with hidden lines removed.

### Restrictions

If the *(X, Y)* grid is not regular or nearly regular, errors in hidden line removal occur. The TRIGRID and TRIANGULATE routines can be used to interpolate irregularly-gridded data points to a regular grid before plotting.

If the T3D keyword is set, the 3-D to 2-D transformation matrix contained in !P.T must project the Z axis to a line parallel to the device Y axis, or errors will occur.

The surface lines may blend together when drawing large arrays, especially on low or medium resolution displays. Use the REBIN or CONGRID procedure to resample the array to a lower resolution before plotting.

## Syntax

SURFACE, *Z* [, *X*, *Y*] [, AX=*degrees*] [, AZ=*degrees*] [, BOTTOM=*index*] [, /HORIZONTAL] [, /LEGO] [, /LOWER_ONLY | , /UPPER_ONLY] [, MAX_VALUE=*value*] [, MIN_VALUE=*value*] [, /SAVE] [, SHADES=*array*] [, SKIRT=*value*] [, /XLOG] [, /YLOG] [, ZAXIS={1 | 2 | 3 | 4}] [, /ZLOG]

**Graphics Keywords:** Accepts all graphics keywords accepted by PLOT except for: PSYM, SYMSIZE. See “Graphics Keywords Accepted” on page 1938.

## Arguments

### Z

The two-dimensional array to be displayed. If *X* and *Y* are provided, the surface is plotted as a function of the (*X*, *Y*) locations specified by their contents. Otherwise, the surface is generated as a function of the array index of each element of *Z*.

This argument is converted to double-precision floating-point before plotting. Plots created with SURFACE are limited to the range and precision of double-precision floating-point values.

### X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of *X* specifies the X coordinate for a column of *Z*

(e.g., `X[0]` specifies the X coordinate for `Z[0,*]`). If *X* is a two-dimensional array, each element of *X* specifies the X coordinate of the corresponding point in *Z* ($X_{ij}$ specifies the X coordinate for $Z_{ij}$).

This argument is converted to double-precision floating-point before plotting.

### Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of *Y* specifies the Y coordinate for a row of *Z* (e.g., `Y[0]` specifies the Y coordinate for `Z[*,0]`). If *Y* is a two-dimensional array, each element of *Y* specifies the Y coordinate of the corresponding point in *Z* ($Y_{ij}$ specifies the Y coordinate for $Z_{ij}$).

This argument is converted to double-precision floating-point before plotting.

## Keywords

### AX

This keyword specifies the angle of rotation, about the X axis, in degrees towards the viewer. This keyword is effective only if !P.T3D is not set. If !P.T3D is set, the three-dimensional to two-dimensional transformation used by SURFACE is taken from the 4 by 4 array !P.T.

The surface represented by the two-dimensional array is first rotated, AZ (see below) degrees about the Z axis, then by AX degrees about the X axis, tilting the surface towards the viewer (AX > 0), or away from the viewer.

The AX and AZ keyword parameters default to +30 degrees if omitted and !P.T3D is 0.

The three-dimensional to two-dimensional transformation represented by AX and AZ, can be saved in !P.T by including the SAVE keyword.

### AZ

This keyword specifies the counterclockwise angle of rotation about the Z axis. This keyword is effective only if !P.T3D is not set. The order of rotation is AZ first, then AX.

### BOTTOM

The color index used to draw the bottom surface. If not specified, the bottom is drawn with the same color as the top.

## HORIZONTAL

A keyword flag which if set causes SURFACE to only draw lines across the plot perpendicular to the line of sight. The default is for SURFACE to draw both across the plot and from front to back.

## LEGO

Set this keyword to produce stacked histogram-style plots. Each data value is rendered as a box covering the XY extent of the cell and with a height proportional to the Z value.

If the *X* and *Y* arguments are specified, only $N_x$-1 columns and $N_y$-1 rows are drawn. (This means that the last row and column of array data are not displayed.) The rectangular area covered by *Z*[*i, j*] is given by *X*[*i*], *X*[*i*+1], *Y*[*j*], and *Y*[*j*+1].

## LOWER_ONLY

Set this keyword to draw only the lower surface of the object. By default, both surfaces are drawn.

## MAX_VALUE

The maximum value to be plotted. If this keyword is present, data values greater than the value of MAX_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special Floating-Point Values" in Chapter 18 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## MIN_VALUE

The minimum value to be plotted. If this keyword is present, data values less than the value of MIN_VALUE are treated as missing and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. (See "Special Floating-Point Values" in Chapter 18 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## SAVE

Set this keyword to save the 3-D to 2-D transformation matrix established by SURFACE in the system variable field !P.T. Use this keyword when combining the output of SURFACE with additional output from other routines in the same plot.

When used with AXIS, the SAVE keyword parameter saves the scaling parameters established by the call in the appropriate axis system variable, !X, !Y, or !Z. This causes subsequent overplots to be scaled to the new axis.

For example, to display a two-dimensional array using SURFACE, and to then superimpose contours over the surface (this example assumes that !P.T3D is zero, its default value.), enter the following commands:

```
; Make a surface plot and save the transformation:
SURFACE, Z, /SAVE

; Make contours, don't erase, use the 3-D to 2-D transform placed
; in !P.T by SURFACE:
CONTOUR, Z, /NOERASE, /T3D
```

To display a surface and to then display a flat contour plot, registered above the surface:

```
; Make the surface, save transform:
SURFACE, Z, /SAVE

; Now display a flat contour plot, at the maximum Z value
; (normalized coordinates):
CONTOUR, Z, /NOERASE, /T3D, ZVALUE=1.0
```

You can display the contour plot below the surface with by using a ZVALUE of 0.0.

## SHADES

This keyword allows user-specified coloring of the mesh surfaces. Set this keyword to an array that specifies the color index of the lines emanating from each data point toward the top and right.

**Warning**

When using the SHADES keyword on True Color devices, we recommend that decomposed color support be turned off, by setting `DEVICE, DECOMPOSED=0`. See "DEVICE" on page 488 and "DECOMPOSED" on page 3795.

## SKIRT

This keyword represents a Z-value at which to draw a skirt around the array. The Z value is expressed in data units. The default is no skirt.

If the skirt is drawn, each point on the four edges of the surface is connected to a point on the skirt which has the given Z value, and the same X and Y values as the edge point. In addition, each point on the skirt is connected to its neighbor.

### UPPER_ONLY

Set this keyword to draw only the upper surface of the object. By default, both surfaces are drawn.

### XLOG

Set this keyword to specify a logarithmic X axis.

### YLOG

Set this keyword to specify a logarithmic Y axis.

### ZAXIS

This keyword specifies the placement of the Z axis for the SURFACE plot.

By default, SURFACE draws the Z axis at the upper left corner of the axis box. To suppress the Z axis, use `ZAXIS=-1` in the call. The position of the Z axis is determined from the value of ZAXIS as follows: 1 = lower right, 2 = lower left, 3 = upper left, and 4 = upper right.

### ZLOG

Set this keyword to specify a logarithmic Z axis.

### Graphics Keywords Accepted

See Appendix B, “Graphics Keywords”, for the description of graphics and plotting keywords not listed above. BACKGROUND, CHARSIZE, CHARTHICK, CLIP, COLOR, DATA, DEVICE, FONT, LINESTYLE, NOCLIP, NODATA, NOERASE, NORMAL, POSITION, SUBTITLE, T3D, THICK, TICKLEN, TITLE, [XYZ]CHARSIZE, [XYZ]GRIDSTYLE, [XYZ]MARGIN, [XYZ]MINOR, [XYZ]RANGE, [XYZ]STYLE, [XYZ]THICK, [XYZ]TICKFORMAT, [XYZ]TICKINTERVAL, [XYZ]TICKLAYOUT, [XYZ]TICKLEN, [XYZ]TICKNAME, [XYZ]TICKS, [XYZ]TICKUNITS, [XYZ]TICKV, [XYZ]TICK_GET, [XYZ]TITLE, ZVALUE.

## Examples

```
; Create a simple dataset to display:
D = DIST(30)

; Plot a simple wire-mesh surface representation of D:
SURFACE, D
```

```
; Create a wire-mesh plot of D with a title and a "skirt" around
; the edges of the dataset at Z=0:
SURFACE, D, SKIRT=0.0, TITLE = 'Surface Plot', CHARSIZE = 2
```

## Version History

Introduced: Original

CONTOUR, ISURFACE, SHADE_SURF

# SURFR

The SURFR procedure sets up 3-D transformations. This procedure duplicates the rotation, translation, and scaling features of the SURFACE routine, but does not display any data. The resulting transformations are stored in the !P.T system variable.

This routine is written in the IDL language. Its source code can be found in the file `surfr.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

SURFR [, AX=*degrees*] [, AZ=*degrees*]

## Arguments

None.

## Keywords

### AX

Angle of rotation about the X axis. The default is 30 degrees.

### AZ

Angle of rotation about the Z axis. The default is 30 degrees.

## Version History

Introduced: Original

SCALE3, SCALE3D, T3D

# SVDC

The SVDC procedure computes the Singular Value Decomposition (SVD) of a square (*n* x *n*) or non-square (*n* x *m*) array as the product of orthogonal and diagonal arrays. SVD is a very powerful tool for the solution of linear systems, and is often used when a solution cannot be determined by other numerical algorithms.

The SVD of an (*n* x *m*) non-square array *A* is computed as the product of an (*n* x *m*) column orthogonal array *U*, an (*n* x *n*) diagonal array *SV*, composed of the singular values, and the transpose of an (*n* x *n*) orthogonal array V: A = U SV $V^T$

SVDC is based on the routine `svdcmp` described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

**Note**

If you are working with complex inputs, instead use the LA_SVD procedure.

## Syntax

SVDC, *A*, *W*, *U*, *V* [, /COLUMN] [, /DOUBLE] [, ITMAX=*value*]

## Arguments

### A

The square (*n* x *n*) or non-square (*n* x *m*) single- or double-precision floating-point array to decompose.

### W

On output, *W* is an *n*-element output vector containing the “singular values.”

### U

On output, *U* is an *n*-column, *m*-row orthogonal array used in the decomposition of *A*.

### V

On output, *V* is an *n*-column, *n*-row orthogonal array used in the decomposition of *A*.

# Keywords

## COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

## DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## ITMAX

Set this keyword to specify the maximum number of iterations. The default value is 30.

# Examples

To find the singular values of an array A:

```
; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
     [1.5, 3.3, -0.5, 2.0], $
     [3.1, 0.7,  2.2, 0.0], $
     [0.0, 0.3, -2.0, 5.3], $
     [2.1, 1.0,  4.3, 2.2], $
     [0.0, 5.5,  3.8, 0.2]]

; Compute the Singular Value Decomposition:
SVDC, A, W, U, V

; Print the singular values:
PRINT, W
```

IDL prints:

```
8.81973      2.65502      4.30598      6.84484
```

To verify the decomposition, use the relationship A = U ## SV ## TRANSPOSE(V), where SV is a diagonal array created from the output vector W:

```
sv = FLTARR(4, 4)
FOR K = 0, 3 DO sv[K,K] = W[K]
result = U ## sv ## TRANSPOSE(V)
PRINT, result
```

IDL prints:

```
      1.00000      2.00000     -1.00000      2.50000
      1.50000      3.30000    -0.500001      2.00000
      3.10000     0.700000      2.20000      0.00000
  2.23517e-08     0.300000     -2.00000      5.30000
      2.10000     0.999999      4.30000      2.20000
 -3.91155e-07      5.50000      3.80000     0.200000
```

This is the input array, to within machine precision.

## Version History

# SVDFIT

The SVDFIT function performs a least squares fit with optional error estimates. Either a user-supplied function written in the IDL language or a built-in polynomial can be used to fit the data.

SVDFIT is based on the routine `svdfit` described in section 15.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = SVDFIT( *X*, *Y* [, *M*] [, A=*vector*] [, CHISQ=*variable*] [, COVAR=*variable*] [, /DOUBLE] [, FUNCTION_NAME=*string*] [, /LEGENDRE] [, MEASURE_ERRORS=*vector*] [, SIGMA=*variable*] [, SING_VALUES=*variable*] [, SINGULAR=*variable*] [, STATUS=*variable*] [, TOL=*value*] [, VARIANCE=*variable*] [, YFIT=*variable*] )

## Return Value

Returns a vector of coefficients.

## Arguments

### X

An n-element vector of independent variables.

### Y

A vector of dependent variables, the same length as *X*.

### M

The number of coefficients in the fitting function. For polynomials, *M* is equal to the degree of the polynomial + 1. If the *M* argument is not specified, you must supply initial coefficient estimates using the A keyword. In this case, *M* is set equal to the number of elements of the array specified by the A keyword.

# Keywords

## A

This keyword is both an input and output keyword. Set this keyword equal to a variable containing a vector of initial estimates for the fitted function parameters. On exit, SVDFIT returns in this variable a vector of coefficients that are improvements of the initial estimates. If A is supplied, the *M* argument will be set equal to the number of elements in the vector specified by A.

## CHISQ

Set this keyword equal to a named variable that will contain the value of the chi-sqaure goodness-of-fit.

## COVAR

Set this keyword equal to a named variable that will contain the covariance matrix of the fitted coefficients.

**Note**

The COVAR matrix depends only upon the independent variable X and (optionally) the MEASURE_ERRORS. The values do not depend upon Y. See section 15.4 of *Numerical Recipes in C* (Second Edition) for details.

## DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## FUNCTION_NAME

Set this keyword equal to a string containing the name of a user-supplied IDL basis function with *M* coefficients. If this keyword is omitted, and the LEGENDRE keyword is not set, IDL assumes that the IDL procedure SVDFUNCT, found in the file `svdfunct.pro`, located in the `lib` subdirectory of the IDL distribution, is to be used. SVDFUNCT uses the basis functions for the fitting polynomial:

$$y = \sum_{i=0}^{M} A(i)x^{i}$$

The function to be fit must be written as an IDL function and compiled prior to calling SVDFIT. The function must accept values of *X* (a scalar), and *M* (a scalar). It must return an *M*-element vector containing the basis functions.

See the "Examples" section below for an example function.

## LEGENDRE

Set this keyword to use Legendre polynomials instead of the function specified by the FUNCTION_NAME keyword. If the LEGENDRE keyword is set, the IDL uses the function SVDLEG found in the file `svdleg.pro`, located in the `lib` subdirectory of the IDL distribution.

## MEASURE_ERRORS

Set this keyword to a vector containing standard measurement errors for each point *Y*[*i*]. This vector must be the same length as *X* and *Y*.

**Note**

For Gaussian errors (e.g., instrumental uncertainties), MEASURE_ERRORS should be set to the standard deviations of each point in *Y*. For Poisson or statistical weighting, MEASURE_ERRORS should be set to SQRT(*Y*).

## SIGMA

Set this keyword to a named variable that will contain the 1-sigma uncertainty estimates for the returned parameters.

**Note**

If MEASURE_ERRORS is omitted, then you are assuming that the polynomial (or your user-supplied model) is the correct model for your data, and therefore, no independent goodness-of-fit test is possible. In this case, the values returned in SIGMA are multiplied by SQRT(CHISQ/(*N*–*M*)), where *N* is the number of points in *X*, and *M* is the number of coefficients. See section 15.2 of *Numerical Recipes in C* (Second Edition) for details.

## SING_VALUES

Set this keyword to a named variable in which to return the singular values from the SVD. Singular values which have been removed will be set to zero.

## SINGULAR

Set this keyword equal to a named variable that will contain the number of singular values returned. This value should be 0. If not, the basis functions do not accurately characterize the data.

## STATUS

Set this keyword to a named variable that will contain the status of the computation. Possible values are:

- STATUS = 0: The computation was successful.
- STATUS > 0: Singular values were found and were removed. STATUS contains the number of singular values.

**Note**

If STATUS is not specified, any error messages will be output to the screen.

## TOL

Set this keyword to the tolerance used when removing singular values. The default is $10^{-5}$ for single precision, and $2x10^{-12}$ for double precision (these defaults are approximately 100 and 10000 times the machine precisions for single and double precision, respectively).

Setting TOL to a larger value may remove coefficients that do not contribute to the solution, which may reduce the errors on the remaining coefficients.

## VARIANCE

Set this keyword equal to a named variable that will contain the variance (sigma squared) of each coefficient *M*.

## WEIGHTS

*The WEIGHTS keyword is obsolete and has been replaced by the MEASURE_ERRORS keyword. Code that uses the WEIGHTS keyword will continue to work as before, but new code should use the MEASURE_ERRORS keyword. Note that the definition of the MEASURE_ERRORS keyword is not the same as the WEIGHTS keyword. Using the WEIGHTS keyword, 1/WEIGHTS[i] represents the measurement error for each point Y[i]. Using the MEASURE_ERRORS keyword, the measurement error is represented as simply MEASURE_ERRORS[i].*

### YFIT

Set this keyword equal to a named variable that will contain the vector of calculated *Y* values.

## Examples

This example fits a function of the following form:

$$F(x) = A(0) + A(1)\sin\frac{(2x)}{x} + A(2)\cos(4x)^2$$

First, create the function in IDL, then create a procedure to perform the fit. Create the following file called `example_svdfit.pro`:

```
PRO example_svdfit

; Provide an array of coefficients:
C = [7.77, 8.88, -9.99]
X = FINDGEN(100)/15.0 + 0.1
Y = C[0] + C[1] * SIN(2*X)/X + C[2] * COS(4.*X)^2.

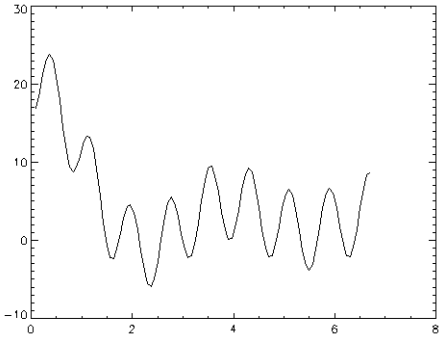
; Set uncertainties to 5%:
measure_errors = 0.05 * Y

; Provide an initial guess:
A=[1,1,1]
result_a = SVDFIT(X, Y, A=A, MEASURE_ERRORS=measure_errors, $
   FUNCTION_NAME='myfunct', SIGMA=SIGMA, YFIT=YFIT)

; Plot the results:
PLOT, X, YFIT
FOR I = 0, N_ELEMENTS(A)-1 DO $
   PRINT, I, result_a[I], SIGMA[I], C[I],$
   FORMAT = $
   '(" result_a ( ",I1," ) = ",F7.4," +- ",F7.4," VS. ",F7.4)'
END

FUNCTION myfunct, X ,M
   RETURN,[ [1.0], [SIN(2*X)/X], [COS(4.*X)^2.] ]
END
```

Place the file `example_svdfit.pro` in a directory in the IDL search path, and enter `example_svdfit` at the command prompt to create the plot.



In addition to creating the above plot, IDL prints:

```
result_a ( 0 ) =  7.7700 +-  0.0390 VS.  7.7700
result_a ( 1 ) =  8.8800 +-  0.0468 VS.  8.8800
result_a ( 2 ) = -9.9900 +-  0.0506 VS. -9.9900
```

# SVSOL

The SVSOL function uses “back-substitution” to solve a set of simultaneous linear equations Ax = b, given the *U*, *W*, and *V* arrays returned by the SVDC procedure. None of the input arguments are modified, making it possible to call SVSOL multiple times with different right hand vectors, *B*.

SVSOL is based on the routine `svbksb` described in section 2.6 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = SVSOL( *U*, *W*, *V*, *B* [, /COLUMN] [, /DOUBLE] )

## Return Value

Returns the solution to the linear system using decomposition and back substitution.

## Arguments

### U

An *n*-column, *m*-row orthogonal array used in the decomposition of *A*. Normally, *U* is returned from the SVDC procedure.

### W

An *n*-element vector containing “singular values.” Normally, *W* is returned from the SVDC procedure. Small values (close to machine floating-point precision) should be set to zero prior to calling SVSOL.

### V

An *n*-column, *n*-row orthogonal array used in the decomposition of *A*. Normally, *V* is returned from the SVDC procedure.

### B

An *m*-element vector containing the right hand side of the linear system Ax = b.

# Keywords

## COLUMN

Set this keyword if the input arrays *U* and *V* are in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

## DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

# Examples

To solve the linear system Ax = b using Singular-value decomposition and back substitution, begin with an array A which serves as the coefficient array:

```
; Define the array A:
A = [[1.0, 2.0, -1.0, 2.5], $
     [1.5, 3.3, -0.5, 2.0], $
     [3.1, 0.7,  2.2, 0.0], $
     [0.0, 0.3, -2.0, 5.3], $
     [2.1, 1.0,  4.3, 2.2], $
     [0.0, 5.5,  3.8, 0.2]]

; Define the right-hand side vector B:
B = [0.0, 1.0, 5.3, -2.0, 6.3, 3.8]

; Decompose A:
SVDC, A, W, U, V

; Compute the solution and print the result:
PRINT, SVSOL(U, W, V, B)
```

IDL prints:

```
1.00095   0.00881170     0.984176   -0.0100954
```

This is the correct solution.

# SWAP_ENDIAN

The SWAP_ENDIAN function reverses the byte ordering of arbitrary scalars, arrays or structures. It can make “big endian” number “little endian” and vice-versa.

**Note**

The BYTEORDER procedure can be used to reverse the byte ordering of *scalars and arrays* (SWAP_ENDIAN also allows structures).

This routine is written in the IDL language. Its source code can be found in the file `swap_endian.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = SWAP_ENDIAN(*Variable* [, /SWAP_IF_BIG_ENDIAN] [, /SWAP_IF_LITTLE_ENDIAN])

## Return Value

SWAP_ENDIAN returns values of the same type and structure as the input value, with the pertinent bytes reversed.

## Arguments

### Variable

The named variable—scalar, array, or structure—to be swapped.

## Keywords

### SWAP_IF_BIG_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the SWAP_ENDIAN request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

### SWAP_IF_LITTLE_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the SWAP_ENDIAN

request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

## Examples

```
; Reverse the byte order of A:
A = SWAP_ENDIAN(A)
```

## Version History

Introduced: Pre 4.0

SWAP_IF_BIG_ENDIAN and SWAP_IF_LITTLE_ENDIAN keywords added: 5.6

BYTEORDER, SWAP_ENDIAN_INPLACE

# SWAP_ENDIAN_INPLACE

The SWAP_ENDIAN_INPLACE procedure reverses the byte ordering of arbitrary scalars, arrays or structures. It can make “big endian” number “little endian” and vice-versa.

**Note**

The BYTEORDER procedure can be used to reverse the byte ordering of *scalars and arrays* (SWAP_ENDIAN_INPLACE also allows structures).

SWAP_ENDIAN_INPLACE differs from the SWAP_ENDIAN function in that it alters the input data in place rather than making a copy as does SWAP_ENDIAN. SWAP_ENDIAN_INPLACE can therefore be more efficient, if a copy of the data is not needed. The pertinent bytes in the input variable are reversed.

This routine is written in the IDL language. Its source code can be found in the file `swap_endian_inplace.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

SWAP_ENDIAN_INPLACE, *Variable* [, /SWAP_IF_BIG_ENDIAN] [, /SWAP_IF_LITTLE_ENDIAN]

## Arguments

### Variable

The named variable—scalar, array, or structure—to be swapped.

## Keywords

### SWAP_IF_BIG_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “big endian” byte ordering. On little endian machines, the SWAP_ENDIAN_INPLACE request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

### SWAP_IF_LITTLE_ENDIAN

If this keyword is set, the swap request will only be performed if the platform running IDL uses “little endian” byte ordering. On big endian machines, the SWAP_ENDIAN_INPLACE request quietly returns without doing anything. Note that this keyword does not refer to the byte ordering of the input data, but to the computer hardware.

## Examples

Reverse the byte order of A:

```
SWAP_ENDIAN_INPLACE, A
```

## Version History

Introduced: 5.6

BYTEORDER, SWAP_ENDIAN

# SWITCH

The SWITCH statement is used to select one statement for execution from multiple choices, depending upon the value of the expression following the word SWITCH.

Each statement that is part of a SWITCH statement is preceded by an expression that is compared to the value of the SWITCH expression. SWITCH executes by comparing the SWITCH expression with each selector expression in the order written. If a match is found, program execution jumps to that statement and execution continues from that point. Whereas CASE executes at most one statement within the CASE block, SWITCH executes the first matching statement and any following statements in the SWITCH block. Once a match is found in the SWITCH block, execution falls through to any remaining statements. For this reason, the BREAK statement is commonly used within SWITCH statements to force an immediate exit from the SWITCH block.

The ELSE clause of the SWITCH statement is optional. If included, it matches any selector expression, causing its code to be executed. For this reason, it is usually written as the last clause in the switch statement. The ELSE statement is executed only if none of the preceding statement expressions match. If an ELSE clause is not included and none of the values match the selector, program execution continues immediately below the SWITCH without executing any of the SWITCH statements.

SWITCH is similar to the CASE statement. For more information on using SWITCH and other IDL program control statements, as well as the differences between SWITCH and CASE, see Chapter 12, “Program Control” in the *Building IDL Applications* manual.

## Syntax

SWITCH *expression* OF

*expression*: *statement*

...

*expression*: *statement*

ELSE: *statement*

ENDSWITCH

## Examples

This example illustrates how, unlike CASE, SWITCH executes the first matching statement and any following statements in the SWITCH block:

```
x=2

SWITCH x OF
   1: PRINT, 'one'
   2: PRINT, 'two'
   3: PRINT, 'three'
   4: PRINT, 'four'
ENDSWITCH
```

IDL Prints:

```
two
three
four
```

## Version History

Introduced: 5.4

CASE

# SYSTIME

The SYSTIME function returns the current time as either a date/time string, as the number of seconds elapsed since 1 January 1970, or as a Julian date/time value.

## Syntax

*String* = SYSTIME( [0 [, *ElaspedSeconds*]] [, /UTC] )

or

*Seconds* = SYSTIME( 1 | /SECONDS )

or

*Julian* = SYSTIME( /JULIAN [, /UTC] )

## Return Value

Returns the specified time.

## Arguments

### SecondsFlag

If *SecondsFlag* is present and nonzero, the number of seconds elapsed since 1 January 1970 UTC is returned as a double-precision, floating-point value.

Otherwise, if *SecondsFlag* is not present or zero, a scalar string containing the date/time is returned in standard 24-character system format as follows:

```
DOW MON DD HH:MM:SS YEAR
```

where DOW is the day of the week, MON is the month, DD is the day of the month, HH is the hour, MM is the minute, SS is the second, and YEAR is the year. By default, the date/time string is adjusted for the local time zone; use the UTC keyword to override this default.

**Note**

If the JULIAN or SECONDS keyword is set, the *SecondsFlag* argument is ignored.

### ElapsedSeconds

If the *SecondsFlag* argument is zero, the *ElapsedSeconds* argument may be set to the number of seconds past 1 January 1970 UTC. In this case, SYSTIME returns the

corresponding date/time string (rather than the string for the current time). The returned date/time string is adjusted for the local time zone, unless the UTC keyword is set. If this argument is present, the JULIAN keyword is not allowed.

# Keywords

## JULIAN

Set this keyword to specify that the current time is to be returned as a a double precision floating value containing the current Julian date/time. By default, the current time is adjusted for the local time zone; use the UTC keyword to override this default. This keyword is not allowed if the *ElapsedSeconds* argument is present.

**Note**

If the JULIAN keyword is set, a small offset is added to the returned Julian date to eliminate roundoff errors when calculating the day fraction from hours, minutes, and seconds. This offset is given by the larger of EPS and EPS*Julian, where Julian is the integer portion of the Julian date, and EPS is the EPS field from MACHAR. For typical Julian dates, this offset is approximately $6x10^{-10}$ (which corresponds to $5x10^{-5}$ seconds). This offset ensures that if the Julian date is converted back to hour, minute, and second, then the hour, minute, and second will have the same integer values as were originally input.

## SECONDS

Set this keyword to specify that the current time is to be returned as the number of seconds elapsed since 1 January 1970 UTC. This option is equivalent to setting the *SecondsFlag* argument to a non-zero value.

## UTC

Set this keyword to specify that the value returned by SYSTIME is to be returned in Universal Time Coordinated (UTC) rather than being adjusted for the current time zone. UTC time is defined as Greenwich Mean Time updated with leap seconds.

# Examples

Print today’s date as a string:

```
PRINT, SYSTIME()
```

Print today’s date as a string in UTC (rather than local time zone):

```
PRINT, SYSTIME(/UTC)
```

Print today's date as a Julian date/time value in UTC:

```
PRINT, SYSTIME(/JULIAN, /UTC), FORMAT='(f12.2)'
```

Compute the seconds elapsed since 1 January 1970 UTC:

```
seconds = SYSTIME(1) ; or seconds = SYSTIME(/SECONDS)
```

Verify that the seconds from the previous example are correct:

```
PRINT, SYSTIME(0, seconds)
```

Print the day of the week:

```
PRINT, STRMID(SYSTIME(0), 0, 3)
```

Compute the time required to perform a 16,384 point FFT:

```
T = SYSTIME(1)
A = FFT(FINDGEN(16384), -1)
PRINT, SYSTIME(1) - T, 'Seconds'
```

## Version History

CALDAT, CALENDAR, JULDAY, TIMEGEN

# T_CVF

The T_CVF function computes the cutoff value *V* in a Student's t distribution with *Df* degrees of freedom such that the probability that a random variable *X* is greater than *V* is equal to a user-supplied probability *P*.

**Note**

T_CVF computes the cutoff value using the one-tailed probability. The cutoff value for the two-tailed probability, which is the probability that the absolute value of *X* is greater than *V*), can be computed as T_CVF(*P*/2, *Df*).

This routine is written in the IDL language. Its source code can be found in the file `t_cvf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = T_CVF(*P, Df*)

## Return Value

Returns the cutoff value.

## Arguments

### P

A non-negative single- or double-precision floating-point scalar, in the interval [0.0, 1.0], that specifies the probability of occurrence or success.

### Df

A positive integer, single- or double-precision floating-point scalar that specifies the number of degrees of freedom of the Student's t distribution.

## Keywords

None.

## Examples

Use the following command to compute the cutoff value in a Student’s t distribution with five degrees of freedom such that the probability that a random variable X is greater than the cutoff value is 0.025.

```
result = T_CVF(0.025, 5)
PRINT, result
```

IDL prints:

```
2.57058
```

## Version History

Introduced: 4.0

## See Also

CHISQR_CVF, F_CVF, GAUSS_CVF, T_PDF

# T_PDF

The T_PDF function computes the probability *P* that, in a Student's t distribution with *Df* degrees of freedom, a random variable *X* is less than or equal to a user-specified cutoff value *V*.

**Note**

T_PDF computes the one-tailed probability. The two-tailed probability, which is the probability that the absolute value of *X* is less than or equal to *V*, can be computed as 1 - 2×(1 - T_PDF(*V, Df*)).

This routine is written in the IDL language. Its source code can be found in the file `t_pdf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = T_PDF(*V, Df*)

## Return Value

If both arguments are scalar, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of *V* and *Df*, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the input array.

If any of the arguments are double-precision, the result is double-precision, otherwise the result is single-precision.

## Arguments

### V

A scalar or array that specifies the cutoff value(s).

### Df

A scalar or array that specifies the number of degrees of freedom of the Student's t distribution.

## Keywords

None.

## Examples

Use the following command to compute the probability that a random variable X, from the Student's t distribution with 15 degrees of freedom, is less than or equal to 0.691:

```
PRINT, T_PDF(0.691, 15)
```

IDL prints:

```
0.749940
```

## Version History

Introduced: 4.0

BINOMIAL, CHISQR_PDF, F_PDF, GAUSS_PDF, T_CVF

# T3D

The T3D procedure implements three-dimensional transforms.

This routine accumulates one or more sequences of translation, scaling, rotation, perspective, and oblique transformations and stores the result in !P.T, the 3D transformation system variable. All the IDL graphic routines use this (4,4) matrix for output. Note that !P.T3D is *not* set, so for the transformations to have effect you must set !P.T3D = 1 (or set the T3D keyword in subsequent calls to graphics routines).

This procedure is based on that of Foley & Van Dam, *Fundamentals of Interactive Computer Graphics*, Chapter 8, “Viewing in Three Dimensions”. The matrix notation is reversed from the normal IDL sense, i.e., here, the first subscript is the column, the second is the row, in order to conform with this reference.

A right-handed system is used. Positive rotations are counterclockwise when looking from a positive axis position towards the origin.

This routine is written in the IDL language. Its source code can be found in the file `t3d.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

T3D [, *Array* | , /RESET] [, MATRIX=*variable*] [, OBLIQUE=*vector*]
[, PERSPECTIVE=*p*{eye at (0,0,*p*)}] [, ROTATE=*[x, y, z]*] [, SCALE=*[x, y, z]*]
[, TRANSLATE=*[x, y, z]*] [, /XYEXCH | , /XZEXCH | , /YZEXCH]

## Arguments

### Array

An optional 4 x 4 matrix used as the starting transformation. If *Array* is missing, the current !P.T transformation is used. *Array* is ignored if /RESET is set.

## Keywords

The transformation specified by each keyword is performed in the order of their descriptions below (e.g., if both TRANSLATE and SCALE are specified, the translation is done first).

## MATRIX

Set this keyword to a named variable that will contain the result. If this keyword is specified, !P.T is not modified.

## OBLIQUE

A two-element vector of oblique projection parameters. Points are projected onto the XY plane at Z=0 as follows:

```
x' = x + z(d * COS(a))
y' = y + z(d * SIN(a))
```

where OBLIQUE[0] = d and OBLIQUE[1] = a.

## PERSPECTIVE

Perspective transformation. This parameter is a scalar (p) that indicates the Z distance of the center of the projection. Objects are projected into the XY plane at Z=0, and the “eye” is at point (0,0,p).

## RESET

Set this keyword to reset the transformation to the default identity matrix.

## ROTATE

A three-element vector of the rotations, in DEGREES, about the X, Y, and Z axes. Rotations are performed in the order of X, Y, and then Z.

## SCALE

A three-element vector of scale factors for the X, Y, and Z axes.

## TRANSLATE

A three-element vector of the translations in the X, Y, and Z directions.

## XYEXCH

Set this keyword to exchange the X and Y axes.

## XZEXCH

Set this keyword to exchange the X and Z axes.

### YZEXCH

Set this keyword to exchange the Y and Z axes.

## Examples

To reset the transformation, rotate 30 degs about the X axis and do perspective transformation with the center of the projection at Z = -1, X=0, and Y=0, enter:

```
T3D, /RESET, ROT = [ 30,0,0], PERS = 1.
```

Transformations may be cascaded, for example:

```
T3D, /RESET, TRANS = [-.5,-.5,0], ROT = [0,0,45]
T3D, TRANS = [.5,.5,0]
```

The first command resets, translates the point (.5,.5,0) to the center of the viewport, then rotates 45 degrees counterclockwise about the Z axis. The second call to T3D moves the origin back to the center of the viewport.

# TAG_NAMES

The TAG_NAMES function returns a string array containing the names of the tags in a structure expression. It can also be used to determine the expression's structure name (if the structure has a name).

## Syntax

*Result* = TAG_NAMES( *Expression* [, /STRUCTURE_NAME] )

## Return Value

Returns structure tag names or the expression's structure name.

## Arguments

### Expression

The structure expression for which the tag names are returned. This argument must be of structure type. TAG_NAMES does not search for tags recursively, so if *Expression* is a structure containing nested structures, only the names of tags in the outermost structure are returned.

## Keywords

### STRUCTURE_NAME

Set this keyword to return a scalar string that contains the name of the structure instead of the names of the tags in the structure. If the structure is "anonymous", a null string is returned.

## Examples

Print the names of the tags in the system variable !P by entering:

```
PRINT, TAG_NAMES(!P)
```

IDL prints:

```
BACKGROUND CHARSIZE CHARTHICK CLIP COLOR FONT LINESTYLE MULTI
NOCLIP NOERASE NSUM POSITION PSYM REGION SUBTITLE SYMSIZE T
T3D THICK TITLE TICKLEN CHANNEL
```

Print the name of the structure in the system variable !P:

```
PRINT, TAG_NAMES(!P, /STRUCTURE_NAME)
```

IDL prints:

```
!PLT
```

CREATE_STRUCT, N_TAGS

# TAN

The TAN function computes the tangent of *X*.

## Syntax

*Result* = TAN(*X*)

## Return Value

Returns the tangent of the specified angle.

## Arguments

### X

The angle for which the tangent is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. If *X* is an array, the result has the same structure, with each element containing the tangent of the corresponding element of *X*.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

## Examples

```
; Find the tangent of 0.5 radians and store the result in
; the variable T:
T = TAN(0.5)
```

## Version History

Introduced: Original

## See Also

ATAN, TANH

# TANH

The TANH function returns the hyperbolic tangent of X.

## Syntax

*Result* = TANH(*X*)

## Return Value

Returns the single- or double-precision hyperbolic tangent.

## Arguments

### X

The value for which the hyperbolic tangent is desired, specified in radians. If *X* is double-precision floating or complex, the result is of the same type. All other types are converted to single-precision floating-point and yield floating-point results. TANH is defined as:

$$\tanh(x) = \frac{e^{x} - e^{-x}}{e^{x} + e^{-x}}$$

If *X* is an array, the result has the same structure, with each element containing the hyperbolic tangent of the corresponding element of *X*.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

## Examples

```
; Find the hyperbolic tangent of 1 radian and print the result:
PRINT, TANH(1)

; Plot the hyperbolic tangent from -5 to +5 with an increment
; of 0.1:
PLOT, TANH(FINDGEN(101)/10. - 5)
```

## Version History

ATAN, TAN

# TEK_COLOR

The TEK_COLOR procedure loads a 32-color colortable similar to the default Tektronix 4115 colortable. This colortable is useful because of its distinct colors.

By default, this palette consists of 32 colors. The first 9 colors are: Index 0=black, 1=white, 2=red, 3=green, 4=blue, 5=cyan, 6=magenta, 8=orange.

## Syntax

TEK_COLOR [, *Start_Index*, *Colors*]

## Arguments

### Start_Index

An optional starting index for the palette. The default is 0. If this argument is included, the colors are loaded into the current colortable starting at the specified index.

### Colors

The number of colors to load. The default is 32, which is also the maximum.

## Keywords

None.

## Version History

Introduced: Pre 4.0

## See Also

LOADCT, XLOADCT

# TEMPORARY

The TEMPORARY function returns a temporary copy of a variable, and sets the original variable to “undefined”. This function can be used to conserve memory when performing operations on large arrays, as it avoids making a new copy of results that are only temporary. In general, the TEMPORARY routine can be used to advantage whenever a variable containing an array on the left hand side of an assignment statement is also referenced on the right hand side.

## Syntax

*Result* = TEMPORARY(*Variable*)

## Return Value

Returns a copy of a specified variable.

## Arguments

### Variable

The variable to be referenced and deleted.

## Keywords

None.

## Examples

Assume the variable `A` is a large array of integers. The statement:

```
A = A + 1
```

creates a new array for the result of the addition, places the sum into the new array, assigns it to `A`, and then frees the old allocation of `A`. Total storage required is twice the size of `A`. The statement:

```
A = TEMPORARY(A) + 1
```

requires no additional space.

**Note**

If the operation performed on *Variable* requires that *Variable* be converted to another data type, there is no benefit to using TEMPORARY. For instance, if the

array A in the above example contained byte data rather than integer data, the array would have to be converted to integer type before the addition could be performed. In such a case, memory could not be re-used.

## Version History

Introduced: Pre 4.0

DELVAR

# TETRA_CLIP

The TETRA_CLIP function clips a tetrahedral mesh to an arbitrary plane in space and returns a tetrahedral mesh of the remaining portion. An auxiliary array of data may also be passed and clipped. This array can have multiple values for each vertex (the trailing array dimension must match the number of vertices in the Vertsin array).

A tetrahedral connectivity array consists of groups of four vertex index values. Each set of four index values specifies four vertices which define a single tetrahedron.

## Syntax

*Result* = TETRA_CLIP ( *Plane*, *Vertsin*, *Connin*, *Vertsout*, *Connout* [, AUXDATA_IN=*array*, AUXDATA_OUT=*variable*] [, CUT_VERTS=*variable*] )

## Return Value

The return value is the number of tetrahedra returned.

## Arguments

### Plane

Input four-element array describing the equation of the plane to be clipped to. The elements are the coefficients (*a*,*b*,*c*,*d*) of the equation $ax+by+cz+d=0$.

### Vertsin

Input array of tetrahedral vertices [3, *n*].

### Connin

Input tetrahedral mesh connectivity array.

### Vertsout

Output array of tetrahedral vertices [3, *n*].

### Connout

Output tetrahedral mesh connectivity array.

# Keywords

## AUXDATA_IN

Input array of auxiliary data. If present, these values are interpolated and returned through AUXDATA_OUT. The trailing array dimension must match the number of vertices in the Vertsin array.

## AUXDATA_OUT

Set this keyword to a named variable to contain an output array of interpolated auxiliary data.

## CUT_VERTS

Set this keyword to a named variable to contain an output array of vertex indices (into Vertsout) of the vertices which are considered to be ‘on’ the clipped surface.

# Version History

Introduced: 5.5

# TETRA_SURFACE

The TETRA_SURFACE function extracts a polygonal mesh as the exterior surface of a tetrahedral mesh. The output of this function is a polygonal mesh connectivity array that can be used with the input Verts array to display the outer surface of the tetrahedral mesh.

## Syntax

*Result* = TETRA_SURFACE (*Verts*, *Connin*)

## Return Value

Returns a polygonal mesh connectivity array. When used with the input vertex array, this function yields the exposed tetrahedral mesh surface.

## Arguments

### Verts

Array of vertices [3, *n*].

### Connin

Tetrahedral connectivity array.

## Keywords

None.

## Version History

Introduced: 5.5

# TETRA_VOLUME

The TETRA_VOLUME function computes properties of a tetrahedral mesh array. The basic property is the volume. An auxiliary data array may be supplied which specifies weights at each vertex which are interpolated through the volume during integration. Higher order moments (with respect to the X, Y, and Z axis) may be computed as well (with or without weights).

## Syntax

*Result* = TETRA_VOLUME ( *Verts*, *Conn* [, AUXDATA=*array*] [, MOMENT=*variable*] )

## Return Value

Returns the cumulative (weighted) volume of the tetrahedrons in the mesh.

## Arguments

### Verts

Array of vertices [3, *n*].

### Conn

Tetrahedral connectivity array.

## Keywords

### AUXDATA

Array of input auxiliary data (one value per vertex). If present, these values are used to weight a vertex. The volume area integral will linearly interpolate these values. The volume integral will linearly interpolate these values within each tetrahedra. The default weight is 1.0 which results in a basic volume.

### MOMENT

Set this keyword to a named variable that will contain a three-element float vector which corresponds to the first order moments computed with respect to the X, Y and Z axis. The computation is:

$$\vec{m} = \sum_{ntetras} v_i \vec{c}_i$$

where v is the (weighted) volume of the tetrahedron and c is the centroid of the tetrahedron, thus

$$\vec{m} / volume$$

yields the (weighted) centroid of the tetrahedral mesh.

## Version History

Introduced: 5.5

# THIN

The THIN function returns the “skeleton” of a bi-level image. The skeleton of an object in an image is a set of lines that reflect the shape of the object. The set of skeletal pixels can be considered to be the medial axis of the object. For a much more extensive discussion of skeletons and thinning algorithms, see *Algorithms for Graphics and Image Processing*, Theo Pavlidis, Computer Science Press, 1982. The THIN function is adapted from Algorithm 9.1 (the classical thinning algorithm).

On input, the bi-level image is a rectangular array in which pixels that compose the object have a nonzero value. All other pixels are zero. The result is a byte type image in which skeletal pixels are set to 2 and all other pixels are zero.

## Syntax

*Result* = THIN( *Image* [, /NEIGHBOR_COUNT] [, /PRUNE] )

## Return Value

Returns the thinned, two-dimensional byte array.

## Arguments

### Image

The two-dimensional image (array) to be thinned.

## Keywords

### NEIGHBOR_COUNT

Set this keyword to select an alternate form of output. In this form, output pixel values count the number of neighbors an individual skeletal pixel has (including itself). For example, a pixel that is part of a line will have the value 3 (two neighbors and itself). Terminal pixels will have the value 2, while isolated pixels have the value 1.

### PRUNE

If the PRUNE keyword is set, pixels with single neighbors are removed iteratively until only pixels with 2 or more neighbors exist. This effectively removes (or “prunes”) skeleton branches, leaving only closed paths.

## Examples

The following commands display the “thinned” edges of a Sobel filtered image:

```
; Open a file for reading:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])

; Create a byte array in which to store the image:
A = BYTARR(192, 192)

; Read first 192 by 192 image:
READU, 1, A

; Close the file:
CLOSE, 1

; Display the image:
TV, A, 0

; Apply the Sobel filter, threshold the image at value 75, and
; display the thinned edges:
TVSCL, THIN(SOBEL(A) GT 75), 1
```

## Version History

Introduced: Pre 4.0

# THREED

The THREED procedure plots a 2-D array as a pseudo 3-D plot. The orientation of the data is fixed. This routine is written in the IDL language. Its source code can be found in the file `threed.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

THREED, *A* [, *Sp*] [, TITLE=*string*] [, XTITLE=*string*] [, YTITLE=*string*]

## Arguments

### A

The two-dimensional array to plot.

### Sp

The spacing between plot lines. If *Sp* is omitted, the spacing is set to: (MAX(*A*)-MIN(*A*))/ROWS. If *Sp* is negative, hidden lines are not removed.

## Keywords

### TITLE

Set this keyword to the main plot title.

### XTITLE

Set this keyword to the X axis title.

### YTITLE

Set this keyword to the Y axis title.

## Examples

```
; Create a 2-D dataset:
A = -SHIFT(DIST(30), 15, 15)
; Make a THREED plot:
THREED, A
; Compare to SURFACE:
SURFACE, A
```

## Version History

SURFACE

# TIME_TEST2

The TIME_TEST2 procedure is a general-purpose IDL benchmark program that performs approximately 20 common operations and prints the time required.

This routine is written in the IDL language. Its source code can be found in the file `time_test.pro` in the `lib` subdirectory of the IDL distribution. This file also contains the procedure GRAPHICS_TIMES, used to time graphical operations.

## Syntax

TIME_TEST2 [, *Filename*]

## Arguments

### Filename

An optional string that contains the name of output file for the results of the time test.

## Keywords

None.

## Examples

```
; Run the computational tests:
TIME_TEST2

; Run the graphics tests. Note that TIME_TEST2 must be compiled
; before GRAPHICS_TIMES will run:
GRAPHICS_TIMES
```

## Version History

Introduced: 4.0

## See Also

SYSTIME

# TIMEGEN

The TIMEGEN function returns an array, with specified dimensions, of double-precision floating-point values that represent times in terms of Julian dates.

The Julian date is the number of days elapsed since Jan. 1, 4713 B.C.E., plus the time expressed as a day fraction. Following the astronomical convention, the day is defined to start at 12 PM (noon). Julian date 0.0d is therefore Jan. 1, 4713 B.C.E. at 12:00:00.

The first value of the returned array corresponds to a Julian date start time, and each subsequent value corresponds to the next Julian date in the sequence. The sequence is determined by specifying the time unit (such as months or seconds) and the step size, or spacing, between the units. You can also construct more complicated arrays by including smaller time units within each major time interval.

A small offset is added to each Julian date to eliminate roundoff errors when calculating the day fraction from the hour, minute, second. This offset is given by the larger of EPS and EPS*Julian, where Julian is the integer portion of the Julian date and EPS is the double-precision floating-point precision parameter from MACHAR. For typical Julian dates the offset is approximately $6x10^{-10}$ (which corresponds to $5x10^{-5}$ seconds). This offset ensures that when the Julian date is converted back to the hour, minute, and second, the hour, minute, and second will have the same integer values.

**Tip**

Because of the large magnitude of the Julian date (1 Jan 2000 is Julian day 2451545), the precision of most Julian dates is limited to 1 millisecond (0.001 seconds). If you are not interested in the date itself, you can improve the precision by subtracting a large offset or setting the START keyword to zero.

**Note**

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

## Syntax

*Result* = TIMEGEN( [*D1,...,D8* | , FINAL=*value*] [, DAYS=*vector*] [, HOURS=*vector*] [, MINUTES=*vector*] [, MONTHS=*vector*] [, SECONDS=*vector*] [, START=*value*] [, STEP_SIZE=*value*] [, UNITS=*string*] [, YEAR=*value*] )

# Return Value

Returns the specified time values.

# Arguments

## $D_i$

The dimensions of the result. The dimension parameters may be any scalar expression. Up to eight dimensions may be specified. If the dimension arguments are not integer values, IDL will truncate them to integer values before creating the new array. The dimension arguments are required unless keyword FINAL is set, in which case they are ignored.

# Keywords

## DAYS

Set this keyword to a scalar or a vector giving the day values that should be included within each month. This keyword is ignored if the UNITS keyword is set to “Days”, “Hours”, “Minutes”, or “Seconds”.

**Note**

Day values that are beyond the end of the month will be set equal to the last day for that month. For example, setting `DAY=[31]` will automatically return the last day in each month.

## FINAL

Set this keyword to a double-precision value representing the Julian date/time to use as the last value in the returned array. In this case, the dimension arguments are ignored and *Result* is a one-dimensional array, with the number of elements depending upon the step size. The FINAL time may be less than the START time, in which case STEP_SIZE should be negative.

**Note**

If the step size is not an integer then the last element may not be equal to the FINAL time. In this case, TIMEGEN will return enough elements such that the last element is less than or equal to FINAL.

## HOURS

Set this keyword to a scalar or a vector giving the hour values that should be included within each day. This keyword is ignored if UNITS is set to “Hours”, “Minutes”, or “Seconds”.

## MINUTES

Set this keyword to a scalar or a vector giving the minute values that should be included within each hour. This keyword is ignored if UNITS is set to “Minutes” or “Seconds”.

## MONTHS

Set this keyword to a scalar or a vector giving the month values that should be included within each year. This keyword is ignored if UNITS is set to “Months”, “Days”, “Hours”, “Minutes”, or “Seconds”.

## SECONDS

Set this keyword to a scalar or a vector giving the second values that should be included within each minute. This keyword is ignored if UNITS is set to “Seconds”.

## START

Set this keyword to a double-precision value representing the Julian date/time to use as the first value in the returned array. The default is 0.0d [corresponding to January 1, 4713 B.C.E. at 12 pm (noon)].

**Note**

If subintervals are provided by MONTHS, DAYS, HOURS, MINUTES, or SECONDS, then the first element may not be equal to the START time. In this case the first element in the returned array will be greater than or equal to START.

**Tip**

Other array generation routines in IDL (such as FINDGEN) do not allow you to specify a starting value because the resulting array can be added to a scalar representing the start value. For TIMEGEN it is correct to add a scalar to the array if the units are days, hours, minutes, seconds, or sub-seconds. For example:

```
MyTimes = TIMEGEN(365, UNITS="Days") + SYSTIME(/JULIAN)
```

However, if the units are months or years, the start value is necessary because the number of days in a month or year can vary depending upon the year in which they

fall (for instance, consider leap years). For example:

```
MyTimes = TIMEGEN(12, UNITS="Months", START=JULDAY(1,1,2000))
```

## STEP_SIZE

Set this keyword to a scalar value representing the step size between the major intervals of the returned array. The step size may be negative. The default step size is 1. When the UNITS keyword is set to “Years” or “Months”, the STEP_SIZE value is rounded to the nearest integer.

## UNITS

Set this keyword to a scalar string indicating the time units to be used for the major intervals for the generated array. Valid values include:

- “Years” or “Y”
- “Months” or “M”
- “Days” or “D”
- “Hours” or “H”
- “Minutes” or “I”
- “Seconds” or “S”

The case (upper or lower) is ignored. If this keyword is not specified, then the default for UNITS is the time unit that is larger than the largest keyword present:

| Largest Keyword Present | Default UNITS |
|---|---|
| SECONDS=*vector* | “Minutes” |
| MINUTES=*vector* | “Hours” |
| HOURS=*vector* | “Days” |
| DAYS=*vector* | “Months” |
| MONTHS=*vector* | “Years” |
| YEAR=*value* | “Years” |

*Table 93: Defaults for the UNITS keyword*

If none of the above keywords are present, the default is UNITS="Days".

### YEAR

Set this keyword to a scalar giving the starting year. If YEAR is specified then the starting year from START is ignored.

## Examples

Generate an array of 366 time values that are one day apart starting with January 1, 2000:

```
MyDates = TIMEGEN(366, START=JULDAY(1,1,2000))
```

Generate an array of 20 time values that are 12 hours apart starting with the current time:

```
MyTimes = TIMEGEN(20, UNITS='Hours', STEP_SIZE=12, $
   START=SYSTIME(/JULIAN))
```

Generate an array of time values that are 1 hour apart from 1 January 2000 until the current time:

```
MyTimes = TIMEGEN(START=JULDAY(1,1,2000), $
   FINAL=SYSTIME(/JULIAN), UNITS='Hours')
```

Generate an array of time values composed of seconds, minutes, and hours that start from the current hour:

```
MyTimes = TIMEGEN(60, 60, 24, $
   START=FLOOR(SYSTIME(/JULIAN)*24)/24d, UNITS='S')
```

Generate an array of 24 time values with monthly intervals, but with subintervals at 5 PM on the first and fifteenth of each month:

```
MyTimes = TIMEGEN(24, START=FLOOR(SYSTIME(/JULIAN)), $
   DAYS=[1,15], HOURS=17)
```

## Version History

Introduced: 5.4

"Format Codes" in Chapter 10 of the *Building IDL Applications* manual, CALDAT, JULDAY, LABEL_DATE, SYSTIME

# TM_TEST

The TM_TEST function computes the Student's T-statistic and the probability that two sample populations *X* and *Y* have significantly different means. *X* and *Y* may be of different lengths. The default assumption is that the data is drawn from populations with the same true variance. This type of test is often referred to as the t-means test.

The T-statistic for sample populations *x* and *y* with means $\bar{x}$ and $\bar{y}$ is defined as:

$$T = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{\sum_{j=0}^{N-1} (x_i - \bar{x})^2 + \sum_{j=0}^{M-1} (y_i - \bar{y})^2}{(N + M - 2)} \left(\frac{1}{N} + \frac{1}{M}\right)}}$$

where $x = (x_0, x_1, x_2, ..., x_{N-1})$ and $y = (y_0, y_1, y_2 ..., y_{M-1})$

This routine is written in the IDL language. Its source code can be found in the file `tm_test.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = TM_TEST( *X*, *Y* [, /PAIRED] [, /UNEQUAL] )

## Return Value

The result is a two-element vector containing the T-statistic and its significance. The significance is a value in the interval [0.0, 1.0]; a small value (0.05 or 0.01) indicates that *X* and *Y* have significantly different means.

## Arguments

### X

An *n*-element integer, single-, or double-precision floating-point vector.

### Y

An *m*-element integer, single-, or double-precision floating-point vector. If the PAIRED keyword is set, *X* and *Y* must have the same number of elements.

## Keywords

### PAIRED

If this keyword is set, *X* and *Y* are assumed to be paired samples and must have the same number of elements.

### UNEQUAL

If this keyword is set, *X* and *Y* are assumed to be from populations with unequal variances.

## Examples

```
; Define two n-element sample populations.
X = [257, 208, 296, 324, 240, 246, 267, 311, 324, 323, 263, $
     305, 270, 260, 251, 275, 288, 242, 304, 267]
Y = [201, 56, 185, 221, 165, 161, 182, 239, 278, 243, 197, $
     271, 214, 216, 175, 192, 208, 150, 281, 196]

; Compute the Student's t-statistic and its significance assuming
; that X and Y belong to populations with the same true variance:
PRINT, TM_TEST(X, Y)
```

IDL prints:

```
5.52839  2.52455e-06
```

The result indicates that *X* and *Y* have significantly different means.

FV_TEST, KW_TEST, RS_TEST, S_TEST

# TOTAL

The TOTAL function returns the sum of the elements of *Array*. The sum of the array elements over a given dimension is returned if the *Dimension* argument is present.

## Syntax

*Result* = TOTAL( *Array* [, *Dimension*] [, /CUMULATIVE] [, /DOUBLE] [, /NAN] )

## Return Value

Returns the array sum for the specified dimensions.

## Arguments

### Array

The array to be summed. This array can be of any basic type except string. If *Array* is double-precision floating-point, complex, or double-precision complex, the result is of the same type. Otherwise, the result is single-precision floating-point.

### Dimension

The dimension over which to sum, starting at one. If this argument is not present or zero, the scalar sum of all the array elements is returned. If this argument is present, the result is an array with one less dimension than *Array*. For example, if the dimensions of *Array* are $N_1$, $N_2$, $N_3$, and *Dimension* is 2, the dimensions of the result are ($N_1$, $N_3$), and element *(i,j)* of the result contains the sum:

$$\sum_{k=0}^{N_2-1} A_{i,k,j}$$

## Keywords

### CUMULATIVE

If this keyword is set, the result is an array of the same size as the input, with each element, i, containing the sum of the input array elements 0 to i. This keyword also works with the Dimension parameter, in which case the sum is performed over the given dimension.

## DOUBLE

Set this keyword to perform the summation in double-precision floating-point.

## NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point value NaN in the input data. Elements with the value NaN are treated as missing data. (See "Special Floating-Point Values" in Chapter 18 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

**Note**

Since the value NaN is treated as missing data, if *Array* contains only NaN values the TOTAL routine will return 0.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

The thread pool is used for non-cumulative sums, and is not used if the CUMULATIVE keyword is specified. In a cumulative sum, each result value depends on all of the previous results, so overlapped execution is not possible.

You should be aware that when summing a large number of values, the result from TOTAL can depend heavily upon the order in which the numbers are added. Since the thread pool will add values in a different order, you may obtain a different — but equally correct — result than that obtained using the standard non-threaded implementation. This effect occurs because TOTAL uses floating point arithmetic, and the mantissa of a floating point value has a fixed number of significant digits. The effect is especially obvious when using single precision arithmetic, but can also affect double precision computations. Such differences do not mean that the sums are incorrect. Rather, they mean that they are equal within the ability of the floating point representation used to represent them. For more information on floating-point numbers, see "Accuracy & Floating-Point Operations" in Chapter 22 of the *Using IDL* manual.

It is also worth noting that this effect, while illustrated by the use of the thread pool, is not caused by the use of threading. It is simply caused by the different order in which

the numbers are summed, as can be illustrated by the following non-threaded example:

```
vec = FINDGEN(100000)
PRINT, TOTAL(vec, /TPOOL_NO) - TOTAL(REVERSE(vec), /TPOOL_NO)
```

IDL prints:

```
-96768.0
```

As you can see, the small floating-point errors can accumulate across the sum of a large number of values.

**Note**

The computation above was done on a Sun Sparc workstation. Your result will depend on the architecture of your CPU; it may be slightly different, and in the notable case of Intel-compatible X86 CPUs may actually be zero due to the use of internal 80-bit floating point registers on that CPU which give it better than double precision accuracy for some computations. Nonetheless, you should be aware of the fact that the order of operations can influence the result.

# Examples

## Example 1

This example sums the elements of a one-dimensional array:

```
; Define a one-dimensional array:
A = [20, 10, 5, 5, 3]

; Sum the elements of the array:
SUMA = TOTAL([20, 10, 5, 5, 3])

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of A = ', SUMA
```

IDL prints:

```
A =   20   10   5   5   3
Sum of A =   43.0000
```

## Example 2

The results are different when a multi-dimensional array is used:

```
; Define a multi-dimensional array:
A = FINDGEN(5,5)
```

```
; Sum each of the rows in A:
SUMROWS = TOTAL(A, 1)

; Sum each of the columns in A:
SUMCOLS = TOTAL(A, 2)

; Print the results:
PRINT, 'A = ', A
PRINT, 'Sum of each row:', SUMROWS
PRINT, 'Sum of each column:', SUMCOLS
```

IDL prints:

```
A = 0.000000   1.00000   2.00000   3.00000   4.00000
    5.00000    6.00000   7.00000   8.00000   9.00000
    10.0000    11.0000   12.0000   13.0000   14.0000
    15.0000    16.0000   17.0000   18.0000   19.0000
    20.0000    21.0000   22.0000   23.0000   24.0000

Sum of each row:  10.0000  35.0000  60.0000  85.0000  110.000

Sum of each column:  50.0000  55.0000  60.0000  65.0000  70.0000
```

# TRACE

The TRACE function computes the trace of an *n* by *n* array.

This routine is written in the IDL language. Its source code can be found in the file `trace.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = TRACE( *A* [, /DOUBLE] )

## Return Value

Returns the sum of the values along the array diagonal.

## Arguments

### A

An *n* by *n* real or complex array.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Define an array:
A = [[ 2.0,1.0,  1.0, 1.5], $
     [ 4.0, -6.0,  0.0, 0.0], $
     [-2.0,  7.0,  2.0, 2.5], $
     [ 1.0,  0.5,  0.0, 5.0]]

; Compute the trace of A:
result = TRACE(A)

;Print the result:
PRINT, 'TRACE(A) = ', result
```

IDL prints:

```
TRACE(A) =   3.00000
```

TOTAL

# TrackBall Object

See Appendix , “TrackBall”

# TRANSPOSE

The TRANSPOSE function returns the transpose of *Array*. If an optional permutation vector is provided, the dimensions of *Array* are rearranged as well.

## Syntax

*Result* = TRANSPOSE( *Array* [, *P*] )

## Return Value

Returns the reflection of the array along a diagonal.

## Arguments

### Array

The array to be transposed.

### P

A vector specifying how the dimensions of *Array* will be permuted. The elements of *P* correspond to the dimensions of *Array*; the *i*th dimension of the output array is dimension *P*[*i*] of the input array. Each element of the vector *P* must be unique. Dimensions start at zero and can not be repeated.

If *P* is not present, the order of the dimensions of *Array* is reversed.

## Keywords

None.

## Examples

### Example 1

Print a simple array and its transpose by entering:

```
; Create an array:
A = INDGEN(3,3)
TRANSA = TRANSPOSE(A)
```

```
; Print the array and its transpose:
PRINT, 'A:'
PRINT, A
PRINT, 'Transpose of A:'
PRINT, TRANSA
```

IDL prints:

```
A:
   0  1  2
   3  4  5
   6  7  8

Transpose of A:
   0  3  6
   1  4  7
   2  5  8
```

### Example 2

This example demonstrates multi-dimensional transposition:

```
; Create the array:
A = INDGEN(2, 3, 4)

; Take the transpose, reversing the order of the indices:
B = TRANSPOSE(A)

; Re-order the dimensions of A, so that the second dimension
; becomes the first, the third becomes the second, and the first
; becomes the third:
C = TRANSPOSE(A, [1, 2, 0])

; View the sizes of the three arrays:
HELP, A, B, C
```

IDL prints:

```
A   INT  = Array[2, 3, 4]
B   INT  = Array[4, 3, 2]
C   INT  = Array[3, 4, 2]
```

# TRI_SURF

The TRI_SURF function interpolates a regularly- or irregularly-gridded set of points with a smooth quintic surface.

TRI_SURF is similar to MIN_CURVE_SURF but the surface fitted is a smooth surface, not a minimum curvature surface. TRI_SURF has the advantage of being much more efficient for larger numbers of points.

**Note**

The TRI_SURF function is designed to interpolate low resolution data. Large arrays may cause TRI_SURF to issue the following error message:
`Partial Derivative Approximation Failed to Converge`"
In such cases, interpolation is most likely unnecessary.

This routine is written in the IDL language. Its source code can be found in the file `tri_surf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = TRI_SURF( *Z* [, *X*, *Y*] [, /EXTRAPOLATE] [, MISSING=*value*] [, /REGULAR] [, XGRID=*[xstart, xspacing]* | [, XVALUES=*array*]] [, YGRID=*[yxstart, yspacing]* | [, YVALUES=*array*]] [, GS=*[xspacing, yspacing]*] [, BOUNDS=*[xmin, ymin, xmax, ymax]*] [, NX=*value*] [, NY=*value*] )

## Return Value

The result is s a two-dimensional floating-point array containing the interpolated surface, sampled at the grid points.

## Arguments

### X, Y, Z

arrays containing the X, Y, and Z coordinates of the data points on the surface. Points need not be regularly gridded. For regularly gridded input data, X and Y are not used: the grid spacing is specified via the XGRID and YGRID (or XVALUES and YVALUES) keywords, and Z must be a two dimensional array. For irregular grids, all three parameters must be present and have the same number of elements.

# Keywords

## EXTRAPOLATE

Set this keyword to cause TRI_SURF to extrapolate the surface to points outside the convex hull of input points. This keyword has no effect if the input points are regularly gridded.

## LINEAR

Set this keyword to use linear interpolation, without gradient estimates, instead of quintic interpolation. Linear interpolation does not extrapolate, although it is faster and more numerically stable.

## MISSING

Set this keyword equal to the value to which points outside the convex hull of input points should be set. The default is 0. This keyword has no effect if the input points are regularly gridded.

**Input Grid Description:**

## REGULAR

If set, the *Z* parameter is a two-dimensional array of dimensions (*n*,*m*), containing measurements over a regular grid. If any of XGRID, YGRID, XVALUES, or YVALUES are specified, REGULAR is implied. REGULAR is also implied if there is only one parameter, *Z*. If REGULAR is set, and no grid specifications are present, the grid is set to (0, 1, 2, ...).

## XGRID

A two-element array, [*xstart*, *xspacing*], defining the input grid in the *x* direction. Do not specify both XGRID and XVALUES.

## XVALUES

An *n*-element array defining the *x* locations of Z[*i*,*j*]. Do not specify both XGRID and XVALUES.

## YGRID

A two-element array, [*ystart*, *yspacing*], defining the input grid in the *y* direction. Do not specify both YGRID and YVALUES.

### YVALUES

An *n*-element array defining the *y* locations of Z[*i*,*j*]. Do not specify both YGRID and YVALUES.

**Output Grid Description:**

**Note**

The output grid must enclose the convex hull of the input points.

### GS

The output grid spacing. If present, GS must be a two-element vector [*xs*, *ys*], where *xs* is the horizontal spacing between grid points and *ys* is the vertical spacing. The default is based on the extents of *x* and *y*. If the grid starts at *x* value *xmin* and ends at *xmax*, then the default horizontal spacing is (*xmax* - *xmin*)/(NX-1). YS is computed in the same way. The default grid size, if neither NX or NY are specified, is 26 by 26.

### BOUNDS

If present, BOUNDS must be a four-element array containing the grid limits in *x* and *y* of the output grid: [*xmin*, *ymin*, *xmax*, *ymax*]. If not specified, the grid limits are set to the extent of *x* and *y*.

### NX

The output grid size in the *x* direction. NX need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

### NY

The output grid size in the *y* direction. NY need not be specified if the size can be inferred from GS and BOUNDS. The default value is 26.

## Examples

### Example 1

Regularly gridded case:

```
; Make some random data
Z = randomu(seed, 5, 6)

; Interpolate to a 26 x 26 grid:
CONTOUR, TRI_SURF(Z, /REGULAR)
```

### Example 2

Irregularly gridded case:

```
; Make a random set of points that lie on a Gaussian:
N = 15
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; The Gaussian:
Z = EXP(-2 * ((X-.5)^2 + (Y-.5)^2))

; Use a 26 by 26 grid over the rectangle bounding x and y.
; Get the surface:
R = TRI_SURF(Z, X, Y)

; Alternatively, get a surface over the unit square, with spacing
; of 0.05:
R = TRI_SURF(z, x, y, GS=[0.05, 0.05], BOUNDS=[0,0,1,1])

; Alternatively, get a 10 by 10 surface over the rectangle bounding
; x and y:
R = TRI_SURF(z, x, y, NX=10, NY=10)
```

CONTOUR, MIN_CURVE_SURF

# TRIANGULATE

The TRIANGULATE procedure constructs a Delaunay triangulation of a planar set of points. Delaunay triangulations are very useful for the interpolation, analysis, and visual display of irregularly-gridded data. In most applications, after the irregularly gridded data points have been triangulated, the function TRIGRID is invoked to interpolate surface values to a regular grid.

Since Delaunay triangulations have the property that the circumcircle of any triangle in the triangulation contains no other vertices in its interior, interpolated values are only computed from nearby points.

TRIANGULATE can, optionally, return the adjacency list that describes, for each node, the adjacent nodes in the Delaunay triangulation. With this list, the Voronoi polygon (the polygon described by the set of points which are closer to that node than to any other node) can be computed for each node. This polygon contains the area influenced by its associated node. Tiling of the region in this manner is also called Dirichlet, Wigner-Seithz, or Thiessen tessellation.

The grid returned by the TRIGRID function can be input to various routines such as SURFACE, TV, and CONTOUR. See the description of TRIGRID for an example.

TRIANGULATE and TRIDGRID can also be used to perform gridding and interpolation over the surface of a sphere. The interpolation is $C_1$ continuous, meaning that the result is continuous over both the function value and its first derivative. This feature is ideal for interpolating an irregularly-sampled dataset over part or all of the surface of the earth (or other (spherical) celestial bodies). Extrapolation outside the convex hull of sample points is also supported. To perform spherical gridding, you must include the FVALUE and SPHERE keywords described below. The spherical gridding technique used in IDL is based on the paper "Interpolation of Data on the Surface of a Sphere", R. Renka, *Oak Ridge National Laboratory Report ORNL/CSD-108*, 1982.

## Syntax

TRIANGULATE, *X*, *Y*, *Triangles* [, *B*] [, CONNECTIVITY=*variable*]
[, SPHERE=*variable* [, /DEGREES]] [, FVALUE=*variable*] [, REPEATS=*variable*]

## Arguments

### X

An array that contains the X coordinates of the points to be triangulated.

### Y

An array that contains the Y coordinates of the points to be triangulated. Parameters *X* and *Y* must have the same number of elements.

### Triangles

A named variable that, on exit, contains the list of triangles in the Delaunay triangulation of the points specified by the X and Y arguments. Triangles is a longword array dimensioned (3, *number of triangles*), where `Triangles[0, i]`, `Triangles[1, i]`, and `Triangles[2, i]` contain the indices of the vertices of the *i*-th triangle (i.e., `X[Tr[*, i]]` and `Y[Triangles[*, i]]` are the X and Y coordinates of the vertices of the *i*-th triangle).

### B

An optional, named variable that, upon return, contains a list of the indices of the boundary points in counterclockwise order.

## Keywords

### CONNECTIVITY

Set this keyword to a named variable in which the adjacency list for each of the *N* nodes (xy point) is returned. The list has the following form:

Each element *i*, $0 \le i < N$, contains the starting index of the connectivity list for node *i* within the list array. To obtain the adjacency list for node i, extract the list elements from LIST[*i*] to LIST[*i*+1]-1.

The adjacency list is ordered in the counter-clockwise direction. The first item on the list of boundary nodes is the subscript of the node itself. For interior nodes, the list contains the subscripts of the adjacent nodes in counter-clockwise order.

For example, the call:

```
TRIANGULATE, X, Y, CONNECTIVITY = LIST
```

returns the adjacency list in the variable LIST. The subscripts of the nodes adjacent to X[i] and Y[i] are contained in the array:

```
LIST[LIST[i] : LIST[i+1]-1]
```

### DEGREES

Set this keyword to indicate that the *X* and *Y* arguments contain longitude and latitude coordinates specified in degrees. This keyword is only effective if the SPHERE

keyword is specified. If DEGREES is not set, *X* and *Y* are assumed to be specified in radians when a spherical triangulation is performed.

### FVALUE

Set this keyword to a named variable that contains sample values for each longitude/latitude point in a spherical triangulation. On output, the elements of FVALUE are rearranged to correspond to the new ordering of *X* and *Y* (as described in the SPHERE keyword, below). This reordered array can be passed to TRIGRID to complete the interpolation.

### REPEATS

Set this keyword to a named variable to return a (2, *n*) list of the indices of duplicated points. That is, for each *i*,

```
X[REPEATS[0,i]] = X[REPEATS[1,i]]
```

and

```
Y[REPEATS[0,i]] = Y[REPEATS[1,i]]
```

**Note**

Use the GRID_INPUT procedure to handle repeated points (duplicate locations).

### SPHERE

Set this keyword to a named variable in which the results from a spherical triangulation are returned. This result is a structure that can be passed to TRIGRID to perform spherical gridding. The structure contains the 3D Cartesian locations sample points and the adjacency list that describes the triangulation.

When spherical triangulation is performed, *X* and *Y* are interpreted as longitude and latitude, in either degrees or radians (see the DEGREE keyword, above). Also, the order of the elements within the *X* and *Y* parameters is rearranged (see the FVALUE keyword, above).

## Examples

For some examples using the TRIANGULATE routine, see the TRIGRID function.

## Version History

Introduced: Pre 4.0

SPH_SCAT, TRIGRID

# TRIGRID

Given data points defined by the parameters *X*, *Y*, and *Z* and a triangulation of the planar set of points determined by *X* and *Y*, the TRIGRID function returns a regular grid of interpolated *Z* values. Linear or smooth quintic polynomial interpolation can be selected. Extrapolation for gridpoints outside of the triangulation area is also an option.

An input triangulation can be constructed using the procedure TRIANGULATE. Together, the TRIANGULATE procedure and the TRIGRID function constitute IDL's solution to the problem of irregularly-gridded data, including spherical gridding.

## Syntax

*Result* = TRIGRID( *X*, *Y*, *Z*, *Triangles* [, *GS*, *Limits*] )

For spherical gridding: *Result* = TRIGRID( *F* , *GS*, *Limits*, SPHERE=*S* )

**Keywords:** [, /DEGREES] [, EXTRAPOLATE=*array* | , /QUINTIC] [, INPUT=*variable*] [, MAX_VALUE=*value*] [, MIN_VALUE=*value*] [, MISSING=*value*] [, NX=*value*] [, NY=*value*] [, SPHERE=*variable*] [, XGRID=*variable*] [, YGRID=*variable*] [, XOUT=*vector*, YOUT=*vector*]

## Return Value

The resulting grid is a two-dimensional array with user-specified bounds and spacing. The data type of the resulting grid is either floating-point or double-precision floating-point depending upon the data type of *Z*.

## Arguments

### X, Y, Z

Input arrays of X, Y, and Z coordinates of data points. Integer, long, double-precision and floating-point values are allowed. In addition, *Z* can be a complex array. All three arrays must have the same number of elements.

### F

When performing a spherical gridding, this argument should be the named variable that contains the rearranged sample values that were returned by TRIANGULATE's FVALUE keyword.

### Triangles

A longword array of the form output by TRIANGULATE. That is, *Triangles* has the dimensions (3, *number of triangles*) and, for each *i*, `Triangles[0,i]`, `Triangles[1,i]`, and `Triangles[2,i]` are the indices of the vertices of the *i*-th triangle.

### GS

If present, *GS* should be a two-element vector [*XS, YS*], where *XS* is the horizontal spacing between grid points and *YS* is the vertical spacing. The default is based on the extents of *X* and *Y*. If the grid starts at *X* value $x_0$ and ends at $x_1$,then the horizontal spacing is

$(x_1 - x_0)/50$

The default for *YS* is computed in the same way. Since the default grid spacing divides each axis into 50 intervals and produces 51 samples, TRIGRID returns a grid with dimensions (51, 51).

If the NX or NY keywords are set to specify the output grid dimensions, either or both of the values of *GS* may be set to 0. In this case, the grid spacing is computed as the respective range divided by the dimension minus one:

$(x_1 - x_0)/(NX-1)$ and $(y_1 - y_0)/(NY-1)$

For spherical gridding, *GS* is assumed to be specified in radians, unless the DEGREES keyword is set.

### Limits

If present, *Limits* should be a four-element vector $[x_0, y_0, x_1, y_1]$ that specifies the data range to be gridded ($x_0$ and $y_0$ are the lower X and Y data limits, and $x_1$ and $y_1$ are the upper limits). The default for *Limits* is:

```
[MIN(X), MIN(Y), MAX(X), MAX(Y)]
```

If the NX or NY keywords are not specified, the size of the grid produced is specified by the value of *Limits*. If the NX or NY keywords are set to specify the output grid dimensions, a grid of the specified size will be used regardless of the value of *Limits*.

## Keywords

### DEGREES

For a spherical gridding, set this keyword to indicate that the grid spacing (the *GS* argument) is specified in degrees rather than radians.

## EXTRAPOLATE

Set this keyword equal to an array of boundary node indices (as returned by the optional parameter B of the TRIANGULATE procedure) to extrapolate to grid points outside the triangulation. The extrapolation is not smooth, but should give acceptable results in most cases.

Setting this keyword sets the quintic interpolation mode, as if the QUINTIC keyword has been specified.

## INPUT

Set this keyword to a named variable (which must be an array of the appropriate size to hold the output from TRIGRID) in which the results of the gridding are returned. This keyword is provided to make it easy and memory-efficient to perform multiple calls to TRIGRID. The interpolates within each triangle overwrite the array and the array is not initialized.

## MAX_VALUE

Set this keyword to a value that represents the maximum *Z* value to be gridded. Data larger than this value are treated as missing data and are not gridded.

## MIN_VALUE

Set this keyword to a value that represents the minimum *Z* value to be gridded. Data smaller than this value are treated as missing data and are not gridded.

## MISSING

The *Z* value to be used for grid points that lie outside the triangles in *Triangles*. The default is 0. This keyword also applies to data points outside the range specified by MIN_VALUE and MAX_VALUE.

**Note**

Letting MISSING default to 0 does not always produce the same result as explicitly setting it to 0. For example, if you specify INPUT and not EXTRAPOLATE, letting MISSING default to 0 will result in the INPUT values being used for data outside the Triangles; explicitly setting MISSSING to 0 will result in 0 being used for the data outside the Triangles.

## NX

The output grid size in the *x* direction. The default value is 51.

## NY

The output grid size in the *y* direction. The default value is 51.

## QUINTIC

If QUINTIC is set, smooth interpolation is performed using Akima's quintic polynomials from "A Method of Bivariate Interpolation and Smooth Surface Fitting for Irregularly Distributed Data Points" in *ACM Transactions on Mathematical Software*, 4, 148-159. The default method is linear interpolation.

Derivatives are estimated by Renka's global method in "A Triangle-Based C1 Interpolation Method" in *Rocky Mountain Journal of Mathematics*, vol. 14, no. 1, 1984.

QUINTIC is not available for complex data values. Setting the EXTRAPOLATE keyword implies the use of quintic interpolation; it is not necessary to specify both.

## SPHERE

For a spherical gridding, set this keyword to the named variable that contains the results of the spherical triangulation returned by TRIANGULATE's SPHERE keyword.

## XGRID

Set this keyword to a named variable that will contain a vector of *X* values for the output grid.

## XOUT

Set this keyword to a vector specifying the output grid *X* values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If XOUT is specified, YOUT must also be specified. If keyword NX is also supplied then only the first NX points of XOUT will be used.

## YGRID

Set this keyword to a named variable that will contain a vector of *Y* values for the output grid.

The following table shows the interrelationships between the keywords EXATRAPOLATE, INPUT, MAX_VALUE, MIN_VALUE, MISSING, and QUINTIC.

| INPUT | EXTRAPOLATE | MISSING | Not in Triangles | Beyond MIN_VALUE, MAX_VALUE |
|---|---|---|---|---|
| no | no | no | uses 0 | uses 0 |
| no | no | yes | uses MISSING | uses MISSING |
| no | yes | no | EXTRAPOLATEs | uses 0 |
| no | yes | yes | EXTRAPOLATEs | uses MISSING |
| yes | no | no | uses INPUT | uses INPUT |
| yes | no | yes | uses MISSING | uses MISSING |
| yes | yes | no | EXTRAPOLATEs | uses INPUT |
| yes | yes | yes | EXTRAPOLATEs | uses MISSING |

*Table 94: Keyword Interrelationships for the TRIGRID function*

### YOUT

Set this keyword to a vector specifying the output grid *Y* values. If this keyword is supplied, the *GS* and *Limits* arguments are ignored. Use this keyword to specify irregularly spaced rectangular output grids. If keyword NY is also supplied then only the first NY points of YOUT will be used.

## Examples

### Example 1

This example creates and displays a 50 point random normal distribution. The random points are then triangulated, with the triangulation displayed. Next, the interpolated surface is computed and displayed using linear and quintic interpolation. Finally, the smooth extrapolated surface is generated and shown.

```
PRO TrigridExample

; Make 50 normal x, y points:
x = RANDOMN(seed, 50)
```

```

## Example 2

This example shows how to perform spherical gridding:

```
PRO SphericalGrid
; Create some random longitude points:
lon = RANDOMU(seed, 50) * 360. - 180.

; Create some random latitude points:
lat = RANDOMU(seed, 50) * 180. - 90.

; Make a fake function value to be passed to FVALUE. The system
; variable !DTOR contains the conversion value for degrees to
; radians.
f = SIN(lon * !DTOR)^2 * COS(lat * !DTOR)

; Perform a spherical triangulation:
TRIANGULATE, lon, lat, tr, $
    SPHERE=s, FVALUE=f, /DEGREES

; Perform a spherical triangulation using the values returned from
; TRIANGULATE. The result, r, is a 180 by 91 element array:
r=TRIGRID(f, SPHERE=s, [2.,2.],$
   [-180.,-90.,178.,90.], /DEGREES)

; Display the surface
SURFACE, r
END
```

## Example 3

This example demonstrates the use of the INPUT keyword:

```
PRO TrigridInputKeyword

; Make 50 normal x, y points:
x = RANDOMN(seed, 50)
y = RANDOMN(seed, 50)
```

```
; Make the Gaussian:
z = EXP(-(x^2 + y^2))

; Show points:
PLOT, x, y, psym=1

; Obtain triangulation:
TRIANGULATE, x, y, tr, b

;Show the triangles.
FOR i=0, N_ELEMENTS(tr)/3-1 DO BEGIN $
   ; Subscripts of vertices [0,1,2,0]:
   t = [tr[*,i], tr[0,i]] & $
   ; Connect triangles:
   PLOTS, x[t], y[t]
ENDFOR

; The default size for the return value of trigrid. xtemp should be
; the same type as Z. xtemp provides temporary space for trigrid:
xtemp=FLTARR(51,51)
xtemp = TRIGRID(x, y, z, INPUT = xtemp, tr)

; Show linear surface:
SURFACE, xtemp, TITLE='Linear surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, /QUINTIC)

; Show smooth quintic surface:
SURFACE, xtemp, TITLE='Smooth Quintic surface', CHARSIZE=2
in=' '
READ,"Press enter",in
xtemp = TRIGRID(x, y, z, tr, INPUT = xtemp, EXTRA = b)

; Show smooth extrapolated surface:
SURFACE, xtemp, TITLE='Smooth Extrapolated surface', CHARSIZE=2
in=' '
READ,"Press enter",in
END
```

## Example 4

The XOUT and YOUT keywords allow you to obtain an irregular interval from the TRIGRID routine. This example creates an irregularly-gridded dataset of a Gaussian surface. A grid is formed from these points with the TRIANGULATE and TRIGRID routines. The inputs to the XOUT and YOUT keywords are determined at random to produce an irregular interval. These inputs are sorted before setting them to XOUT and YOUT because these keywords require monotonically ascending or descending

values. The lines of the resulting surface are spaced at the irregular intervals provided by the settings of the XOUT and YOUT keywords.

```
PRO GriddingIrregularIntervals

; Make 100 normal x, y points:
x = RANDOMN(seed, 100)
y = RANDOMN(seed, 100)
PRINT, MIN(x), MAX(x)
PRINT, MIN(y), MAX(y)

; Make a Gaussian surface:
z = EXP(-(x^2 + y^2))

; Obtain triangulation:
TRIANGULATE, x, y, triangles, boundary

; Create random x values.  These values will be used to
; form the x locations of the resulting grid.
gridX = RANDOMN(seed, 30)
; Sort x values. Sorted values are required for the XOUT
; keyword.
sortX = UNIQ(gridX, SORT(gridX))
gridX = gridX[sortX]
; Output sorted x values to be used with the XOUT
; keyword.
PRINT, 'gridX:'
PRINT, gridX

; Create random y values.  These values will be used to
; form the y locations of the resulting grid.
gridY = RANDOMN(seed, 30)
; Sort y values. Sorted values are required for the YOUT
; keyword.
sortY = UNIQ(gridY, SORT(gridY))
gridY = gridY[sortY]
; Output sorted y values to be used with the YOUT
; keyword.
PRINT, 'gridY:'
PRINT, gridY

; Derive grid of initial values.  The location of the
; resulting grid points are the inputs to the XOUT and
; YOUT keywords.
grid = TRIGRID(x, y, z, triangles, XOUT = gridX, $
   YOUT = gridY, EXTRAPOLATE = boundary)
```

```
; Display resulting grid.  The grid lines are not
; at regular intervals because of the randomness of the
; inputs to the XOUT and YOUT keywords.
SURFACE, grid, gridX, gridY, /XSTYLE, /YSTYLE

END

# TRIQL

The TRIQL procedure uses the QL algorithm with implicit shifts to determine the eigenvalues and eigenvectors of a real, symmetric, tridiagonal array. The routine TRIRED can be used to reduce a real, symmetric array to the tridiagonal form suitable for input to this procedure.

TRIQL is based on the routine `tqli` described in section 11.3 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

**Note**

If you are working with complex inputs, instead use the LA_TRIQL procedure.

## Syntax

TRIQL, *D*, *E*, *A* [, /DOUBLE]

## Arguments

### D

On input, this argument should be an *n*-element vector containing the diagonal elements of the array being analyzed. On output, *D* contains the eigenvalues.

### E

An *n*-element vector containing the off-diagonal elements of the array. $E_0$ is arbitrary. On output, this parameter is destroyed.

### A

A named variable that returns the *n* eigenvectors. If the eigenvectors of a tridiagonal array are desired, *A* should be input as an identity array. If the eigenvectors of an array that has been reduced by TRIRED are desired, *A* is input as the array *Q* output by TRIRED.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

# Examples

To compute eigenvalues and eigenvectors of a real, symmetric, tridiagonal array, begin with an array A representing a symmetric array:

```
; Create the array A:
A = [[ 3.0,  1.0, -4.0], $
    [ 1.0,  3.0, -4.0], $
    [-4.0, -4.0,  8.0]]

; Compute the tridiagonal form of A:
TRIRED, A, D, E

; Compute the eigenvalues (returned in vector D) and the
; eigenvectors (returned in the rows of the array A):
TRIQL, D, E, A

; Print eigenvalues:
PRINT, 'Eigenvalues:'
PRINT, D

; Print eigenvectors:
PRINT, 'Eigenvectors:'
PRINT, A
```

IDL prints:

```
Eigenvalues:
  2.00000  4.76837e-7  12.0000

Eigenvectors:
  0.707107  -0.707107   0.00000
 -0.577350  -0.577350  -0.577350
 -0.408248  -0.408248   0.816497
```

The exact eigenvalues are:

```
[2.0, 0.0, 12.0]
```

The exact eigenvectors are:

```
[ 1.0/sqrt(2.0), -1.0/sqrt(2.0), 0.0/sqrt(2.0)],
[-1.0/sqrt(3.0), -1.0/sqrt(3.0), -1.0/sqrt(3.0)],
[-1.0/sqrt(6.0), -1.0/sqrt(6.0), 2.0/sqrt(6.0)]
```

# TRIRED

The TRIRED procedure uses Householder's method to reduce a real, symmetric array to tridiagonal form.

TRIRED is based on the routine `tred2` described in section 11.2 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

**Note**

If you are working with complex inputs, instead use the LA_TRIRED procedure.

## Syntax

TRIRED, *A*, *D*, *E* [, /DOUBLE]

## Arguments

### A

An *n* by *n* real, symmetric array that is replaced, on exit, by the orthogonal array *Q* effecting the transformation. The routine TRIQL can use this result to find the eigenvectors of the array *A*.

### D

An *n*-element output vector containing the diagonal elements of the tridiagonal array.

### E

An *n*-element output vector containing the off-diagonal elements.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

See the description of TRIQL for an example using this function.

# TRISOL

The TRISOL function solves tridiagonal systems of linear equations that have the form: $A^T U = R$

**Note**

Because IDL subscripts are in column-row order, the equation above is written $A^T U = R$ rather than $AU = R$. The result *U* is a vector of length *n* whose type is identical to *A*.

TRISOL is based on the routine `tridag` described in section 2.4 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

**Note**

If you are working with complex inputs, instead use the LA_TRISOL procedure.

## Syntax

*Result* = TRISOL( *A*, *B*, *C*, *R* [, /DOUBLE] )

## Return Value

Returns a vector containing the solutions.

## Arguments

### A

A vector of length *n* containing the *n*-1 sub-diagonal elements of $A^T$. The first element of *A*, $A_0$, is ignored.

### B

An *n*-element vector containing the main diagonal elements of $A^T$.

### C

An *n*-element vector containing the *n*-1 super-diagonal elements of $A^T$. The last element of *C*, $C_{n-1}$, is ignored.

### R

An *n*-element vector containing the right hand side of the linear system $A^T U = R$.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Example

To solve a tridiagonal linear system, begin with an array representing a real tridiagonal linear system. (Note that only three vectors need be specified; there is no need to enter the entire array shown.)

$$\begin{bmatrix} -4.0 & 1.0 & 0.0 & 0.0 \\ 2.0 & -4.0 & 1.0 & 0.0 \\ 0.0 & 2.0 & -4.0 & 1.0 \\ 0.0 & 0.0 & 2.0 & -4.0 \end{bmatrix}$$

```
; Define a vector A containing the sub-diagonal elements with a
; leading 0.0 element:
A = [0.0, 2.0, 2.0, 2.0]

; Define B containing the main diagonal elements:
B = [-4.0, -4.0, -4.0, -4.0]

; Define C containing the super-diagonal elements with a trailing
; 0.0 element:
C = [1.0, 1.0, 1.0, 0.0]

; Define the right-hand side vector:
R = [6.0, -8.0, -5.0, 8.0]

; Compute the solution and print:
result = TRISOL(A, B, C, R)
PRINT, result
```

IDL prints:

```
-1.00000  2.00000  2.00000  -1.00000
```

The exact solution vector is [-1.0, 2.0, 2.0, -1.0].

# TRUNCATE_LUN

The TRUNCATE_LUN procedure truncates the contents of a file (which must be open for write access) at the current position of the file pointer. After this operation, all data before the current file pointer remains intact, and all data following the file pointer are gone. The position of the current file pointer is not altered.

## Syntax

TRUNCATE_LUN, *Unit*$_1$, ..., *Unit*$_n$

## Arguments

### Unit$_n$

Scalar or array variables containing the logical file unit numbers of the open files to be truncated.

## Keywords

None.

## Examples

### Example 1

Truncate the entire contents of an existing file:

```
OPENU, unit, 'baddata.dat', /GET_LUN
TRUNCATE_LUN, unit
FREE_LUN, unit
```

### Example 2

Given an existing file of 10,000 bytes, throw away the final 5,000 bytes, and then write an additional 2,000 byte array in their place. The resulting file will be 7,000 bytes in length.

```
OPENU, unit, 'mydata.dat', /GET_LUN
POINT_LUN, unit, 5000
TRUNCATE_LUN, unit
WRITEU, unit, BYTARR(2000)
FREE_LUN, unit
```

## Version History

Introduced: 5.6

# TS_COEF

The TS_COEF function computes the coefficients $\phi_1$, $\phi_2$, ... , $\phi_P$ used in a *P*-th order autoregressive time-series forecasting model. This routine is written in the IDL language. Its source code can be found in the file `ts_coef.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = TS_COEF( *X*, *P* [, /DOUBLE] [, MSE=*variable*] )

## Return Value

Returns a *P*-element vector whose type is identical to *X*.

## Arguments

### X

An *n*-element single- or double-precision floating-point vector containing time-series samples.

### P

An integer or long integer scalar that specifies the number of coefficients to be computed.

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### MSE

Set this keyword to a named variable that will contain the mean square error of the *P*-th order autoregressive model.

## Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]
; Compute the coefficients of a 5th order autoregressive model:
PRINT, TS_COEF(X, 5)
```

IDL prints:

```
1.30168    -0.111783    -0.224527     0.267629    -0.233363
```

## Version History

TS_FCAST

# TS_DIFF

The TS_DIFF function recursively computes the forward differences of an *n*-element time-series *k* times. This routine is written in the IDL language. Its source code can be found in the file `ts_diff.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = TS_DIFF( *X*, *K* [, /DOUBLE] )

## Return Value

The result is an *n*-element differenced time-series with its last *k* elements as zeros.

## Arguments

### X

An *n*-element integer, single- or double-precision floating-point vector containing time-series samples.

### K

A positive integer or long integer scalar that specifies the number of times *X* is to be differenced. *K* must be in the interval [1, N_ELEMENTS(*X*) - 1].

## Keywords

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## Examples

```
; Define an n-element vector of time-series samples:
X = [389, 345, 303, 362, 412, 356, 325, 375, $
     410, 350, 310, 388, 399, 362, 325, 382, $
     399, 382, 318, 385, 437, 357, 310, 391]
; Compute the second forward differences of X:
PRINT, TS_DIFF(X, 2)
```

IDL prints:

```
     2  101   -9 -106   25   81  -15  -95   20
   118  -67  -48    0   94  -40  -34  -47  131
   -15 -132   33  128    0    0
```

## Version History

Introduced: 4.0

## See Also

SMOOTH, TS_FCAST

# TS_FCAST

The TS_FCAST function computes future or past values of a stationary time-series using a *P*-th order autoregressive model.

A *P*-th order autoregressive model relates a forecasted value $x_t$ of the time series $X = [x_0, x_1, x_2, \ldots, x_{t-1}]$, as a linear combination of *P* past values.

$$x_t = \phi_1 x_{t-1} + \phi_2 x_{t-2} + \ldots + \phi_P x_{t-P} + w_t$$

The coefficients $\phi_1, \phi_2, \ldots, \phi_P$ are calculated such that they minimize the uncorrelated random error terms, *wt*.

This routine is written in the IDL language. Its source code can be found in the file `ts_fcast.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = TS_FCAST( *X*, *P*, *Nvalues* [, /BACKCAST] [, /DOUBLE] )

## Return Value

The result is an *Nvalues*-element vector whose type is identical to *X*.

## Arguments

### X

An *n*-element single- or double-precision floating-point vector containing time-series samples.

### P

An integer or long integer scalar that specifies the number of actual time-series values to be used in the forecast. In general, a larger number of values results in a more accurate forecast.

### Nvalues

An integer or long integer scalar that specifies the number of future or past values to be computed.

# Keywords

## BACKCAST

Set this keyword to produce past values (backward forecasts or “backcasts”)

## DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

# Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99, $
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31, $
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute and print five future values of the time-series using ten
; time-series values:
PRINT, TS_FCAST(X, 10, 5)

; Compute five past values of the time-series using ten time-series
;values:
PRINT, TS_FCAST(X, 10, 5, /BACKCAST)
```

IDL prints:

```
4.65870      4.58380      4.50030      4.48828      4.46971
6.94862      6.91103      6.86297      6.77826      6.70282
```

# Version History

Introduced: 4.0

# See Also

A_CORRELATE, COMFIT, CURVEFIT, SMOOTH, TS_COEF, TS_DIFF

# TS_SMOOTH

The TS_SMOOTH function computes central, backward, or forward moving averages of an *n*-element time-series. Autoregressive forecasting and backcasting are used to extrapolate the time-series and compute a moving average for each point.

**Note**

Central moving averages require *Nvalues*/2 forecasts and *Nvalues*/2 backcasts. Backward moving averages require *Nvalues*-1 backcasts. Forward moving averages require *Nvalues*-1 forecasts.

This routine is written in the IDL language. Its source code can be found in the file `ts_smooth.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = TS_SMOOTH( *X*, *Nvalues* [, /BACKWARD] [, /DOUBLE] [, /FORWARD] [, ORDER=*value*] )

## Return Value

The result is an *n*-element vector of the same data type as the input vector.

## Arguments

### X

An *n*-element single- or double-precision floating-point vector containing time-series samples. Note that *n* must be greater than or equal to 11.

### Nvalues

A scalar of type integer or long integer that specifies the number of time-series values used to compute each moving-average. If central-moving averages are computed (the default), this parameter must be an odd integer greater than or equal to three.

# Keywords

## BACKWARD

Set this keyword to compute backward-moving averages. If BACKWARD is set, the *Nvalues* argument must be an integer greater than one.

## DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

## FORWARD

Set this keyword to compute forward-moving averages. If FORWARD is set, the *Nvalues* argument must be an integer greater than one.

## ORDER

An integer or long-integer scalar that specifies the order of the autoregressive model used to compute the forecasts and backcasts of the time-series. By default, a time-series with a length between 11 and 219 elements will use an autoregressive model with an order of 10. A time-series with a length greater than 219 will use an autoregressive model with an order equal to 5% of its length. The ORDER keyword is used to override this default.

# Examples

```
; Define an n-element vector of time-series samples:
X = [6.63, 6.59, 6.46, 6.49, 6.45, 6.41, 6.38, 6.26, 6.09, 5.99,$
     5.92, 5.93, 5.83, 5.82, 5.95, 5.91, 5.81, 5.64, 5.51, 5.31,$
     5.36, 5.17, 5.07, 4.97, 5.00, 5.01, 4.85, 4.79, 4.73, 4.76]

; Compute the 11-point central-moving-averages of the time-series:
PRINT, TS_SMOOTH(X, 11)
```

IDL prints:

```
6.65761 6.60592 6.54673 6.47646 6.40480 6.33364
6.27000 6.20091 6.14273 6.09364 6.04455 5.99000
5.92273 5.85455 5.78364 5.72636 5.65818 5.58000
5.50182 5.42727 5.34182 5.24545 5.15273 5.07000
5.00182 4.94261 4.87205 4.81116 4.75828 4.71280
```

# Version History

Introduced: 5.0

SMOOTH, TS_DIFF, TS_FCAST

# TV

The TV procedure displays images on the image display without scaling the intensity. To display an image with scaling, use the TVSCL procedure.

**Note**

To display a TrueColor image (an image with 16, 24, or 32 bits per pixel) you must specify the TRUE keyword.

While the TV procedure does not *scale* the intensity of an image, it does convert the input image data to byte type. Values outside the range [0,255] are "wrapped" during the conversion. In addition, for displays with less than 256 colors, elements of the input image with values between !D.TABLE_SIZE and 255 will be displayed using the color index !D.TABLE_SIZE-1.

## Syntax

TV, *Image* [, *Position*]

or

TV, *Image* [, *X*, *Y* [, *Channel*]]

**Keywords:** [, /CENTIMETERS | , /INCHES] [, /ORDER] [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=*value*] [, YSIZE=*value*]

**Graphics Keywords:** [, CHANNEL=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, /T3D | Z=*value*]

## Arguments

### Image

A vector or two-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

### X, Y

If *X* and *Y* are present, they specify the lower-left coordinate of the displayed image, relative to the lower-left corner of the screen.

## Position

An integer specifying the position for *Image* within the graphics window. Image positions run from the top left of the screen to the bottom right. If a position number is used instead of *X* and *Y*, the position of the image is calculated from the dimensions of the image as follows (integer arithmetic is used).

$$\text{Xsize, Ysize} = \text{Size of display or window}$$

$$\text{Xdim, Ydim} = \text{Dimensions of image to be displayed}$$

$$N_x = \frac{\text{Xsize}}{\text{Ydim}} = \text{Images across screen}$$

$$X = \text{Xdim}\,\text{Position}_{\text{modulo}\,N_x} = \text{Starting X}$$

$$Y = \text{Ysize} - \text{Ydim}\left[1 + \frac{\text{Position}}{N_x}\right] = \text{Starting Y}$$

For example, when displaying 128 by 128 images on a 512 by 512 display, the position numbers run from 0 to 15 as follows:

| | | | |
|---|---|---|---|
| 0 | 1 | 2 | 3 |
| 4 | 5 | 6 | 7 |
| 8 | 9 | 10 | 11 |
| 12 | 13 | 14 | 15 |

**Note**

When using a device with scalable pixels (e.g., PostScript), the XSIZE and YSIZE keywords should also be used.

## Channel

The memory channel to be written to. The *Channel* argument is identical to the CHANNEL graphics keyword.

# Keywords

## CENTIMETERS

Set this keyword to indicate that the *X*, *Y*, *Xsize*, *Ysize*, and *Z* arguments are given in centimeters from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

## INCHES

Set this keyword to indicate that all position and size values are given in inches from the origin. This system is useful when dealing with devices, such as PostScript printers, that do not provide a direct relationship between image pixels and the size of the resulting image.

## ORDER

If specified, ORDER overrides the current setting of the !ORDER system variable for the current image only. If set, the image is drawn from the top down instead of the normal bottom up.

## TRUE

Set this keyword to a nonzero value to indicate that a TrueColor (16-, 24-, or 32-bit) image is to be displayed. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The image parameter must have three dimensions, one of which must be equal to three. For example, set TRUE to 1 to display an image that is pixel interleaved and has dimensions of (3, *m*, *n*). Specify 2 for row-interleaved images, of size (*m*, 3, *n*), and 3 for band-interleaved images of the form (*m*, *n*, 3).

See “TrueColor Images” on page 3842 for an example using this keyword to write 24-bit images to the PostScript device.

## WORDS

Set this keyword to indicate that words (short integers) instead of 8-bit bytes are to be transferred to the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the *Image* parameter is converted to short integer type, if necessary, and then written to the display.

### XSIZE

The width of the resulting image. On devices with scalable pixel size (such as PostScript), if XSIZE is specified the image will be scaled to fit the specified width. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

### YSIZE

The height of the resulting image. On devices with scalable pixel size (such as PostScript), if YSIZE is specified the image will be scaled to fit the specified height. If neither XSIZE nor YSIZE is specified, the image will be scaled to fill the plotting area, while preserving the image's aspect ratio. This keyword is ignored by pixel-based devices that are unable to change the size of their pixels.

### Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of graphics and plotting keywords not listed above. CHANNEL, DATA, DEVICE, NORMAL, T3D, Z.

## Examples

```
; Create and display a simple image:
D = BYTSCL(DIST(256)) & TV, D

; Erase the screen:
ERASE

; Use the position parameter to display a number of images in the
; same window.
; Display the image in the upper left corner.
TV, D, 0

; Display another copy of the image in the next position:
TV, D, 1
```

## Version History

Introduced: Original

# TVCRS

The TVCRS procedure manipulates the display device cursor. The initial state of the cursor is device dependent. Call TVCRS with one argument to enable or disable the cursor. Call TVCRS with two parameters to enable the cursor and place it on pixel location *(X, Y)*.

## Syntax

TVCRS [, *ON_OFF*]

or

TVCRS [, *X*, *Y*]

**Keywords:** [, /CENTIMETERS | , /INCHES] [, /HIDE_CURSOR]

**Graphics Keywords:** [, /DATA | , /DEVICE | , /NORMAL] [, /T3D | Z=*value*]

## Arguments

### ON_OFF

This argument specifies whether the cursor should be on or off. If this argument is present and nonzero, the cursor is enabled. If *ON_OFF* is zero or no parameters are specified, the cursor is turned off.

### X

The column to which the cursor is set.

### Y

The row to which the cursor is set.

## Keywords

### CENTIMETERS

Set this keyword to cause X and Y to be interpreted as centimeters, based on the current device resolution.

### INCHES

Set this keyword to cause X and Y to be interpreted as inches, based on the current device resolution.

### HIDE_CURSOR

By default, disabling the cursor works differently for window systems than for other devices. For window systems, the cursor is restored to the standard cursor used for non-IDL windows (and remains visible), while for other devices it is completely blanked out. If the HIDE keyword is set, disabling the cursor causes it to always be blanked out.

### Graphics Keywords Accepted

See Appendix B, “Graphics Keywords” for the description of graphics and plotting keywords not listed above. DATA, DEVICE, NORMAL, T3D, Z.

## Examples

To enable the graphics cursor and position it at device coordinate (100, 100), enter:

```
TVCRS, 100, 100
```

To position the cursor at data coordinate (0.5, 3.2), enter:

```
TVCRS, 0.5, 3.2, /DATA
```

## Version History

Introduced: Original

CURSOR, RDPIX

# TVLCT

The TVLCT procedure loads the display color translation tables from the specified variables. Although IDL uses the RGB color system internally, color tables can be specified to TVLCT using any of the following color systems: RGB (Red, Green, Blue), HLS (Hue, Lightness, Saturation), and HSV (Hue, Saturation, Value). Alpha values may also be used when using the second form of the command. The type and meaning of each argument is dependent upon the color system selected, as described below. Color arguments can be either scalar or vector expressions. If no color-system keywords are present, the RGB color system is used.

## Syntax

TVLCT, $V_1$, $V_2$, $V_3$ [, *Start*] [, /GET] [, /HLS | , /HSV]

or

TVLCT, *V* [, *Start*] [, /GET] [, /HLS | , /HSV]

## Arguments

TVLCT will accept either three *n*-element vectors ($V_1$, $V_2$, and $V_3$) or a single *n*-by-3 array (*V*) as an argument. The vectors (or columns of the array) have different meanings depending on the color system chosen. If an array *V* is specified, *V*[*,0] is the same as $V_1$, *V*[*,1] is the same as $V_2$, *V*[*,2] is the same as $V_3$. In the description below, we assume that three vectors, $V_1$, $V_2$, and $V_3$ are specified.

The $V_1$, $V_2$, and $V_3$ arguments have different meanings depending upon which color system they represent.

### R, G, B Color System

The parameters $V_1$, $V_2$, and $V_3$ contain the Red, Green, and Blue values, respectively. Values are interpreted as integers in the range 0 (lowest intensity) to 255 (highest intensity). The parameters can be scalars or vectors of up to 256 elements. By default, the three arguments are assumed to be R, G, and B values.

### H, L, S Color System

Parameters $V_1$, $V_2$, and $V_3$ contain the Hue, Lightness, and Saturation values respectively. All parameters are floating-point. Hue is expressed in degrees and is reduced modulo 360. $V_2$ (lightness) and $V_3$ (saturation) and can range from 0 to 1.0. Set the HLS keyword to have the arguments interpreted this way.

### H, S, V Color System

Parameters $V_1$, $V_2$, and $V_3$ contain values for Hue, Saturation, and Value (similar to intensity). All parameters are floating-point. Hue is in degrees. The Saturation and Value can range from 0 to 1.0. Set the HSV keyword to have the arguments interpreted this way.

### Start

An integer value that specifies the starting point in the color translation table into which the color intensities are loaded. If this argument is not specified, a value of zero is used, causing the tables to be loaded starting at the first element of the translation tables.

## Keywords

### GET

Set this keyword to return the RGB values from the internal color tables into the $V_1$, $V_2$, and $V_3$ parameters. For example, the statements:

```
TVLCT, H, S, V, /HSV
TVLCT, R, G, B, /GET
```

load a color table based in the HSV system, and then read the equivalent RGB values into the variables R, G, and B.

### HLS

Set this keyword to indicate that the parameters specify color using the HLS color system.

### HSV

Set this keyword to indicate that the parameters specify color using the HSV color system.

## Examples

```
; Initialize display.
DEVICE, DECOMPOSED = 0

; Create a set of R, G, and B colormap vectors:
R = BYTSCL(SIN(FINDGEN(256)))
G = BYTSCL(COS(FINDGEN(256)))
B = BINDGEN(256)
```

```
; Load these vectors into the color table:
TVLCT, R, G, B

; Display an image to see the effect of the new color table:
TVSCL, DIST(400)
```

LOADCT, XLOADCT, XPALETTE

# TVRD

The TVRD function returns the contents of the specified rectangular portion of the current graphics window or device. ($X_0$, $Y_0$) is the coordinate of the lower left corner of the area to be read and $N_x$, $N_y$ is the size of the rectangle in columns and rows. The result is a byte array of dimensions $N_x$ by $N_y$. All parameters are optional. If no arguments are supplied, the entire display device area is read.

### Important Note about TVRD and Backing Store

On some systems, when backing store is provided by the window system (the RETAIN keyword to DEVICE or WINDOW is set to 1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (set the RETAIN keyword to 2) ensures that the window contents will be read properly. More detailed notes about TVRD and the X Window system can be found below in "Unexpected Results Using TVRD with X Windows" on page 2053.

**Note**

When using TVRD on 16-bit TrueColor displays only 5 or 6 bits of pixel data are stored for each color channel. Using TVRD on these displays returns channel data where only the high 5 or 6 bits are significant; the other bits are indeterminate.

## Syntax

*Result* = TVRD( [$X_0$ [, $Y_0$ [, $N_x$ [, $N_y$ [, *Channel*]]]]] [, CHANNEL=*value*] [, /ORDER] [, TRUE={1 | 2 | 3}] [, /WORDS] )

## Return Value

Returns a byte array of the specified dimensions.

## Arguments

### $X_0$

The starting column of data to read. The default is 0.

### $Y_0$

The starting row of data to read. The default is 0.

### $N_x$

The number of columns to read. The default is the width of the display device or window less $X_0$.

### $N_y$

The number of rows to read. The default is the height of the display device or window less $Y_0$.

### Channel

The memory channel to be read. If not specified, this argument is assumed to be zero. This parameter is ignored on display systems that have only one memory channel.

## Keywords

### CHANNEL

The memory channel to be read. The CHANNEL keyword is identical to the optional *Channel* argument.

**Note**

If the display is a 24-bit display, and both the CHANNEL and TRUE parameters are absent, the maximum RGB value in each pixel is returned.

### ORDER

Set this keyword to override the current setting of the !ORDER system variable for the current image only. If set, it causes the image to be read from the top down instead of the normal bottom up.

### TRUE

If this keyword is present, it indicates that a TrueColor image is to be read, if the display is capable. The value assigned to TRUE specifies the index of the dimension over which color is interleaved. The result is an (3, $n_x$, $n_y$) pixel-interleaved array if TRUE is 1; or an ($n_x$, 3, $n_y$) line-interleaved array if TRUE is 2; or an ($n_x$, $n_y$, 3) image-interleaved array if TRUE is 3.

### WORDS

Set this keyword to indicate that words are to be transferred from the device. This keyword is valid only when using devices that can transfer 16-bit pixels. The normal transfer uses 8-bit pixels. If this keyword is set, the function result is an integer array.

## Unexpected Results Using TVRD with X Windows

When using TVRD with the X Windows graphics device, there are two unexpected behaviors that can be confusing to users:

- When reading from a window that is obscured by another window (i.e., the target window has another window “on top” or “in front” of it), TVRD may return the contents of the window in front as part of the image contained in the target window.
- When reading from an iconified window, the X server may return a stream of “BadMatch” protocol events.

IDL uses the Xlib function `XGetSubImage()` to implement TVRD. The following quote is from the documentation for XGetSubImage() found in *The X Window System* by Robert W. Scheifler and James Gettys, Second Edition, page 174. It explains the reasons for the behaviors described above:

“If the drawable is a window, the window must be viewable, and it must be the case that if there were no... overlapping windows, the specified rectangle of the window would be fully visible on the screen, ... or a BadMatch error results. If the window has backing-store, then the backing-store contents are returned for regions of the window that are obscured... If the window does not have backing-store, the returned contents of such obscured regions are undefined.”

Hence, the first behavior is caused by attempting to use TVRD on an obscured window that does not have backing store provided by the X server. The result in this case is undefined, meaning that the different servers can produce entirely different results. Many servers simply return the image of the obscuring window.

The second behavior is caused by attempting to read from a non-viewable (i.e., unmapped) window. Although IDL could refuse to allow TVRD to work with unmapped windows, some X servers return valid and useful results. Therefore, TVRD is allowed to attempt to read from unmapped windows.

Both of these behavior problems can be solved by using one of the following methods:

- Always make sure that your target window is mapped and is not obscured before using TVRD on it. The following IDL command can be used:

```
WSET, Window_Index
```

- Make IDL provide backing store (rather than the window system) by setting the RETAIN keyword to DEVICE or WINDOW equal to 2.

For a full description of backing store, see “Backing Store” on page 3824. Note that under X Windows, backing store is a request that may or may not be honored by the X server. Many servers will honor backing store for 8-bit visuals but ignore them for 24-bit visuals because they require three times as much memory.

## Examples

```
; Read the entire contents of the current display device into the
; variable T:
T = TVRD()
```

RDPIX, TV, WINDOW

# TVSCL

The TVSCL procedure scales the intensity values of *Image* into the range of the image display and outputs the data to the image display at the specified location. The array is scaled so the minimum data value becomes 0 and the maximum value becomes the maximum number of available colors (held in the system variable !D.TABLE_SIZE) as follows:

$$\text{Output} = (\text{!D.TABLE\_SIZE} - 1)\frac{\text{Data} - \text{Data}_{\text{min}}}{\text{Data}_{\text{max}} - \text{Data}_{\text{min}}}$$

where the maximum and minimum are found by scanning the array. The parameters and keywords of the TVSCL procedure are identical to those accepted by the TV procedure. For additional information about each parameter, consult the description of TV.

## Syntax

TVSCL, *Image* [, *Position*]

or

TVSCL, *Image* [, *X*, *Y* [, *Channel*]]

**Keywords:** [, /CENTIMETERS | , /INCHES] [, /NAN] [, /ORDER] [, TOP=*value*] [, TRUE={1 | 2 | 3}] [, /WORDS] [, XSIZE=*value*] [, YSIZE=*value*]

**Graphics Keywords:** [, CHANNEL=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, /T3D | Z=*value*]

## Arguments

### Image

A two-dimensional array to be displayed as an image. If this argument is not already of byte type, it is converted prior to use.

### X, Y

If *X* and *Y* are present, they specify the lower left coordinate of the displayed image.

### Position

Image position. See the discussion of the TV procedure for a full description.

### Channel

The memory channel to be written. This argument is assumed to be zero if not specified. This parameter is ignored on display systems that have only one memory channel.

## Keywords

TVSCL accepts all of the keywords accepted by the TV routine. See "TV" on page 2042. In addition, there are two unique keywords:

### NAN

Set this keyword to cause TVSCL to treat elements of *Image* that are not numbers (that is, elements that have the special floating-point values *Infinity* or *NaN*) as missing data, and display them using color index 0 (zero). Note that color index 0 is also used to display elements that have the minimum value in the *Image* array.

### TOP

The maximum value of the scaled result. If TOP is not specified, !D.TABLE_SIZE-1 is used. Note that the minimum value of the scaled result is always 0.

### Graphics Keywords Accepted

See Appendix B, "Graphics Keywords" for the description of graphics and plotting keywords not listed above. CHANNEL, DATA, DEVICE, NORMAL, T3D, Z.

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

## Examples

Display a floating-point array as an image using the TV command:

```
TV, DIST(200)
```

Note that the image is not easily visible because the values in the array have not been scaled into the full range of display values. Now display the image with the TVSCL command by entering:

```
TVSCL, DIST(200)
```

Notice how much brighter the image appears.

# UINDGEN

The UINDGEN function creates an unsigned integer array. Each element of the array is set to the value of its one-dimensional subscript.

## Syntax

*Result* = UINDGEN($D_1$ [, ..., $D_8$])

## Return Value

Returns an unsigned integer array of the specified dimensions.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

## Keywords

### Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

## Examples

To create UI, a 10-element by 10-element 16-bit array where each element is set to the value of its one-dimensional subscript, enter:

```
UI = UINDGEN(10, 10)
```

## Version History

Introduced: 5.2

# UINT

The UINT function returns a result equal to *Expression* converted to unsigned integer type.

## Syntax

*Result* = UINT( *Expression[, Offset [, $D_1$ [, ..., $D_8$]]]* )

## Return Value

Returns the specified dimensions of the given expression as an unsigned integer type.

## Arguments

### Expression

The expression to be converted to unsigned integer.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned integer data. See the description in Chapter 3, “Constants and Variables” in the *Building IDL Applications* manual for details.

### $D_i$

When extracting fields of data, the $D_i$ arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The $D_i$ arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

# Keywords

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

# Examples

If A contains the floating-point value 32000.0, it can converted to an unsigned integer and stored in the variable B by entering:

```
B = UINT(A)
```

# Version History

Introduced: 5.2

# See Also

# UINTARR

The UINTARR function creates an unsigned integer vector or array.

## Syntax

*Result* = UINTARR( $D_1$ *[, ..., $D_8$]* [, /NOZERO] )

## Return Value

Returns an unsigned integer vector or array of the specified dimensions.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### NOZERO

Normally, UINTARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and UINTARR executes faster.

## Examples

To create L, a 100-element, unsigned integer vector with each element set to 0, enter:

```
L = UINTARR(100)
```

## Version History

Introduced: 5.2

# UL64INDGEN

The UL64INDGEN function returns an unsigned 64-bit integer array with the specified dimensions. Each element of the array is set to the value of its one-dimensional subscript.

## Syntax

*Result* = UL64INDGEN($D_1$ [, ..., $D_8$])

## Return Value

Returns the specified unsigned integer array.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified. If the dimension arguments are not integer values, IDL will convert them to integer values before creating the new array.

# ULON64ARR

The ULON64ARR function returns an unsigned 64-bit integer vector or array.

## Syntax

*Result* = ULON64ARR( $D_1$ *[, ..., $D_8$]* [, /NOZERO] )

## Return Value

Returns a vector or array of the specified dimensions.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### NOZERO

Normally, ULON64ARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and ULON64ARR executes faster.

## Examples

To create L, a 100-element, unsigned 64-bit vector with each element set to 0, enter:

```
L = ULON64ARR(100)
```

## Version History

Introduced: 5.2

# ULONARR

The ULONARR function returns an unsigned longword integer vector or array.

## Syntax

*Result* = ULONARR( $D_1$ *[*, ..., $D_8$*]* [, /NOZERO] )

## Return Value

Returns an unsigned longword integer array of the specified dimensions.

## Arguments

### $D_i$

Either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

## Keywords

### NOZERO

Normally, ULONARR sets every element of the result to zero. If NOZERO is set, this zeroing is not performed and ULONARR executes more quickly.

## Examples

To create L, a 100-element, unsigned longword vector with each element set to 0, enter:

```
L = ULONARR(100)
```

## Version History

Introduced: 5.2

# ULONG

The ULONG function returns a result equal to *Expression* converted to the unsigned longword integer type.

## Syntax

*Result* = ULONG( *Expression[, Offset [, $D_1$ [, ..., $D_8$]]]* )

## Return Value

Returns the specified dimensions of the given expression as an unsigned longword integer type.

## Arguments

### Expression

The expression to be converted to unsigned longword integer.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned longword integer data. See the description in Chapter 3, “Constants and Variables” in the *Building IDL Applications* manual for details.

### $D_i$

When extracting fields of data, the $D_i$ arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The $D_i$ arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

# Keywords

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

# Examples

If A contains the floating-point value 32000.0, it can converted to an unsigned longword integer and stored in the variable B by entering:

```
B = ULONG(A)
```

# Version History

Introduced: 5.2

# See Also

BYTE, COMPLEX, DCOMPLEX, DOUBLE, FIX, FLOAT, LONG, LONG64, STRING, UINT, ULONG64

# ULONG64

The ULONG64 function returns a result equal to *Expression* converted to the unsigned 64-bit integer type.

## Syntax

*Result* = ULONG64( *Expression[, Offset [, $D_1$ [, ..., $D_8$]]]* )

## Return Value

Returns the specified dimensions of the given expression as an unsigned 64-bit integer type.

## Arguments

### Expression

The expression to be converted to unsigned 64-bit integer.

### Offset

Offset from beginning of the *Expression* data area. Specifying this argument allows fields of data extracted from *Expression* to be treated as unsigned 64-bit integer data. See the description in Chapter 3, “Constants and Variables” in the *Building IDL Applications* manual for details.

### $D_i$

When extracting fields of data, the $D_i$ arguments specify the dimensions of the result. If no dimension arguments are given, the result is taken to be scalar.

The $D_i$ arguments can be either an array or a series of scalar expressions specifying the dimensions of the result. If a single argument is specified, it can be either a scalar expression or an array of up to eight elements. If multiple arguments are specified, they must all be scalar expressions. Up to eight dimensions can be specified.

When converting from a string argument, it is possible that the string does not contain a valid integer and no conversion is possible. The default action in such cases is to print a warning message and return 0. The ON_IOERROR procedure can be used to establish a statement to be jumped to in case of such errors.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

# Examples

If A contains the floating-point value 32000.0, it can converted to an unsigned 64-bit integer and stored in the variable B by entering:

```
B = ULONG64(A)
```

# Version History

Introduced: 5.2

# See Also

BYTE, COMPLEX, DCOMPLEX, DOUBLE, FIX, FLOAT, LONG, LONG64, STRING, UINT, ULONG

# UNIQ

The UNIQ function returns the subscripts of the unique elements in an array. Note that repeated elements must be adjacent in order to be found. This routine is intended to be used with the SORT function: see the examples below. This function was inspired by the UNIX `uniq(1)` command.

This routine is written in the IDL language. Its source code can be found in the file `uniq.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = UNIQ( *Array* [, *Index*] )

## Return Value

UNIQ returns an array of indices into the original array. Note that the index of the last element in each set of non-unique elements is returned. The following expression is a copy of the sorted array with duplicate adjacent elements removed:

*Array*`(UNIQ(`*Array*`))`

UNIQ returns 0 (zero) if the argument supplied is a scalar rather than an array.

## Arguments

### Array

The array to be scanned. For UNIQ to work properly, the array must be sorted into monotonic order unless the optional parameter *Idx* is supplied.

### Index

This optional parameter is an array of indices into *Array* that order the elements into monotonic order. That is, the expression:

*Array*`(`*Index*`)`

yields an array in which the elements of *Array* are rearranged into monotonic order. If the array is not already in monotonic order, use the command:

```
UNIQ(Array, SORT(Array))
```

## Examples

Find the unique elements of an unsorted array:

```
; Create an array:
array = [1, 2, 1, 2, 3, 4, 5, 6, 6, 5]

; Variable B holds an array containing the sorted, unique values in
; array:
b = array[UNIQ(array, SORT(array))]
PRINT, b
```

IDL prints

```
1    2    3    4    5    6
```

## Version History

Introduced: Pre 4.0

SORT, WHERE

# USERSYM

The USERSYM procedure is used to define the plotting symbol that marks points when the plotting symbol is set to plus or minus 8. Symbols can be drawn with vectors or can be filled. Symbols can be of any size and can have up to 50 vertices. See"Defining Your Own Plotting Symbols" in Chapter 17 of the *Using IDL* manual .

## Syntax

USERSYM, *X* [, *Y*] [, COLOR=*value*] [, /FILL] [, THICK=*value*]

## Arguments

### X, Y

The *X* and/or *Y* parameters define the vertices of the symbol as offsets from the data point in units of approximately the size of a character. In the case of a vector drawn symbol, the symbol is formed by connecting the vertices in order. If only one argument is specified, it must be a (2, *N*) array of vertices, with element [0, *i*] containing the X coordinate of the vertex, and element [1, *i*] containing the Y. If both arguments are provided, *X* contains only the X coordinates.

## Keywords

### COLOR

The color used to draw the symbols, or used to fill the polygon. The default color is the same as the line color.

### FILL

Set this keyword to fill the polygon defined by the vertices. If FILL is not set, lines are drawn connecting the vertices.

### THICK

The thickness of the lines used in drawing the symbol. The default thickness is 1.0.

## Examples

Make a large, diamond-shaped plotting symbol. Define the vectors of X values by entering:

```
X = [-6, 0, 6, 0, -6]
```

Define the vectors of Y values by entering:

```
Y = [0, 6, 0, -6, 0]
```

Now call USERSYM to create the new plotting symbol 8. Enter:

```
USERSYM, X, Y
```

Generate a simple plot to test the plotting symbol by entering:

```
PLOT, FINDGEN(20), PSYM = 8
```

PLOT

# VALUE_LOCATE

The VALUE_LOCATE function finds the intervals within a given monotonic vector that brackets a given set of one or more search values. This function is useful for interpolation and table-lookup, and is an adaptation of the locate() routine in Numerical Recipes. VALUE_LOCATE uses the bisection method to locate the interval.

## Syntax

*Result* = VALUE_LOCATE ( *Vector*, *Value* [, /L64 ] )

## Return Value

Each return value, *Result* [*i*], is an index, *j*, into *Vector*, corresponding to the interval into which the given *Value* [*i*] falls. The returned values are in the range $-1 \le j \le N-1$, where *N* is the number of elements in the input vector.

If *Vector* is monotonically increasing, the result *j* is:

if $j = -1$ *Value* [*i*] < *Vector* [0]

if $0 \le j < N-1$ *Vector* [*j*] ≤ *Value* [*i*] < *Vector* [*j*+1]

if $j = N-1$ *Vector* [*N*–1] ≤ *Value* [*i*]

If *Vector* is monotonically decreasing

if $j = -1$ *Vector* [*0*] ≤ *Value* [*i*]

if $0 \le j < N-1$ *Vector* [*j*+1] ≤ *Value* [*i*] < *Vector* [*j*]

if $j = N-1$ *Value* [*i*] < *Vector* [*N*–1]

## Arguments

### Vector

A vector of monotonically increasing or decreasing values. *Vector* may be of type string, or any numeric type except complex, and may not contain the value NaN (not-a-number).

### Value

The value for which the location of the intervals is to be computed. *Value* may be either a scalar or an array. The return value will contain the same number of elements as this parameter.

## Keywords

### L64

By default, the result of VALUE_LOCATE is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases.

**Note**

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

## Examples

```
; Define a vector of values.
vec = [2,5,8,10]

; Compute location of other values within that vector.
loc = VALUE_LOCATE(vec, [0,3,5,6,12])
PRINT, loc
```

IDL prints:

```
-1   0   1   1   3
```

## Version History

Introduced: 5.3

# VARIANCE

The VARIANCE function computes the statistical variance of an *n*-element vector.

## Syntax

*Result* = VARIANCE( *X* [, /DOUBLE] [, /NAN] )

## Return Value

Returns the floating-point or double-precision statistical variance of the input vector.

## Arguments

### X

An *n*-element, floating-point or double-precision vector.

## Keywords

### DOUBLE

If this keyword is set, VARIANCE performs its computations in double precision arithmetic and returns a double precision result. If this keyword is not set, the computations and result depend upon the type of the input data (integer and float data return float results, while double data returns double results).

### NAN

Set this keyword to cause the routine to check for occurrences of the IEEE floating-point value NaN in the input data. Elements with the value NaN are treated as missing data. (See "Special Floating-Point Values" in Chapter 18 of the *Building IDL Applications* manual for more information on IEEE floating-point values.)

## Examples

```
; Define the n-element vector of sample data:
x = [1, 1, 1, 2, 5]
; Compute the variance:
result = VARIANCE(x)
PRINT, result
```

IDL prints:

```
3.00000
```

# VECTOR_FIELD

The VECTOR_FIELD procedure is used to place colored, oriented vectors of specified length at each vertex in an input vertex array. The output can be sent directly to an IDLgrPolyline object. The generated display is generally referred to as a hedgehog display and is used to convey various aspects of a vector field.

## Syntax

VECTOR_FIELD, *Field*, *Outverts*, *Outconn* [, ANISOTROPY=*array*] [, SCALE=*value*] [, VERTICES=*array*]

## Arguments

### Field

Input vector field array. This can be a [3, *x*, *y*, *z*] array or a [2, *x*, *y*] array. The leading dimension is the vector quantity to be displayed.

### Outverts

Output vertex array ([3, *N*] or [2, *N*] array of floats). Useful if the routine is to be used with Direct Graphics or the user wants to manipulate the data directly.

### Outconn

Output polyline connectivity array to be applied to the output vertices.

## Keywords

### ANISOTROPY

Set this keyword to a two- or three-element array describing the distance between grid points in each dimension. The default value is [1.0, 1.0, 1.0] for three-dimensional data and [1.0, 1.0] for two-dimensional data.

### SCALE

Set this keyword to a scalar scaling factor. All vector lengths are multiplied by this value. The default is 1.0.

### VERTICES

Set this keyword to a [3, *n*] or [2, *n*] array of points. If this keyword is set, the vector field is interpolated at these points. The resulting interpolated vectors are displayed as line segments at these locations. If the keyword is not set, each spatial sample point in the input Field grid is used as the base point for a line segment.

## Version History

Introduced: 5.3

# VEL

The VEL procedure draws a velocity (flow) field with arrows following the field proportional in length to the field strength. Arrows are composed of a number of small segments that follow the streamlines.

This routine is written in the IDL language. Its source code can be found in the file `vel.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

VEL, *U*, *V* [, NVECS=*value*] [, XMAX= *value*{*xsize*/*ysize*}]
[, LENGTH=*value*{*longest*/*steps*}] [, NSTEPS=*value*] [, TITLE=*string*]

## Arguments

### U

The X component at each point of the vector field. *U* must be a 2-D array.

### V

The Y component at each point of the vector field. *V* must have the same dimensions as *U*.

## Keywords

### LENGTH

The length of each arrow line segment expressed as a fraction of the longest vector divided by the number of steps. The default is 0.1.

### NSTEPS

The number of shoots or line segments for each arrow. The default is 10.

### NVECS

The number of vectors (arrows) to draw. If this keyword is omitted, 200 vectors are drawn.

### TITLE

A string containing the title for the plot.

### XMAX

X axis size as a fraction of Y axis size. The default is 1.0. This argument is ignored when !P.MULTI is set.

## Examples

```
; Create a vector of X values:
X = DIST(20)

; Create a vector of Y values:
Y = SIN(X)*100

; Plot the vector field:
VEL, X, Y
```

## Version History

Introduced: Pre 4.0

FLOW3, PLOT_FIELD, VELOVECT

# VELOVECT

The VELOVECT procedure produces a two-dimensional velocity field plot. A directed arrow is drawn at each point showing the direction and magnitude of the field.

This routine is written in the IDL language. Its source code can be found in the file `velovect.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

VELOVECT, *U*, *V* [, *X*, *Y*] [, COLOR=*index*] [, MISSING=*value* [, /DOTS]] [, LENGTH=*value*] [, /OVERPLOT] [Also accepts all PLOT keywords]

## Arguments

### U

The X component of the two-dimensional field. *U* must be a two-dimensional array.

### V

The Y component of the two dimensional field. *V* must have the same dimensions as *U*.

### X

Optional abscissae values. *X* must be a vector with a length equal to the first dimension of *U* and *V*.

### Y

Optional ordinate values. *Y* must be a vector with a length equal to the second dimension of *U* and *V*.

## Keywords

**Note**

Keywords not described here are passed directly to the PLOT procedure and may be used to set options such as TITLE, POSITION, NOERASE, etc.

### COLOR

Set this keyword equal to the color index used for the plot.

### DOTS

Set this keyword to 1 to place a dot at each missing point. Set this keyword to 0 or omit it to draw nothing for missing points. Has effect only if MISSING is specified.

### LENGTH

Set this keyword equal to the length factor. The default of 1.0 makes the longest (*U*,*V*) vector the length of a cell.

### MISSING

Set this keyword equal to the missing data value. Vectors with a length greater than MISSING are ignored.

### OVERPLOT

Set this keyword to make VELOVECT “overplot”. That is, the current graphics screen is not erased, no axes are drawn, and the previously established scaling remains in effect.

### PLOT Keywords

In addition to the keywords described above, all other keywords accepted by the PLOT procedure are accepted by VELOVECT. See PLOT.

## Examples

```
; Create some random data:
U = RANDOMN(S, 20, 20)
V = RANDOMN(S, 20, 20)

; Plot the vector field:
VELOVECT, U, V

; Plot the field, using dots to represent vectors with values
; greater than 18:
VELOVECT, U, V, MISSING=18, /DOTS

; Plot with a title. Note that the XTITLE keyword is passed
; directly to the PLOT procedure:
VELOVECT, U, V, MISSING=18, /DOTS, XTITLE='Random Vectors'
```

## Version History

Introduced: Original

FLOW3, PLOT, PLOT_FIELD, VEL

# VERT_T3D

The VERT_T3D function transforms a 3-D array by a 4x4 transformation matrix. The 3-D points are typically an array of polygon vertices that were generated by SHADE_VOLUME or MESH_OBJ.

This routine is written in the IDL language. Its source code can be found in the file `vert_t3d.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = VERT_T3D( *Vertex_List* [, DOUBLE=*value*] [, MATRIX=*4x4_array*] [, /NO_COPY] [, /NO_DIVIDE [, SAVE_DIVIDE=*variable*]] )

## Return Value

Returns the single- or double-precision coordinates of the transformed array.

## Arguments

### Vertex_List

A 3 x *n* array of 3-D coordinates to transform.

## Keywords

### DOUBLE

Set this keyword to a nonzero value to indicate that the returned coordinates should be double-precision. If this keyword is not set, the default is to return single-precision coordinates (unless double-precision arguments are input, in which case the DOUBLE keyword is implied to be non-zero).

### MATRIX

The 4x4 transformation matrix to use. The default is to use the system viewing matrix (!P.T).

### NO_COPY

Normally, a copy of *Vertex_list* is transformed and the original *Vertex_list* is preserved. If NO_COPY is set, however, then the original *Vertex_List* will be undefined after the call to VERT_T3D. Using the NO_COPY requires less memory.

### NO_DIVIDE

Normally, when a [*x*, *y*, *z*, 1] vector is transformed by a 4x4 matrix, the final homogeneous coordinates are obtained by dividing the *x*, *y*, and *z* components of the result vector by the fourth element in the result vector. Setting the NO_DIVIDE keyword will prevent VERT_T3D from performing this division. In some cases (usually when a perspective transformation is involved) the fourth element in the result vector can be very close to (or equal to) zero.

### SAVE_DIVIDE

Set this keyword to a named variable that will hold receive the fourth element of the transformed vector(s). If *Vertex_list* is a vector then SAVE_DIVIDE is a scalar. If *Vertex_list* is an array then SAVE_DIVIDE is an array of *n* elements. This keyword only has effect when the NO_DIVIDE keyword is set.

## Examples

Transform four points representing a square in the x-y plane by first translating +2.0 in the positive X direction, and then rotating 60.0 degrees about the Y axis.

```
points = [[0.0, 0.0, 0.0], [1.0, 0.0, 0.0], $
          [1.0, 1.0, 0.0], [0.0, 1.0, 0.0]]
T3D, /RESET
T3D, TRANSLATE=[2.0, 0.0, 0.0]
T3D, ROTATE=[0.0, 60.0, 0.0]
points = VERT_T3D(points)
```

## Version History

Introduced: Pre 4.0

T3D

# VOIGT

The VOIGT function returns the value of the classical Voigt function, H(*a*, *u*), defined in terms of the Voigt damping parameter *a* and the frequency offset *u*:

$$H(a, u) = \frac{a}{\pi} \int_{-\infty}^{\infty} \frac{e^{-y^2} dy}{a^2 + (u - y)^2}$$

The dimensionless frequency offset *u* and the damping parameter *a* are determined by:

$$u = \frac{\nu - \nu_0}{\Delta\nu_D}$$

$$a = \frac{\Gamma}{4\pi\Delta\nu_D}$$

where $\nu_0$ is the line center frequency and the Doppler width $\Delta\nu_D$ (assuming no turbulence), is defined as:

$$\Delta\nu_D = \frac{\nu_0}{c} b = \frac{\nu_0}{c} \sqrt{2kT/m}$$

and, $\Gamma$ is the transition rate:

$$\Gamma = \gamma + 2\nu_{col}$$

where $\gamma$ is the spontaneous decay rate, and $\nu_{col}$ is the atomic collision rate. (See *Radiative Processes in Astrophysics* by G. B. Rybicki and A. P. Lightman (1979) p. 291 for more information.)

The Voigt function can be used to compute the intensity of an atomic absorption line profile (also known as a VOIGT profile). The line profile $\phi(a, u)$ is defined as:

$$\phi(a, u) \equiv \frac{H(a, u)}{\Delta v_D \sqrt{\pi}}$$

The algorithm is from Armstrong, *JQSRT 7*, 85. (1967). The definition of the classical Voigt function H(*a*,*u*) can be found in Equation 7.4.13 of Abramowitz, M. and Stegun, I.A., 1964, *Handbook of Mathematical Functions* (Washington:National Bureau of Standards).

# Syntax

*Result* = VOIGT(*A*, *U*)

# Return Value

If both arguments are scalars, the function returns a scalar. If both arguments are arrays, the function matches up the corresponding elements of A and U, returning an array with the same dimensions as the smallest array. If one argument is a scalar and the other argument is an array, the function uses the scalar value with each element of the array, and returns an array with the same dimensions as the smallest input array. If A is double-precision, the result is double-precision, otherwise the result is single-precision.

# Arguments

## A

A scalar or array specifying the values for the Voigt damping parameter.

## U

A scalar or array specifying the values for the dimensionless frequency offset in Doppler widths.

# Keywords

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

# Version History

Introduced: Pre 4.0

# See Also

LEEFILT, ROBERTS, SOBEL

# VORONOI

The VORONOI procedure computes the Voronoi polygon of a point within an irregular grid of points, given the Delaunay triangulation. The Voronoi polygon of a point contains the region closer to that point than to any other point.

For interior points, the polygon is constructed by connecting the midpoints of the lines connecting the point with its Delaunay neighbors. Polygons are traversed in a counterclockwise direction.

For exterior points, the set is described by the midpoints of the connecting lines, plus the circumcenters of the two triangles that connect the point to the two adjacent exterior points.

This routine is written in the IDL language. Its source code can be found in the file `voronoi.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

VORONOI, *X*, *Y*, *I0*, *C*, *Xp*, *Yp*, *Rect*

## Arguments

### X

An array containing the X locations of the points.

### Y

An array containing the Y locations of the points.

### I0

An array containing the indices of the points.

### C

A connectivity list from the Delaunay triangulation. This list is produced with the CONNECTIVITY keyword of the TRIANGULATE procedure.

### Xp, Yp

Named variables that will contain the X and Y vertices of Voronoi polygon.

### Rect

The bounding rectangle: [Xmin, Ymin, Xmax, Ymax]. Because the Voronoi polygon (VP) for points on the convex hull extends to infinity, a clipping rectangle must be supplied to close the polygon. This rectangle has no effect on the VP of interior points. If this rectangle does not enclose all the Voronoi vertices, the results will be incorrect. If this parameter, which must be a named variable, is undefined or set to a scalar value, it will be calculated.

## Examples

To draw the Voronoi polygons of each point of an irregular grid:

```
N = 20

; Create a random grid of N points:
X = RANDOMU(seed, N)
Y = RANDOMU(seed, N)

; Triangulate it:
TRIANGULATE, X, Y, tr, CONN=C

FOR I=0, N-1 DO BEGIN & $
   ; Get the ith polygon:
   VORONOI, X, Y, I, C, Xp, Yp & $
      ; Draw it:
      POLYFILL, Xp, Yp, COLOR = (I MOD 10) + 2 & $
ENDFOR
```

## Version History

Introduced: Pre 4.0

TRIANGULATE

# VOXEL_PROJ

The VOXEL_PROJ function generates visualizations of volumetric data by computing 2-D projections of a colored, semi-transparent volume. Parallel rays from any given direction are cast through the volume, onto the viewing plane. User-selected colors and opacities can be assigned to arbitrary data ranges, simulating the appearance of the materials contained within the volume.

The VOXEL_PROJ function can be combined with the Z-buffer to render volume data over objects. Cutting planes can also be specified to view selected portions of the volume. Other options include: selectable resolution to allow quick “preview” renderings, and average and maximum projections.

VOXEL_PROJ renders volumes using an algorithm similar to the one described by Drebin, Carpenter, and Hanrahan, in “Volume Rendering”, *Computer Graphics*, Volume 22, Number 4, August 1988, pp. 125-134, but without the surface extraction and enhancement step.

Voxel rendering can be quite time consuming. The time required to render a volume is proportional to the viewing areas size, in pixels, times the thickness of the volume cube in the viewing direction, divided by the product of the user-specified X, Y, and Z steps.

## Syntax

*Result* = VOXEL_PROJ( *V* [, *RGBO*] [, BACKGROUND=*array*] [, CUTTING_PLANE=*array*] [, /INTERPOLATE] [, /MAXIMUM_INTENSITY] [, STEP=*[Sx, Sy, Sz]*] [, XSIZE=*pixels*] [, YSIZE=*pixels*] [, ZBUFFER=*int_array*] [, ZPIXELS=*byte_array*] )

## Return Value

Returns the specified voxel projection results.

## Arguments

### V

A three-dimensional array containing the volume to be rendered. This array is converted to byte type if necessary.

### RGBO

This optional parameter is used to specify the look-up tables that indicate the color and opacity of each voxel value. This argument can be one of the following types:

- A (256, 4) byte array for TrueColor rendering. This array represents 256 sets of red, green, blue, and opacity (RGBO) components for each voxel value, scaled into the range of bytes (0 to 255). The R, G, and B components should already be scaled by the opacity. For example, if a voxel value of 100 contains a material that is red, and 35% opaque, the RGBO values should be, respectively: [89, 0, 0, 89] because 255 * 0.35 = 89. If more than one material is present, the RGBO arrays contain the sum of the individual RGBO arrays. The content and shape of the RGBO curves is highly dependent upon the volume data and experimentation is often required to obtain the best display.
- A (256, 2) byte array for volumes with only one material or monochrome rendering. This array represents 256 sets of pixel values and their corresponding opacities for each voxel value.
- If this argument is omitted, the average projection method, or maximum intensity method (if the MAXIMUM_INTENSITY keyword is set) is used.

## Keywords

### BACKGROUND

A one- or three-element array containing the background color indices. The default is (0,0,0), yielding a black background with most color tables.

### CUTTING_PLANE

A floating-point array specifying the coefficients of additional cutting planes. The array has dimensions of (4, N), where N is the number of additional cutting planes from 1 to 6. Cutting planes are constraints in the form of:

C[0] * X + C[1] * Y + C[2] * Z + D > 0

The X, Y, and Z coordinates are specified in voxel coordinates. For example, to specify a cutting plane that excludes all voxels with an X value greater than 10:

CUTTING_PLANE = [-1.0, 0, 0, 10.], for the constraint: -X + 10 > 0.

### INTERPOLATE

Set this keyword to use tri-linear interpolation to determine the data value for each step on a ray. Otherwise, the nearest-neighbor method is used. Setting this keyword

improves the quality of images produced, especially when the volume has low resolution in relation to the size of the viewing plane, at the cost of more computing time.

## MAXIMUM_INTENSITY

Set this keyword to make the value of each pixel in the viewing plane the maximum data value along the corresponding ray. The *RGBO* argument is ignored if present.

## STEP

Set this keyword to a three-element vector, [*Sx*, *Sy*, *Sz*], that controls the resolution of the resulting projection. The first two elements contain the step size in the X and Y view plane, in pixels. The third element is the sampling step size in the Z direction, given in voxels. *Sx* and *Sy* must be integers equal to or greater than one, while *Sz* can contain a fractional part. If *Sx* or *Sy* are greater than one, the values of intermediate pixels in the output image are linearly interpolated. Higher step sizes require less time because fewer rays are cast, at the expense of lower resolution in the output image.

## XSIZE

The width, in pixels, of the output image. If this keyword is omitted, the output image is as wide as the currently-selected output device.

## YSIZE

The height, in pixels, of the output image. If this keyword is omitted, the output image is as tall as the currently selected output device.

## ZBUFFER

An integer array, with the same width and height as the output image, that contains the depth portion of the Z-buffer. Include this parameter to combine the previously-read contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

## ZPIXELS

A byte array, with the same width and height as the output image, that contains the image portion of the Z-buffer. Include this parameter to combine the contents of a Z-buffer with a voxel rendering. See the third example, below, for details.

# Examples

## Example 1

In the following example, assume that variable V contains a volume of data, with dimensions Vx by Vy by Vz. The volume contains two materials, muscle tissue represented by a voxel range of 50 to 70, that we want to render with red color, and an opacity of 20; and bone tissue represented by a voxel range of 220-255, that we want to render with white color, and an opacity of 50:

```
; Create the opacity vector:
rgbo = BYTARR(256,4)

; Red and opacity for muscle:
rgbo[50:70, [0,3]] = 20

; White and opacity for bone:
rgbo[220:255, *] = 50
```

## Example 2

Although it is common to use trapezoidal or Gaussian functions when forming the RGBO arrays, this example uses rectangular functions for simplicity.

```
; Set up the axis scaling and default rotation:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute projected image:
C = VOXEL_PROJ(V, rgbo)

; Convert from 24-bit to 8-bit image and display:
TV, COLOR_QUAN(C, 3, R, G, B)

; Load quantized color tables:
TVLCT, R, G, B
```

This example required approximately 27 seconds on a typical workstation to compute the view in a 640- by 512-pixel viewing window. Adding the keyword STEP=[2,2,1] in the call to VOXEL_PROJ decreased the computing time to about 8 seconds, at the expense of slightly poorer resolution.

When viewing a volume with only one constituent, the RGBO array should contain only an intensity/opacity value pair. To illustrate, if in the above example, only muscle was of interest we create the RGBO argument as follows:

```
; Create an empty 256 x 2 array:
rgbo = BYTARR(256,2)
```

```
; Intensity and opacity for muscle:
rgbo[50:70, *] = 20
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Compute and display the projected image:
TV, VOXEL_PROJ(V, rgbo)

; Create color table array for red:
C = (FINDGEN(256)/255.) # [255., 0., 0]

; Load colors:
TVLCT, C[*,0], C[*,1], C[*,2]
```

## Example 3

This example demonstrates combining a volume with the contents of the Z-buffer:

```
; Set plotting to Z-buffer:
SET_PLOT, 'Z'

; Turn on Z buffering:
DEVICE, /Z_BUFFER

; Set scaling:
SCALE3, XRANGE=[0, Vx-1], YRANGE=[0, Vy-1], ZRANGE=[0, Vz-1]

; Draw a polygon at z equal to half the depth:
POLYFILL, [0, Vx-1, Vx-1, 0], [0, 0, Vy-1, Vy-1], Vz/2., /T3D

; Read pixel values from the Z-buffer:
zpix = TVRD()

; Read depth values from the Z-buffer:
zbuff = TVRD(/WORDS,/CHAN)

; Back to display window:
SET_PLOT, 'X'

; Compute the voxel projection and use the ZPIXELS and ZBUFFER
; keywords to combine the volume with the previously-read contents
; of the Z-buffer:
C = VOXEL_PROJ(V, rgbo, ZPIX=zpix, ZBUFF=zbuff)

;Convert from 24-bit to 8-bit image and display.
TV, COLOR_QUAN(C, 3, R, G, B)

; Load the quantized color tables:
TVLCT, R, G, B
```

# WAIT

The WAIT procedure suspends execution of an IDL program for a specified period. Note that because of other activity on the system, the duration of program suspension may be longer than requested.

## Syntax

WAIT, *Seconds*

## Arguments

### Seconds

The duration of the wait, specified in seconds. This parameter can be a floating-point value to specify a fractional number of seconds.

## Keywords

None.

## Examples

To make an IDL program suspend execution for about five and one half seconds, use the command:

```
WAIT, 5.5
```

## Version History

Introduced: Original

EXIT, STOP

# WARP_TRI

The WARP_TRI function returns an image array with a specified geometric correction applied. Images are warped using control (tie) points such that locations (*Xi*, *Yi*) are shifted to (*Xo*, *Yo*).

The irregular grid defined by (*Xo*, *Yo*) is triangulated using TRIANGULATE. Then the surfaces defined by (*Xo*, *Yo*, *Xi*) and (*Xo*, *Yo*, *Yi*) are interpolated using TRIGRID to get the locations in the input image of each pixel in the output image. Finally, INTERPOLATE is called to obtain the result. Linear interpolation is used by default. Smooth quintic interpolation is used if the QUINTIC keyword is set.

This routine is written in the IDL language. Its source code can be found in the file `warp_tri.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = WARP_TRI( *Xo*, *Yo*, *Xi*, *Yi*, *Image* [, OUTPUT_SIZE=*vector*] [, /QUINTIC] [, /EXTRAPOLATE] [, /TPS] )

## Return Value

Returns the warped image array.

## Arguments

### Xo, Yo

Vectors containing the locations of the control (tie) points in the output image.

### Xi, Yi

Vectors containing the location of the control (tie) points in the input image. *Xi* and *Yi* must be the same length as *Xo* and *Yo*.

### Image

The image to be warped. May be any type of data.

# Keywords

## OUTPUT_SIZE

Set this keyword equal to a 2-element vector containing the size of the output image. If omitted, the output image is the same size as *Image*.

## QUINTIC

Set this keyword to use smooth quintic interpolation. Quintic interpolation is slower but the derivatives are continuous across triangles, giving a more pleasing result than the default linear interpolation.

## EXTRAPOLATE

Set this keyword to extrapolate outside the convex hull of the tie points. Setting this keyword implies the use of QUINTIC interpolation.

## TPS

Set this keyword to use Thin Plate Spline interpolation, which interpolates a set of irregularly sampled data value over a regular two dimensional grid. Thin plate splines are ideal for modeling functions with complex local distortions, such as warping functions, which are too complex to be fit with polynomials.

# Version History

Introduced: Pre 4.0

# See Also

INTERPOLATE, TRIANGULATE, TRIGRID

# WATERSHED

The WATERSHED function applies the morphological watershed operator to a grayscale image. This operator segments images into watershed regions and their boundaries. Considering the gray scale image as a surface, each local minimum can be thought of as the point to which water falling on the surrounding region drains. The boundaries of the watersheds lie on the tops of the ridges. This operator labels each watershed region with a unique index, and sets the boundaries to zero.

Typically, morphological gradients, or images containing extracted edges are used for input to the watershed operator. Noise and small unimportant fluctuations in the original image can produce spurious minima in the gradients, which leads to oversegmentation. Smoothing, or manually marking the seed points are two approaches to overcoming this problem. For further reading, see Dougherty, “An Introduction to Morphological Image Processing”, SPIE Optical Engineering Press, 1992.

## Syntax

*Result* = WATERSHED ( *Image* [, CONNECTIVITY={4 | 8} ] )

## Return Value

Returns an image of the same dimensions as the input image. Each pixel of the result will be either zero if the pixel falls along the segmentation between basins, or the identifier of the basin in which that pixel falls.

## Arguments

### Image

The two-dimensional image to be segmented. *Image* is converted to byte type if necessary.

## Keywords

### CONNECTIVITY

Set this keyword to either 4 (to select 4-neighbor connectivity) or 8 (to select 8-neighbor connectivity). Connectivity indicates which pixels in the neighborhood of a given pixel are sampled during the segmentation process. 4-neighbor connectivity

samples only the pixels that are immediately adjacent horizontally and vertically. 8-neighbor connectivity samples the diagonally adjacent neighbors in addition to the immediate horizontal and vertical neighbors. The default is 4-neighbor connectivity.

## Examples

The following code crudely segments the grains in the data file in the IDL Demo data directory containing an magnified image of grains of pollen. Note that the IDL Demos must be installed in order to read the image used in this example.

It inverts the image, because the watershed operator finds holes, and the grains of pollen are bright. Next, the morphological closing operator is applied with a disc of radius 9, contained within a 19 by 19 kernel, to eliminate holes in the image smaller than the disc. The watershed operator is then applied to segment this image. The borders of the watershed images, which have pixel values of zero, are then merged with the original image and displayed as white.

```
;Radius of disc...
r = 9

;Create a disc of radius r
disc = SHIFT(DIST(2*r+1), r, r) LE r

;Read the image
READ_JPEG, FILEPATH('pollens.jpg', $
   SUBDIR=['examples','demo','demodata']), a

;Invert the image
b = MAX(a) - a

TVSCL, b, 0

;Remove holes of radii less than r
c = MORPH_CLOSE(b, disc, /GRAY)

TVSCL, c, 1

;Create watershed image
d = WATERSHED(c)

;Display it, showing the watershed regions
TVSCL, d, 2

;Merge original image with boundaries of watershed regions
e = a > (MAX(a) * (d EQ 0b))

TVSCL, e, 3
```

# Wavelet Toolkit

For information, see the *Chapter 1, "Introduction to the IDL Wavelet Toolkit"* in the *IDL Wavelet Toolkit* manual.

# WDELETE

The WDELETE procedure deletes IDL windows.

## Syntax

WDELETE [, *Window_Index* [, ...]]

## Arguments

### Window_Index

A list of one or more window indices to delete. If this argument is not specified, the current window (as specified by the system variable !D.WINDOW) is deleted. If the window being deleted is not the active window, the value of !D.WINDOW remains unchanged. If the window being deleted is the active window, !D.WINDOW is set to the highest numbered window index or to -1 if no windows remain open.

If this window index is the widget ID of a draw widget, that widget is deleted.

## Keywords

None.

## Examples

Create IDL graphics window number 5 by entering:

```
WINDOW, 5
```

Delete window 5 by entering:

```
WDELETE, 5
```

## Version History

Introduced: Original

# WF_DRAW

The WF_DRAW procedure draws weather fronts of various types using parametric spline interpolation to smooth the lines. WF_DRAW uses the POLYFILL routine to make the annotations on the front lines.

This routine is written in the IDL language. Its source code can be found in the file `wf_draw.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

WF_DRAW, *X*, *Y* [[, /COLD | , FRONT_TYPE=1] | [, /WARM | , FRONT_TYPE=2] | [, /OCCLUDED | , FRONT_TYPE=3] | [, /STATIONARY | , FRONT_TYPE=4] | [, /CONVERGENCE | , FRONT_TYPE=5]] [, COLOR=*value*] [, /DATA | , /DEVICE | , /NORMAL] [, INTERVAL=*value*] [, PSYM=*value*] [, SYM_HT=*value*] [, SYM_LEN=*value*] [, THICK=*value*]

## Arguments

### X, Y

Vectors of abscissae and ordinates defining the front to be drawn.

## Keywords

### COLD

Set this keyword to draw a cold front. The default is a plain line with no annotations. A cold front can also be specified by setting the keyword FRONT_TYPE = 1.

### COLOR

Use this keyword to specify the color to use. The default = !P.COLOR.

### CONVERGENCE

Set this keyword to draw a convergence line. A convergence line can also be specified by setting the keyword FRONT_TYPE = 5.

### DATA

Set this keyword if X and Y are specified in data coordinates.

## DEVICE

Set this keyword if X and Y are specified in device coordinates.

## FRONT_TYPE

Set this keyword equal to the numeric index of type of front to draw. Front type indices are as follows: COLD=1, WARM=2, OCCLUDED=3, STATIONARY=4, CONVERGENCE = 5. Not required if plain line is desired or if an explicit front type keyword is specified.

## INTERVAL

Use this keyword to specify the spline interpolation interval, in normalized units. The default = 0.01. Larger values give coarser approximations to curves, smaller values make more interpolated points.

## NORMAL

Set this keyword if X and Y are specified in normalized coordinates. This is the default.

## OCCLUDED

Set this keyword to draw an occluded front. An occluded front can also be specified by setting the keyword FRONT_TYPE = 3.

## PSYM

Set this keyword a standard PSYM value to draw a marker on each actual (*X*, *Y*) data point. See “PSYM” on page 3878 for a list of the symbol types.

## STATIONARY

Set this keyword to draw a stationary front. A stationary front can also be specified by setting the keyword FRONT_TYPE = 4.

## SYM_HT

Use this keyword to specify the height of front symbols, in normalized units. The default = 0.02.

## SYM_LEN

Use this keyword to specify the length and spacing factor for front symbols, in normalized units. The default = 0.15.

### THICK

Use this keyword to specify the line thickness. The default = 1.0.

### WARM

Set this keyword to draw a warm front. A warm front can also be specified by setting the keyword FRONT_TYPE = 2.

## Examples

This example draws various fronts on a map of the United States. Note that this example code is in the file `wf_draw.pro`, and can be run by entering `test_wf_draw` at the IDL command line.

```
PRO test_wf_draw

 MAP_SET, LIMIT = [25, -125, 50, -70], /GRID, /USA
 WF_DRAW, [ -120, -110, -100], [30, 50, 45], /COLD, /DATA, THICK=2
 WF_DRAW, [ -80, -80, -75], [ 50, 40, 35], /WARM, /DATA, THICK=2

ANNOTATE, XYOUTS

# WHERE

The WHERE function returns a vector that contains the one-dimensional subscripts of the nonzero elements of *Array_Expression*. The length of the resulting vector is equal to the number of nonzero elements in *Array_Expression*. Frequently the result of WHERE is used as a vector subscript to select elements of an array using given criteria.

### Note: When WHERE Returns –1

If all the elements of *Array_Expression* are zero, WHERE returns a scalar integer with a value of –1. Attempting to use this result as an index into another array results in a “subscripts out of bounds” error. In situations where this is possible, code similar to the following can be used to avoid errors:

```
; Use Count to get the number of nonzero elements:
index = WHERE(array, count)

; Only subscript the array if it’s safe:
IF count NE 0 THEN result = array[index]
```

## Syntax

*Result* = WHERE( *Array_Expression* [, *Count*] [, COMPLEMENT=*variable*] [, /L64] [, NCOMPLEMENT=*variable*] )

## Return Value

Returns a longword vector containing the subscripts of non-zero array elements matching the specified conditions.

## Arguments

### Array_Expression

The array to be searched. Both the real and imaginary parts of a complex number must be zero for the number to be considered zero.

### Count

A named variable that will receive the number of nonzero elements found in *Array_Expression*. This value is returned as a longword integer.

**Note**

The system variable !ERR is set to the number of nonzero elements. This effect is for compatibility with previous versions of IDL and should *not* be used in new code. Use the COUNT argument to return this value instead.

# Keywords

## COMPLEMENT

Set this keyword to a named variable that receives the subscripts of the zero elements of *Array_Expression*. These are the subscripts that are not returned in *Result*. Together, *Result* and COMPLEMENT specify every subscript in *Array_Expression*. If there are no zero elements in *Array_Expression*, COMPLEMENT returns a scalar integer with the value -1.

## L64

By default, the result of WHERE is 32-bit integer when possible, and 64-bit integer if the number of elements being processed requires it. Set L64 to force 64-bit integers to be returned in all cases.

**Note**

Only 64-bit versions of IDL are capable of creating variables requiring a 64-bit result. Check the value of !VERSION.MEMORY_BITS to see if your IDL is 64-bit or not.

## NCOMPLEMENT

Set this keyword to a named variable that receives the number of zero elements found in *Array_Expression*. This value is the number of subscripts that will be returned via the COMPLEMENT keyword if it is specified.

## Thread Pool Keywords

This routine is written to make use of IDL's *thread pool*, which can increase execution speed on systems with multiple CPUs. The values stored in the !CPU system variable control whether IDL uses the thread pool for a given computation. In addition, you can use the thread pool keywords TPOOL_MAX_ELTS, TPOOL_MIN_ELTS, and TPOOL_NOTHREAD to override the defaults established by !CPU for a single invocation of this routine. See Appendix C, "Thread Pool Keywords" for details.

# Examples

## Example 1

```
; Create a 10-element integer array where each element is
; set to the value of its subscript:
array = INDGEN(10)
PRINT, 'array = ', array

; Find the subscripts of all the elements in the array that have
; a value greater than 5:
B = WHERE(array GT 5, count, COMPLEMENT=B_C, NCOMPLEMENT=count_c)

; Print how many and which elements met the search criteria:
PRINT, 'Number of elements > 5: ', count
PRINT, 'Subscripts of elements > 5: ', B
PRINT, 'Number of elements <= 5: ', count_c
PRINT, 'Subscripts of elements <= 5: ', B_C
```

IDL prints:

```
array =  0  1  2  3  4  5  6  7  8  9
Number of elements > 5:  4
Subscripts of elements > 5:  6  7  8  9
Number of elements <= 5:  6
Subscripts of elements <= 5:  0  1  2  3  4  5
```

## Example 2

The WHERE function behaves differently with different kinds of array expressions. For instance, if a relational operator is used to compare an array, A, with a scalar, B, then every element of A is searched for B. However, if a relational operator is used to compare two arrays, C and D, then a comparison is made between each corresponding element (i.e. $C_i$ & $D_i$, $C_i$+1 & $D_i$+1, etc) of the two arrays. If the two arrays have different lengths then a comparison is only made up to the number of elements for the shorter array. The following example illustrates this behavior:

```
; Compare array, a, and scalar, b:
a = [1,2,3,4,5,5,4,3,2,1]
b = 5
PRINT, 'a = ', a
PRINT, 'b = ', b

result=WHERE(a EQ b)
PRINT,'Subscripts of a that equal b: ', result

; Now compare two arrays of different lengths:
c = [1,2,3,4,5,5,4,3,2,1]
```

```
d = [0,2,4]
PRINT, 'c = ', c
PRINT, 'd = ', d

result=WHERE(c EQ d)
PRINT, 'Subscripts of c that equal d: ', result
```

IDL prints:

```
a =  1  2  3  4  5  5  4  3  2  1
b =  5
Subscripts of a that equal b:  4  5

c =  1  2  3  4  5  5  4  3  2  1
d =  0  2  4
Subscripts of c that equal d: 1
```

Note that WHERE found only one element in the array d that equals an element in array c. This is because only the first three elements of c were searched, since d has only three elements.

ARRAY_INDICES, UNIQ

# WHILE...DO

The WHILE...DO statement performs its subject statement(s) as long as the expression evaluates to true. The subject is never executed if the condition is initially false.

**Note**

For information on using WHILE...DO and other IDL program control statements, see Chapter 12, “Program Control” in the *Building IDL Applications* manual.

## Syntax

WHILE *expression* DO *statement*

or

WHILE *expression* DO BEGIN

*statements*

ENDWHILE

## Examples

```
i = 0
WHILE (i EQ 1) DO PRINT, i
```

Because the expression (which is false in this case) is evaluated before the subject statement is executed, this code yields no output.

## Version History

Introduced: Original

# WIDGET_ACTIVEX

The WIDGET_ACTIVEX function is used to incorporate an ActiveX control into an IDL widget hierarchy. IDL provides the same object method and property manipulation facilities for ActiveX controls as it does for COM objects incorporated using the IDLcomIDispatch object interface, but adds the ability to process events generated by the ActiveX control using IDL's widget event handling mechanisms.

**Note**

IDL can only incorporate ActiveX controls on Windows NT/2000/XP (and later) platforms.

When you use the WIDGET_ACTIVEX routine, IDL automatically creates an IDLcomActiveX object that encapsulates the ActiveX control. You can then call the ActiveX control's methods using IDL object syntax, as discussed in Chapter 5, "Using ActiveX Controls in IDL" in the *External Development Guide* manual. You should be familiar with the material in that chapter before attempting to incorporate ActiveX controls in your IDL programs.

**Note**

If the COM object you want to use in your IDL application is *not* an ActiveX control, use the IDLcomIDispatch object class.

## Syntax

*Result* = WIDGET_ACTIVEX( *Parent*, *COM_ID*, [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FUNC_GET_VALUE=*string*] [ID_TYPE=*value*] [, KILL_NOTIFY=*string*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*] )

## Return Value

The returned value is the widget ID of the ActiveX widget. Note that the *widget value* of the ActiveX widget is an object reference to the IDLcomActiveX object that encapsulates the specified ActiveX control.

# Arguments

## Parent

The widget ID of the parent widget of the new ActiveX control.

## COM_ID

A string value specifying the class or program ID of the COM object to create. Note that if you specify a COM program ID via this argument, you must also set the ID_TYPE keyword.

**Note**

The class or program ID must follow the standard Microsoft naming convention. See Chapter 5, "Using ActiveX Controls in IDL" in the *External Development Guide* manual for more on class and program IDs, and their use with WIDGET_ACTIVEX.

# Keywords

## ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

## ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

## ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## ID_TYPE

The type of COM object ID specified by the *COM_ID* parameter (class or program). If set to 0 (zero), the value is a class ID (the default). If set to 1 (one), the value is a program ID.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_BASE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string ( ' '). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

## Keywords to WIDGET_CONTROL

The GET_VALUE keyword to the WIDGET_CONTROL procedure is used to retrieve an object reference to the IDLcomActiveX object that underlies the ActiveX widget. The object reference returned in this manner can be used to call the ActiveX control's native methods.

## Examples

For examples using WIDGET_ACTIVEX, see Chapter 5, “Using ActiveX Controls in IDL” in the *External Development Guide* manual.

## Version History

Introduced: 5.5

# WIDGET_BASE

The WIDGET_BASE function is used to create base widgets. Base widgets serve as containers for other widgets.

**Note**

In most cases, you will want let IDL determine the placement of widgets within the base widget. Do this by specifying either the COLUMN keyword or the ROW keyword. See "Positioning Child Widgets Within a Base" in the following section for details.

## Exclusive And Non-Exclusive Bases

If the EXCLUSIVE or NONEXCLUSIVE keywords are specified, the base only allows button widget children.

## Positioning Child Widgets Within a Base

The standard base widget does not impose any placement constraints on its child widgets. Children of a "bulletin board" base (a base that was created without setting the COLUMN or ROW keywords) have an offset of (0,0) unless an offset is explicitly specified via the XOFFSET or YOFFSET keywords. This means that if you do not specify any of COLUMN, ROW, XOFFSET, or YOFFSET keywords, child widgets will be placed one on top of the other in the upper left corner of the base.

However, laying out widgets using the XSIZE, YSIZE, XOFFSET, and YOFFSET keywords can be both tedious and error-prone. Also, if you want your widget application to display properly on different platforms, you should use the COLUMN and ROW keywords to influence child widget layouts instead of explicitly formatting your interfaces.

When the ROW or COLUMN keywords are specified, the base decides how to lay out its children, and any XOFFSET and YOFFSET keywords specified for such children are ignored.

## Positioning Top-Level Bases

When locating a new top level window, some window managers ignore the program's positioning requests and either choose a position or allow the user to choose. In such cases, the XOFFSET and YOFFSET keywords to WIDGET_BASE will not have an effect. The window manager may provide a way to disable this positioning style. The Motif window manager (mwm) can be told to honor positioning requests by placing the following lines in your `.Xdefaults` file:

```
Mwm*clientAutoPlace: False
Mwm*interactivePlacement: False
```

## Iconizing, Layering, and Destroying Groups of Top-Level Bases

Group membership (defined via the GROUP_LEADER keyword) controls the way top-level base widgets are iconized, layered, and destroyed.

**Note**

A group can contain sub-groups. Group behavior affects all members of a group and its sub-groups. For example, suppose we create three top-level base widgets with the following group hierarchy:

```
base1 = WIDGET_BASE()
base2 = WIDGET_BASE(GROUP_LEADER=base1)
base3 = WIDGET_BASE(GROUP_LEADER=base2)
```

Effectively, two groups are created. One group has `base2` as its leader and `base3` as its member. The other group has `base1` as its leader and both `base2` and `base3` as members. If `base1` is iconized, both `base2` and `base3` are iconized as well. If `base2` is iconized, `base3` is iconized but `base1` is not.

Widgets behave slightly differently when displayed on different platforms, and depending on whether they are floating or modal bases. The following rules apply to groups of widgets within a group leader/member hierarchy. Widgets that do not belong to the same group hierarchy cannot influence each other.

### Iconization and Mapping

Bases and groups of bases can be *iconized* (or *minimized*) by clicking the system minimize control. Bases and groups of bases can also be *mapped* (made visible) and *unmapped* (made invisible).

**Motif —** Mapping or unmapping a group leader has no effect on the mapped state of the group members. Iconifying or mapping a group member has no effect on the group leader. Modal bases cannot be unmapped.

Bases and groups of bases can be iconized (or minimized) by clicking the system minimize control. When a group leader is iconized, all members of the group are iconized as well. Similarly, when a group leader is restored, all members of the group are restored.

**Windows —** Mapping or unmapping a group leader has no effect on the mapped state of the group members. Iconifying or mapping a group member has no effect on the group leader. Modal bases cannot be unmapped.

Bases and groups of bases can be iconized (or minimized) by clicking the system minimize control. When a group leader is iconized, all members of the group are iconized as well. Similarly, when a group leader is restored, all members of the group are restored.

### Layering

*Layering* is the process by which groups of widgets seem to share the same plane on the display screen. Within a layer on the screen, widgets have a *Z-order*, or front-to-back order, that defines which widgets appear to be on top of other widgets.

**Motif —** All elements on the screen—widgets, the IDLDE, other Motif applications—share a single layer and have an arbitrary Z-order. There is no special layering of IDL widgets.

**Windows —** All non-floating and non-modal widgets within a group hierarchy share the same layer—that is, when one group member has the input focus, all members of the group hierarchy are displayed in a layer that appears in front of all other groups or applications. Within the layer, the widgets can have an arbitrary Z-order.

Widgets that are floating or modal always float above their group leaders.

### Destruction

When a group leader widget is destroyed, either programmatically or by clicking on the system “close” button, all members of the group and all sub-groups are destroyed as well.

If a modal base is on the display, it must be dismissed before any widget can be destroyed.

## Syntax

*Result* = WIDGET_BASE( [*Parent*] [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, /MBAR | , /MODAL] [, /BASE_ALIGN_BOTTOM | , /BASE_ALIGN_CENTER | , /BASE_ALIGN_LEFT | , /BASE_ALIGN_RIGHT | , /BASE_ALIGN_TOP] [, /COLUMN | , /ROW] [, /CONTEXT_EVENTS] [, /CONTEXT_MENU] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, /EXCLUSIVE | , /NONEXCLUSIVE] [, /FLOATING] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, /GRID_LAYOUT] [, GROUP_LEADER=*widget_id*{must specify for modal dialogs}] [, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=*string*] [, /MAP{not for modal bases}] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SCROLL{not for modal bases}]

[, /SENSITIVE] [, SPACE=*value*{ignored if exclusive or nonexclusive}]
[, TITLE=*string*] [, TLB_FRAME_ATTR=*value*{top-level bases only}]
[, /TLB_ICONIFY_EVENTS{top-level bases only}]
[, /TLB_KILL_REQUEST_EVENTS{top-level bases only}]
[, /TLB_MOVE_EVENTS{top-level bases only}] [, /TLB_SIZE_EVENTS{top-level bases only}] [, /TOOLBAR] [, /TRACKING_EVENTS] [, UNAME=*string*]
[, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, XOFFSET=*value*]
[, XPAD=*value*{ignored if exclusive or nonexclusive}] [, XSIZE=*value*]
[, X_SCROLL_SIZE=*value*] [, YOFFSET=*value*] [, YPAD=*value*{ignored if exclusive or nonexclusive}] [, YSIZE=*value*] [, Y_SCROLL_SIZE=*value*] )

**X Windows Keywords:** [, DISPLAY_NAME=*string*]
[, RESOURCE_NAME=*string*] [, RNAME_MBAR=*string*]

# Return Value

The returned value of this function is the widget ID of the newly-created base.

# Arguments

## Parent

The widget ID of the parent widget. To create a *top-level* base, omit the *Parent* argument.

# Keywords

## ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

## ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

## ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

**Warning**

You cannot specify both an APP_MBAR and an MBAR for the same top-level base widget. Doing so will cause an error.

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the KBRD_FOCUS_EVENTS keyword to keep track of which widget has (or last had) the keyboard focus.

## BASE_ALIGN_BOTTOM

Set this keyword to make all children of the new base align themselves with the bottom of the base by default. To take effect, you must also set the ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

## BASE_ALIGN_CENTER

Set this keyword to make all children of the new base align themselves with the center of the base by default. To take effect, you must also set the COLUMN or ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created. In ROW bases, child widgets will be vertically centered. In COLUMN bases, child widgets will be horizontally centered.

## BASE_ALIGN_LEFT

Set this keyword to make all children of the new base align themselves with the left side of the base by default. To take effect, you must also set the COLUMN keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

## BASE_ALIGN_RIGHT

Set this keyword to make all children of the new base align themselves with the right side of the base by default. To take effect, you must also set the COLUMN keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

## BASE_ALIGN_TOP

Set this keyword to make all children of the new base align themselves with the top of the base by default. To take effect, you must also set the ROW keyword for the new base. The default can be overridden for individual child widgets by setting a different ALIGN_XXX keyword when the child widget is created.

## COLUMN

If this keyword is included, the base lays out its children in columns. The value of this keyword specifies the number of columns to be used. The number of child widgets in each column is calculated by dividing the number of child widgets created by the number of columns specified. When one column is filled, a new one is started.

Specifying both the COLUMN and ROW keywords causes an error.

### Column Width

The width of each column is determined by the width of the widest widget in that column. If the GRID_LAYOUT keyword is set, all columns are as wide as the widest widget in the base.

### Horizontal Size of Widgets

If any of the BASE_ALIGN_* keywords to WIDGET_BASE is set, each widget has its “natural” width, determined either by the value of the widget or by the XSIZE keyword. Similarly, if any of the child widgets specifies one of the ALIGN_* keywords, that widget will have its “natural” width. If none of the BASE_ALIGN_* or (ALIGN_*) keywords are set, all widgets in the base are as wide as their column.

### Vertical Placement

Child widgets are placed vertically one below the other, with no extra space. If the GRID_LAYOUT keyword is set, each row is as high as its tallest member.

## CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0

(zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see"Context-Sensitive Menus" in Chapter 27 of the *Building IDL Applications* manual.

## CONTEXT_MENU

Set this keyword to create a base widget that can be used as the base for a context-sensitive menu (also known as a pop-up or shortcut menu). A context menu base must have as its parent one of the following types of widgets: WIDGET_BASE, WIDGET_DRAW, WIDGET_TEXT, WIDGET_LIST.

For more on creating context menus, see "Context-Sensitive Menus" in Chapter 27 of the *Building IDL Applications* manual.

## DISPLAY_NAME

Set this keyword equal to a string that specifies the name of the X Windows display on which the base should be displayed. This keyword has no effect on Microsoft Windows platforms.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

**Note**

If you are using XMANAGER to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the EVENT_HANDLER keyword to XMANAGER.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

**Note**

If you are using XMANAGER to manage events for your widget application, you should not specify an event processing routine for the top-level base of the application using this keyword. Instead, specify the event processing routine using the EVENT_HANDLER keyword to XMANAGER.

## EXCLUSIVE

Set this keyword to specify that the base can have only button-widget children and that only one button can be set at a time. These buttons, unlike normal button widgets, have two states—set and unset.

When one exclusive button is pressed, any other exclusive buttons (in the same base) that are currently set are automatically released. Hence, only one button can ever be set at one time.

This keyword can be used to create exclusive button menus. See the CW_BGROUP and CW_PDMENU functions for high-level menu-creation utilities.

**Note**

If this keyword is set, the XOFFSET and YOFFSET keywords are ignored for any widgets in this base. Exclusive bases are always laid out in columns or rows. If neither the COLUMN nor ROW keyword is specified for an exclusive base, the base defaults to COLUMN layout.

## FLOATING

Set this keyword—along with the GROUP_LEADER keyword—to create a "floating" top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

The iconizing, layering, and destruction behavior of floating bases and their group leaders is discussed in "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2128.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GRID_LAYOUT

Set this keyword to force the base to have a grid layout, in which all rows have the same height, and all columns have the same width. The row heights and column widths are taken from the largest child widget.

## GROUP_LEADER

The widget ID of an existing widget that serves as "group leader" for the newly-created widget. Widget application hierarchies are defined by group membership relationships between top-level widget bases. When a group leader is killed, for any reason, all widgets in the group are also destroyed. Iconizing and layering behavior is discussed in "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2128.

**Note**

If you specify a floating base (created with the FLOATING keyword) as a group leader, all member bases must also have either the FLOATING or MODAL keywords set. If you specify a modal base (created with the MODAL keyword) as a group leader, all member bases must have the MODAL keyword set as well.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See the "Events Returned by Base Widgets" section below for more information.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

**Note**

A procedure specified via the CLEANUP keyword to XMANAGER will override a procedure specified for your application's top-level base with WIDGET_BASE, KILL_NOTIFY.

## MAP

Once a widget hierarchy has been realized, it can be mapped (visible) or unmapped (invisible). This keyword specifies the initial map state for the given base and its descendants. Specifying a non-zero value indicates that the base should be mapped when realized (the default). A zero value indicates that the base should be unmapped initially.

After the base is realized, its map state can be altered using the MAP keyword to the WIDGET_CONTROL procedure.

**Note**

Modal bases cannot be mapped and unmapped.

**Warning**

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This "extra" resize event is generated before any manipulation of the base widget by the user.

## MBAR

Set this keyword to a named variable to cause a menubar to be placed at the top of the base (the base must be a top-level base). The menubar is itself a special kind of base widget that can only have buttons as children. Upon return, the named variable contains the widget ID of the new menubar base. This widget ID can then be used to fill the menubar with pulldown menus. For example, the following widget creation commands first create a base with a menubar, then populate the menubar with a simple pulldown menu (CW_PDMENU could also have been used to construct the pulldown menu):

```
base = WIDGET_BASE(TITLE = 'Example', MBAR=bar)
file_menu = WIDGET_BUTTON(bar, VALUE='File', /MENU)
```

```
file_bttn1=WIDGET_BUTTON(file_menu, VALUE='Item 1',$
   UVALUE='FILE1')
file_bttn2=WIDGET_BUTTON(file_menu, VALUE='Item 2',$
   UVALUE='FILE2')
```

Note that to set X Window System resources for menubars created with this keyword, you must use the RNAME_MBAR keyword rather than the RESOURCE_NAME keyword.

If you use CW_PDMENU to create a menu for the menubar, be sure to set the MBAR keyword to that function as well.

Note also that the size returned by the GEOMETRY keyword to WIDGET_INFO does not include the size of the menubar.

**Warning**

You cannot specify both the MBAR and MODAL keywords for the same widget. Doing so will cause an error.

To apply actions triggered by menu items to widgets other than the base that includes the menubar, use the KBRD_FOCUS_EVENTS keyword to keep track of which widget has (or last had) the keyboard focus.

## MODAL

Set this keyword to create a modal dialog. Modal dialogs can have default and cancel buttons associated with them. Default buttons are highlighted by the window system and respond to a press on the “Return” or “Enter” keys as if they had been clicked on. Cancel buttons respond to a press on the “Escape” key as if they had been clicked on. See the DEFAULT_BUTTON and CANCEL_BUTTON keywords to WIDGET_CONTROL for details.

**Note**

Modal dialogs must have a group leader. Specify the group leader for a modal top-level base via the GROUP_LEADER keyword.

Modal dialogs cannot be scrollable, nor can they support menubars. Setting the SCROLL, MBAR, or APP_MBAR keywords in conjunction with the MODAL keyword will cause an error. Modal dialogs cannot be mapped or unmapped. Setting the MAP keyword on a modal base will cause an error.

**Note**

On Windows platforms, the group leader of a modal base must be realized before the modal base itself can be realized. If the group leader has not been realized, it will be realized automatically.

The iconizing, layering, and destruction behavior of modal bases and their group leaders is discussed in "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2128.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_BASE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NONEXCLUSIVE

Set this keyword to specify that the base can only have button widget children. These buttons, unlike normal button widgets, have two states—set and unset. Non-exclusive bases allow any number of the toggle buttons to be set at one time.

**Note**

If this keyword is set, the XOFFSET and YOFFSET keywords are ignored for any widgets in this base. Non-exclusive bases are always laid out in columns or rows. If neither the COLUMN nor ROW keyword is specified for a non-exclusive base, the base defaults to COLUMN layout.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. Once defined, this name can be used in the user's `.Xdefaults` file to customize widget resources not directly supported via the IDL widget routines. This keyword is accepted by all widget creation routines. This keyword only works with the "X" device and is ignored on Microsoft Windows platforms.

RESOURCE_NAME allows unrestricted access to the underlying Motif widgets within the following limitations:

- Users must have the appropriate resources defined in their `.Xdefaults` or application default resource file, or IDL will not see the definitions and they will not take effect.
- Motif resources are documented in the *OSF/Motif Programmer's Reference Manual*. To use them with RESOURCE_NAME, the IDL programmer must determine the type of widget being used by IDL, and then look up the resources that apply to them. Hence, RESOURCE_NAME requires some programmer-level familiarity with Motif.
- Only resources that are not set within IDL can be modified using this mechanism. Although it is not an error to set resources also set by IDL, the IDL settings will silently override user settings. RSI does not document the resources used by IDL since the actual resources used may differ from release to release as the IDL widgets evolve. Therefore, you should set only those resources that are obviously not being set by IDL. Among the resources that are not being set by IDL are those that control colors, menu mnemonics, and accelerator keys.

### Example

The sample code below produces a pulldown menu named “Menu” with 2 entries named “Item 1” and “Item 2”.

Using the RESOURCE_NAME keyword in conjunction with X resource definitions, we can alter “Item 1” in several ways not possible through the standard IDL widgets interface. We’ll give Item 1 a red background color. We’ll also assign “I” as the keyboard mnemonic. Note that Motif automatically underlines the “I” in the title to indicate this. We’ll also select Meta-F4 as the keyboard accelerator for selecting “Item 1”. If Meta-F4 is pressed while the pointer is anywhere over this application, the effect will be as if the menu was pulled down and “Item 1” was selected with the mouse.

```
; Simple event handler:
PRO test_event, ev
   HELP, /STRUCTURE, ev
END

; Simple widget creation routine:
PRO test

   ; The base gets the resource name "test":
   a = WIDGET_BASE(RESOURCE_NAME = 'test')
   b = WIDGET_BUTTON(a, VALUE='Menu', /MENU)

   ; Assign the Item 1 button the resource name "item1":
   c = WIDGET_BUTTON(b, VALUE='Item 1', $
      RESOURCE_NAME='item1')
   c = WIDGET_BUTTON(b, VALUE='Item 2')
   WIDGET_CONTROL, /REALIZE, a
   XMANAGER, 'test', a
END
```

Note that we gave the overall application the resource name “test”, and the “Item 1” button the resource name “item1”. Now we can use these names in the following `.Xdefaults` file entries:

```
Idl*test*item1*mnemonic: I
Idl*test*item1*accelerator: Meta<Key>F4
Idl*test*item1*acceleratorText: Meta-F4
Idl*test*item1*background: red
```

### Note on Specifying Color Resources

If you wish to specify unique colors for your widgets, it is generally a good idea to use a color name (“red” or “lightblue”, for example) rather than specifying an exact color match with a color string (such as “#b1b122222020”). If IDL is not able to

allocate an exact color, the entire operation may fail. Specifying a named color implies “closest color match,” an operation that rarely fails.

If you need an exact color match and IDL fails to allocate the color, try modifying the `Idl.colors` resource in the `$IDL_DIR/resource/X11/lib/app-defaults/Idl` file.

## RNAME_MBAR

A string containing an X Window System resource name to be applied to the menubar created by the MBAR keyword. This keyword is identical to the RESOURCE_NAME keyword except that the resource it specifies applies only to the menubar.

## ROW

If this keyword is included, the base lays out its children in rows. The value of this keyword specifies the number of rows to be used. The number of child widgets in each row is calculated by dividing the number of child widgets created by the number of rows specified. When one row is filled, a new one is started.

Specifying both the COLUMN and ROW keywords causes an error.

### Row Height

The height of each row is determined by the height of the tallest widget in that row. If the GRID_LAYOUT keyword is set, all rows are as tall as the tallest widget in the base.

### Vertical Size of Widgets

If any of the BASE_ALIGN_* keywords to WIDGET_BASE is set, each widget has its “natural” height, determined either by the value of the widget or by the YSIZE keyword. Similarly, if any of the child widgets specifies one of the ALIGN_* keywords, that widget will have its “natural” height. If none of the BASE_ALIGN_* or (ALIGN_*) keywords are set, all widgets in the base are as tall as their row.

### Horizontal Placement

Child widgets are placed horizontally one next to the other, with no extra space. If the GRID_LAYOUT keyword is set, each column is as wide as its widest member.

## SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen.

**Warning**

You cannot specify both the SCROLL and MODAL keywords for the same widget. Doing so will cause an error.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## SPACE

The space, in units specified by the UNITS keyword (pixels are the default), between children of a row or column major base. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

## TITLE

A string containing the title to be used for the widget. Base widgets use the title only if they are top-level widgets or if they are children of a tab widget. For top-level base widgets, the title appears in the “window dressing” at the top of the base widget; the appearance is platform-specific. For base widgets that have a tab widget as their parent widget, the title is used as the text of the tab.

Note that if the widget base is not wide enough to contain the specified title, the title may appear truncated. If you must be able to see the full title, you have several alternatives:

- Rearrange the widgets in the base so that the base becomes naturally wide enough. This is the best solution.
- Don’t worry about this issue. If the user needs to see the entire label, they can resize the window using the mouse.
- Create the base without using the COLUMN or ROW keywords. Instead, use the XSIZE keyword to explicitly set a usable width. This is an undesirable solution that can lead to strange-looking widget layouts.

For bases that are children of tab widgets, the title may be truncated depending on the width of the largest base that is a child of the tab widget. See the description of the MULTILINE keyword to WIDGET_TAB for additional details.

## TLB_FRAME_ATTR

Set this keyword to one of the values shown in the table below to suppress certain aspects of a top-level base’s window frame. This keyword applies only to top-level bases. The settings are merely hints to the window system and may be ignored by some window managers. Valid settings are:

| Value | Meaning |
|---|---|
| 1 | Base cannot be resized, minimized, or maximized. |
| 2 | Suppress display of system menu. |
| 4 | Suppress title bar. |
| 8 | Base cannot be closed. |
| 16 | Base cannot be moved. |

*Table 95: Valid Values for TLB_FRAME_ATTR Keyword*

This keyword is set bitwise, so multiple effects can be set by adding values together. For example, to make a base that has no title bar (value `4`) and cannot be moved (value `16`), set the TLB_FRAME_ATTR keyword to `20` (that is, `4+16`).

## TLB_ICONIFY_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is iconified or restored by the user. See the "Events Returned by Base Widgets" section below for more information.

## TLB_KILL_REQUEST_EVENTS

Set this keyword, usable only with top-level bases, to send the top-level base a WIDGET_KILL_REQUEST event if a user tries to destroy the widget using the window manager (by default, widgets are simply destroyed). See the "Events Returned by Base Widgets" section below for more information.

Use this keyword to perform complex actions before allowing a widget application to exit. Note that widgets that have this keyword set are responsible for killing themselves after receiving a WIDGET_KILL_REQUEST event—they cannot be destroyed using the usual window system controls.

Use a call to TAG_NAMES with the STRUCTURE_NAME keyword set to differentiate a WIDGET_KILL_REQUEST event from other types of widget events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
   'WIDGET_KILL_REQUEST' THEN ...
```

## TLB_MOVE_EVENTS

Set this keyword when creating a top-level base to make that base return an event when the base is moved on the screen by the user. See the "Events Returned by Base Widgets" section below for more information.

## TLB_SIZE_EVENTS

Set this keyword, when creating a top-level base, to make that base return an event when the base is resized by the user. See the "Events Returned by Base Widgets" section below for more information.

## TOOLBAR

Set this keyword to indicate that the base is used to hold bitmap buttons that make up a toolbar.

**Note**

Setting this keyword does not cause any changes in behavior; its only affect is to slightly alter the appearance of the bitmap buttons on the base for cosmetic reasons.

**Note**

On Motif platforms, if bitmap buttons are on a toolbar base that is also EXCLUSIVE or NONEXCLUSIVE, they will not have a separate “toggle” indicator, they will be grouped closely together, and will have a two-pixel shadow border.

**Note**

This keyword has no effect on Windows platforms.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer *enters* or *leaves* the region covered by that widget. Widget tracking events are returned as structures with the following definition:

```
{ WIDGET_TRACKING, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID, TOP, and HANDLER are the standard fields found in every widget event. ENTER is 1 if the tracking event is an entry event, and 0 if it is an exit event.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## XPAD

The horizontal space, in units specified by the UNITS keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of XPAD is platform dependent. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

## X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget.

Use of the X_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when X_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify Y_SCROLL_SIZE when specifying X_SCROLL_SIZE.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## YPAD

The vertical space, in units specified by the UNITS keyword (pixels are the default), between child widgets and the edges of a row or column major base. The default value of YPAD is platform-dependent. This keyword is ignored if either the EXCLUSIVE or NONEXCLUSIVE keyword is present.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

## Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget.

Use of the Y_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when Y_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify X_SCROLL_SIZE when specifying Y_SCROLL_SIZE.

## Obsolete Keywords

The following keywords are obsolete:

- APP_MBAR

For information on obsolete keywords, See Appendix I, "Obsolete Features".

# Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of base widgets. In addition to those keywords that affect all widgets, the following are particularly useful: CANCEL_BUTTON, CONTEXT_EVENTS, DEFAULT_BUTTON, KBRD_FOCUS_EVENTS, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS.

# Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to base widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: CONTEXT_EVENTS, KBRD_FOCUS_EVENTS, MODAL, TLB_ICONIFY_EVENTS, TLB_KILL_REQUEST_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS.

# Events Returned by Base Widgets

## Resize Events

Top-level widget bases return the following event structure only when they are resized by the user and the base was created with the TLB_SIZE_EVENTS keyword set:

```
{ WIDGET_BASE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The X and Y fields return the new width of the base, not including any frame provided by the window manager.

## Move Events

Top-level widget bases return the following event structure when the base is moved and the base was created with the TLB_MOVE_EVENTS keyword set:

```
{ WIDGET_TLB_MOVE, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. X and Y are the new location of the top left corner of the base.

**Note**

On Windows, move events are generated while dragging. On UNIX, move events are generated only on the mouse-up.

**Note**

If both TLB_SIZE_EVENTS and TLB_MOVE_EVENTS are enabled, a user resize operation that causes the top left corner of the base to move will generate both a move event and a resize event.

## Iconify Events

Top-level widget bases return the following event structure when the base is iconified or restored and the base was created with the TLB_ICONIFY_EVENTS keyword set:

```
{ WIDGET_TLB_ICONIFY, ID:0L, TOP:0L, HANDLER:0L, ICONIFIED:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. ICONIFIED is 1 (one) if the user iconified the base and 0 (zero) if the user restored the base.

## Keyboard Focus Events

Widget bases return the following event structure when the keyboard focus changes and the base was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The ENTER field returns 1 (one) if the base is gaining the keyboard focus, or 0 (zero) if the base is losing the keyboard focus.

## Kill Request Events

Top-level widget bases return the following event structure only when a user tries to destroy the widget using the window manager and the base was created with the TLB_KILL_REQUEST_EVENTS keyword set:

```
{ WIDGET_KILL_REQUEST, ID:0L, TOP:0L, HANDLER:0L }
```

ID is the widget ID of the base generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine.

### Context Menu Events

Base widgets return the following event structure when the user clicks the right mouse button and the base widget was created with the CONTEXT_EVENTS keyword set:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the base widget.

## Version History

Introduced: Pre 4.0

TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TOOLBAR keywords; new event structures for inconify and move events: 5.6

## See Also

Chapter 25, “Widgets” in the *Building IDL Applications* manual.

# WIDGET_BUTTON

The WIDGET_BUTTON function creates button widgets.

## Exclusive And Non-Exclusive Bases

Buttons placed into exclusive or non-exclusive bases (created via the EXCLUSIVE or NONEXCLUSIVE keywords to WIDGET_BASE function) are created as two-state “toggle” buttons, which are controlled by such bases.

## Bitmap Button Labels

Widget buttons can have either a text label (specified as a string value to the VALUE keyword) or a graphic symbol in the form of a bitmap. Bitmap labels are specified in one of the following ways:

1. By setting the VALUE keyword equal to a string containing the name of an image file in BMP format, and setting the BITMAP keyword:

   ```
   button=WIDGET_BUTTON(base, VALUE='mybitmap.bmp', /BITMAP)
   ```

   For 16- and 256-color bitmap files, IDL uses the color of the pixel in the lower left corner as the transparent color. All pixels of this color become transparent, allowing the button color to show through.

   To modify the bitmap after creation, use the /BITMAP keyword with WIDGET_CONTROL:

   ```
   WIDGET_CONTROL, button, SET_VALUE='mybitmap2.bmp', /BITMAP
   ```

2. By setting the VALUE keyword equal to an *n* x *m* bitmap byte array in which each bit represents a pixel with a value of either zero or one. (Arrays of this type can be produced using the CVTTOBM function.) This method creates a black-and-white bitmap label:

   ```
   button=WIDGET_BUTTON(base, VALUE=bw_arr)
   ```

   To modify the bitmap after creation, simply set a new value using WIDGET_CONTROL:

   ```
   WIDGET_CONTROL, button, SET_VALUE=bw_array2
   ```

3. By setting the VALUE keyword equal to an *n* x *m* x 3 byte array that represents a 24-bit color image, interleaved by plane, with the planes in the order red, green, blue. This method creates a color bitmap label:

   ```
   button=WIDGET_BUTTON(base, VALUE=color_array)
   ```

To modify the bitmap after creation, simply set a new value using WIDGET_CONTROL:

```
WIDGET_CONTROL, button, SET_VALUE=color_array2
```

See "Using Button Widgets" in Chapter 27 of the *Building IDL Applications* manual for additional details on creating image files and arrays for use as button bitmaps.

# Syntax

*Result* = WIDGET_BUTTON( *Parent* [, /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT] [, /BITMAP] [, /CHECKED_MENU] [, /DYNAMIC_RESIZE] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, /HELP] [, KILL_NOTIFY=*string*] [, /MENU] [, /NO_COPY] [, /NO_RELEASE] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, /PUSHBUTTON_EVENTS] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /SEPARATOR] [, TOOLTIP=*string*] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, X_BITMAP_EXTRA=*bits*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*] )

**X Windows Keywords:** [, RESOURCE_NAME=*string*]

# Return Value

The returned value of this function is the widget ID of the newly-created button.

# Arguments

## Parent

The widget ID of the parent for the new button widget.

# Keywords

## ALIGN_CENTER

Set this keyword to center justify the button's text label.

## ALIGN_LEFT

Set this keyword to left justify the button's text label.

## ALIGN_RIGHT

Set this keyword to right justify the button's text label.

## BITMAP

Set this keyword to specify that the bitmap specified with the VALUE keyword is a color bitmap. The value of a widget button can be a bitmap as described in "Bitmap Button Labels" on page 2151. If you specify a color bitmap with the VALUE keyword, you must also set the /BITMAP keyword.

**Note**

The use of bitmap values for menu buttons may cause unexpected behavior and is not supported.

## CHECKED_MENU

Set this keyword on a menu entry button to enable the ability to place a check (Windows) or selection box (Motif) next to the menu entry. The parent widget of the button must be either a button widget created with the MENU keyword or a base widget created with the CONTEXT_MENU keyword.

On Windows systems, a menu item that has the checked menu feature enabled but which is unselected appears just like a "normal" menu item. On Motif systems, a menu item that has the checked menu feature enabled always displays a selection box, even if the box is not selected.

**Note**

Setting this keyword does not initially "select" the menu item; selection marks are displayed and removed via the SET_BUTTON keyword to WIDGET_CONTROL.

## DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3962 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## HELP

Set this keyword to tell the widget toolkit that this button is a “help” button for a menubar and should be given that appearance. For example, Motif specifies that the help menubar item is displayed on the far right of the menubar. This keyword is ignored in all other contexts and may be ignored by window managers that have no such special appearance defined.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## MENU

The presence of this keyword indicates that the button will be used to activate a pull-down menu. Such buttons can have button children that are then placed into a pull-down menu.

Under Motif, if the value specified for MENU is greater than 1, the button label is enclosed in a box to indicate that this button is a pull-down menu. See the CW_PDMENU function for a high-level pull-down menu creation utility.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would

otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_BUTTON or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NO_RELEASE

Set this keyword to make exclusive and non-exclusive buttons generate only *select* events. This keyword has no effect on regular buttons.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## PUSHBUTTON_EVENTS

Set this keyword to cause separate button events to be issued for the widget when the left mouse button is pressed and released, or when the spacebar is pressed and released.

**Note**

This keyword has no effect on exclusive or non-exclusive buttons.

When this keyword is *not* set and the button is selected, pressing and releasing either the left mouse button or the spacebar generates a single button event, with the SELECT field set equal to 1. When this keyword *is* set:

- Pressing the left mouse button generates a button event with the SELECT field set equal to 1.
- Releasing the left mouse button generates a button event with the SELECT field set equal to 0.

- Pressing the spacebar generates a button event with the SELECT field set equal to 1 immediately followed by a second button event with the SELECT field set equal to 0.
- Pressing and holding the spacebar generates a series of button events, with the value of the SELECT field alternating between 1 and 0. The rate at which events are generated is governed by the key-repeat settings of the operating system.

For the structure of button events, see "Events Returned by Button Widgets" on page 2161.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2139 for a complete discussion of this keyword.

## SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## SEPARATOR

Set this keyword to tell the widget toolkit that this button is part of a pulldown menu pane and that a separator line should be added directly above this entry. This keyword is ignored in all other contexts.

## TOOLTIP

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

**Note**

Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.

**Note**

If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a widget button is the label for that button. You can set VALUE to any of the following:

- a string value, which displays as text;
- an *n* x *m* byte array, which displays as a black-and-white bitmap image;
- an *n* x *m* x 3 byte array, which displays as a 24-bit color bitmap image;
- if the BITMAP keyword is also specified, the name of a bitmap image file that displays as a color bitmap image of the same depth as the image in the file.

See “Bitmap Button Labels” on page 2151 for additional details on using bitmap images as button labels.

**Note**

Under Microsoft Windows, including the ampersand character (&) in the value of a button widget causes the window manager to place an underline under the character following the ampersand. (This is a feature of Microsoft Windows, and is generally used to indicate which character is used as a keyboard accelerator for the button.) If you are designing an application that will run on different platforms, you should avoid the use of the ampersand in button value strings.

## X_BITMAP_EXTRA

When creating a bitmap button that is not of a “byte-aligned” size (i.e., a dimension is not a multiple of 8), this keyword specifies how many bits of the supplied bitmap must be ignored (within the end byte). For example, to create a 10 by 8 bitmap, you need to supply a 2 by 8 array of bytes and ignore the bottom 6 bits. Therefore, you would specify `X_BITMAP_EXTRA = 6`.

### XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

### XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

### YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

### YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of button widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DYNAMIC_RESIZE, DYNAMIC_RESIZE, GET_VALUE, INPUT_FOCUS, PUSHBUTTON_EVENTS, SET_BUTTON, SET_VALUE, TOOLTIP, X_BITMAP_EXTRA.

## Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO function return information that applies specifically to button widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: BUTTON_SET, DYNAMIC_RESIZE, PUSHBUTTON_EVENTS, TOOLTIP.

## Events Returned by Button Widgets

Pressing the mouse button while the mouse cursor is over a button widget causes the widget to generate an event. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_BUTTON, ID:0L, TOP:0L, HANDLER:0L, SELECT:0}
```

ID is the widget id of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. SELECT is set to 1 if the button was set, and 0 if released. Unless the PUSHBUTTON_EVENTS keyword is set, normal buttons do not generate events when released, so SELECT will always be 1. Toggle buttons (children of either an exclusive or non-exclusive base) always return separate events for the set and release actions.

## Version History

Introduced: Pre 4.0

CHECKED_MENU and TOOLTIP keywords added: 5.6

PUSHBUTTON_EVENTS keyword added: 6.0

CW_BGROUP, CW_PDMENU

# WIDGET_COMBOBOX

The WIDGET_COMBOBOX function creates combobox widgets, which are similar to droplist widgets. The main difference between the combobox widget and the droplist widget is that the combobox widget can be created in such a way that the text field is editable, allowing the user to enter a value that is not on the list.

A combobox widget displays a text field and an arrow button. If the combobox is not editable, selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently-selected option. This action generates an event containing the index of the selected item, which ranges from zero to the number of elements in the list minus one.

If the combobox is editable, text can be entered in the text box without causing the list to drop down. This action causes an event in which the index field is set to -1, allowing you to distinguish this event from list selections.

The text of the current selection is returned in the STR field of the WIDGET_COMBOBOX event structure. See "Widget Events Returned by Combobox Widgets" on page 2169 for details.

**Note**

WIDGET_COMBOBOX is not currently available on Compaq True64 UNIX platforms due to that platform's lack of support for the necessary Motif libraries.

## Syntax

*Result* = WIDGET_COMBOBOX( *Parent* [, /DYNAMIC_RESIZE] [, /EDITABLE] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*] [, FRAME=*value*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*] )

## Return Value

The returned value of this function is the widget ID of the newly-created combobox widget.

# Arguments

## Parent

The widget ID of the parent widget for the new combobox widget.

# Keywords

## DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed.

**Note**

This keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

## EDITABLE

Set this keyword to create an editable combobox. If the combobox is editable, users can enter or modify in the text field. Changes in the combobox text field will cause combobox events with the INDEX field of the event structure set to -1. The current text will be ‘ in the STR field of the event structure.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3962 in the *IDL Reference Guide* for

details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget.

**Note**

This keyword is only a hint to the toolkit, and may be ignored in some instances.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string ( ' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are

disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_COMBOBOX or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “RESOURCE_NAME” on page 2139 in the *IDL Reference Guide* for a complete discussion of this keyword.

## SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

**Note**

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a combobox widget is a scalar string or array of strings that contains the text of the list items (one list item per array element). Combobox widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

**Note**

Null strings are not allowed in the combobox widget item list.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

### XSIZE

The desired width of the combobox widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

### YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

### YSIZE

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the combobox button or of the dropped list. Instead, it controls the size around the combobox button and, as such, is not particularly useful.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of combobox widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: COMBOBOX_ADDITEM, COMBOBOX_DELETEITEM, COMBOBOX_INDEX, DYNAMIC_RESIZE, GET_VALUE, SET_COMBOBOX_SELECT, SET_VALUE.

## Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO return information that applies specifically to combobox widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: COMBOBOX_GETTEXT, COMBOBOX_NUMBER, DYNAMIC_RESIZE.

## Widget Events Returned by Combobox Widgets

Pressing the mouse button while the mouse pointer is over an element of a combobox widget causes the widget to change the text field on the combobox and to generate an event. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_COMBOBOX, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, STR:""}
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This can be used to index the array of names originally used to set the widget's value. If the event was caused by text changes in an editable combobox, the INDEX field will be set to -1. If you are using an editable combobox, it is important to check for the value of -1 prior to using the value of the INDEX field as an index into the array if items. The text of the current selection is returned in the STR field, which may eliminate the need to use the index field in many cases.

**Note**

Platform-specific UI toolkits behave differently if a combobox widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

## Version History

Introduced: 5.6

CW_PDMENU, WIDGET_BUTTON, WIDGET_DROPLIST, WIDGET_LIST

# WIDGET_CONTROL

The WIDGET_CONTROL procedure is used to realize, manage, and destroy widget hierarchies. It is often used to change the default behavior or appearance of previously-realized widgets.

## Syntax

WIDGET_CONTROL [, *Widget_ID*]

**Keywords that apply to all widgets:** [, BAD_ID=*variable*] [, /CLEAR_EVENTS] [, DEFAULT_FONT=*string*{do not specify *Widget_ID*}] [, /DELAY_DESTROY{do not specify *Widget_ID*}] [, /DESTROY] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FUNC_GET_VALUE=*string*] [, GET_UVALUE=*variable*] [, GROUP_LEADER=*widget_id*] [, /HOURGLASS{do not specify *Widget_ID*}] [, KILL_NOTIFY=*string*] [, /MAP] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, /REALIZE] [, /RESET{do not specify *Widget_ID*}] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, SEND_EVENT=*structure*] [, /SENSITIVE] [, SET_UNAME=*string*] [, SET_UVALUE=*value*] [, /SHOW] [, TIMER=*value*] [, TLB_GET_OFFSET=*variable*] [, TLB_GET_SIZE=*variable*] [, /TLB_KILL_REQUEST_EVENTS] [, TLB_SET_TITLE=*string*] [, TLB_SET_XOFFSET=*value*] [, TLB_SET_YOFFSET=*value*] [, /TRACKING_EVENTS] [, UNITS={0 | 1 | 2}] [, /UPDATE] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*]

**Keywords that apply to widgets created with WIDGET_ACTIVEX:** [, GET_VALUE=*value*]

**Keywords that apply to widgets created with WIDGET_BASE:** [, BASE_SET_TITLE=*string*] [, CANCEL_BUTTON=*widget_id*{for modal bases}] [, /CONTEXT_EVENTS] [, DEFAULT_BUTTON=*widget_id*{for modal bases}] [, /ICONIFY] [, /KBRD_FOCUS_EVENTS] [, /TLB_ICONIFY_EVENTS] [, /TLB_KILL_REQUEST_EVENTS] [, /TLB_MOVE_EVENTS] [, /TLB_SIZE_EVENTS]

**Keywords that apply to widgets created with WIDGET_BUTTON:** [, /BITMAP] [, /DYNAMIC_RESIZE] [, GET_VALUE=*value*] [, /INPUT_FOCUS] [, /PUSHBUTTON_EVENTS] [, /SET_BUTTON] [, SET_VALUE=*val*ue] [, TOOLTIP=*string*] [, X_BITMAP_EXTRA=*bits*]

**Keywords that apply to widgets created with WIDGET_COMBOBOX:**
[, COMBOBOX_ADDITEM=*string*] [, COMBOBOX_DELETEITEM=*integer*]
[, COMBOBOX_INDEX=*integer*] [, ./DYNAMIC_RESIZE]
[, GET_VALUE=*value*] [, SET_COMBOBOX_SELECT=*integer*]
[, SET_VALUE=*value*]

**Keywords that apply to widgets created with WIDGET_DRAW:**
[, /DRAW_BUTTON_EVENTS] [, /DRAW_EXPOSE_EVENTS]
[, DRAW_KEYBOARD_EVENTS={0 | 1 | 2}] [, /DRAW_MOTION_EVENTS]
[, /DRAW_VIEWPORT_EVENTS] [, DRAW_XSIZE=*integer*]
[, DRAW_YSIZE=*integer*] [, GET_DRAW_VIEW=*variable*]
[, GET_UVALUE=*variable*] [, GET_VALUE=*variable*] [, /INPUT_FOCUS]
[, SET_DRAW_VIEW=*[x, y]*] [, TOOLTIP=*string*]

**Keywords that apply to widgets created with WIDGET_DROPLIST:**
[, /DYNAMIC_RESIZE] [, GET_VALUE=*variable*]
[, SET_DROPLIST_SELECT=*integer*] [, SET_VALUE=*value*]

**Keywords that apply to widgets created with WIDGET_LABEL:**
[, /DYNAMIC_RESIZE] [, GET_VALUE=*value*] [, SET_VALUE=*value*]

**Keywords that apply to widgets created with WIDGET_LIST:**
[, /CONTEXT_EVENTS] [, SET_LIST_SELECT=*value*]
[, SET_LIST_TOP=*integer*] [, SET_VALUE=*value*]

**Keywords that apply to widgets created with WIDGET_PROPERTYSHEET:**
[, REFRESH_PROPERTY=*string*, *array of strings*, or *integer*]

**Keywords that apply to widgets created with WIDGET_SLIDER:**
[, GET_VALUE=*value*] [, SET_SLIDER_MAX=*value*]
[, SET_SLIDER_MIN=*value*] [, SET_VALUE=*value*]

**Keywords that apply to widgets created with WIDGET_TAB:**
[, SET_TAB_CURRENT=*index*] [, SET_TAB_MULTILINE=*value*]

**Keywords that apply to widgets created with WIDGET_TABLE:**
[, ALIGNMENT={0 | 1 | 2}] [, /ALL_TABLE_EVENTS] [, AM_PM=*[string, string]*] [, COLUMN_LABELS=*string_array*] [, COLUMN_WIDTHS=*array*]
[, DAYS_OF_WEEK=*string_array*{7 names}] [, /DELETE_COLUMNS{not for row_major mode}] [, /DELETE_ROWS{not for column_major mode}]
[, /EDITABLE] [, EDIT_CELL=*[integer, integer]*] [, FORMAT=*value*]
[, GET_VALUE=*variable*] [, INSERT_COLUMNS=*value*]
[, INSERT_ROWS=*value*] [, /KBRD_FOCUS_EVENTS]
[, MONTHS=*string_array*{12 names}] [, ROW_LABELS=*string_array*]
[, ROW_HEIGHTS=*array*] [, SET_TABLE_SELECT=*[left, top, right, bottom]*]
[, SET_TABLE_VIEW=*[integer, integer]*] [, SET_TEXT_SELECT=*[integer,*

*integer]*] [, SET_VALUE=*value*] [, /TABLE_BLANK=*cells*]
[, /TABLE_DISJOINT_SELECTION] [, TABLE_XSIZE=*columns*]
[, TABLE_YSIZE=*rows*] [, /USE_TABLE_SELECT | ,
USE_TABLE_SELECT=*[left, top, right, bottom]*] [, /USE_TEXT_SELECT]

**Keywords that apply to widgets created with WIDGET_TEXT:**
[, /ALL_TEXT_EVENTS] [, /APPEND] [, /CONTEXT_EVENTS] [, /EDITABLE]
[, GET_VALUE=*variable*] [, /INPUT_FOCUS] [, /KBRD_FOCUS_EVENTS]
[, /NO_NEWLINE] [, SET_TEXT_SELECT=*[integer, integer]*]
[, SET_TEXT_TOP_LINE=*line_number*] [, SET_VALUE=*value*]
[, /USE_TEXT_SELECT]

**Keywords that apply to widgets created with WIDGET_TREE:**
[, SET_TREE_BITMAP=*array*] [, /SET_TREE_EXPANDED]
[, SET_TREE_SELECT={0 | 1 | *widget ID* | *array of widget IDs*}]
[, /SET_TREE_VISIBLE]

# Arguments

## Widget_ID

The widget ID of the widget to be manipulated. This argument is required by all operations, unless the description of the specific keyword states otherwise. Note that if *Widget_ID* is not provided for a keyword that needs it, that keyword is quietly ignored.

# Keywords

Not all keywords to WIDGET_CONTROL apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

## ALIGNMENT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a scalar, 2-D array, or 1-D array specifying the alignment of the contents of each cell. An alignment of 0 (the default) aligns the left edge of the text with the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in text centered within the cell.

If the USE_TABLE_SELECT keyword is not set:

- If ALIGNMENT is set equal to a scalar, all table cells are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each table cell is governed by the corresponding element of the array.

If the USE_TABLE_SELECT keyword is set:

- In standard selection mode, if ALIGNMENT is set equal to a scalar, all cells in the selection are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each selected cell is governed by the corresponding element of the array.
- In disjoint selection mode, if ALIGNMENT is set equal to a scalar, all cells in the selection are aligned as specified. If ALIGNMENT is set equal to a 1-D array, the alignment of each selected cell is governed by the corresponding element of the array.

## ALL_TABLE_EVENTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to cause to the table widget to generate events whenever the user changes the contents of a table cell.

**Note**

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. End-of-line events such as these could be used by the programmer as an indication to check the cell value or to set the currently selected cell to the next cell. See the table below for details on the interaction between ALL_TABLE_EVENTS and EDITABLE.

| Keywords | | Effects | |
|---|---|---|---|
| **ALL_TABLE_EVENTS** | **EDITABLE** | **Input changes widget contents?** | **Type of events generated** |
| Not set | Not set | No | None |
| Not set | Set | Yes | End-of-line insertion |

*Table 96: Effects of using the ALL_TABLE_EVENTS and EDITABLE keywords*

| Keywords | | Effects | |
|---|---|---|---|
| **ALL_TABLE_EVENTS** | **EDITABLE** | **Input changes widget contents?** | **Type of events generated** |
| Set | Not set | No | All events |
| Set | Set | Yes | All events |

*Table 96: Effects of using the ALL_TABLE_EVENTS and EDITABLE keywords*

## ALL_TEXT_EVENTS

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to cause to the text widget to generate events whenever the user changes the contents of the text area.

**Note**

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_TEXT_EVENTS and EDITABLE.

| Keywords | | Effects | |
|---|---|---|---|
| **ALL_TEXT_EVENTS** | **EDITABLE** | **Input changes widget contents?** | **Type of events generated** |
| Not set | Not set | No | None |
| Not set | Set | Yes | End-of-line insertion |
| Set | Not set | No | All events |
| Set | Set | Yes | All events |

*Table 97: Effects of using the ALL_TEXT_EVENTS and EDITABLE keywords*

## AM_PM

This keyword applies to widgets created with the WIDGET_TABLE function.

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

## APPEND

This keyword applies to widgets created with the WIDGET_TEXT function.

When using the SET_VALUE keyword to set the contents of a text widget (as created with the WIDGET_TEXT procedure), setting this keyword indicates that the supplied text should be appended to the existing contents of the text widget rather than replace it.

## BAD_ID

This keyword applies to all widgets.

If *Widget_ID* is not a valid widget identifier, this WIDGET_CONTROL normally issues an error and causes program execution to stop. However, if BAD_ID is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

## BASE_SET_TITLE

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to a scalar string to change the title of the specified base widget. If the parent of the base widget is a tab widget, the title of the corresponding tab in the tab widget is changed to the provided string. If the parent is not a tab control, this keyword behaves like the keyword TLB_SET_TITLE.

## CANCEL_BUTTON

This keyword applies to widgets created with the WIDGET_BASE function using the MODAL keyword.

Set this keyword equal to the widget ID of a button widget that will be the cancel button on a modal base widget.

On Motif and Windows platforms, selecting **Close** from the system menu (generally located at the upper left of the base widget) generates a button event for the **Cancel** button.

## CLEAR_EVENTS

This keyword applies to all widgets.

If set, any events generated by the widget hierarchy rooted at *Widget_ID* which have arrived but have not been processed (via the WIDGET_EVENT procedure) are discarded.

## COLUMN_LABELS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to an array of strings to be used as labels for the columns of the table. If no label is specified for a column, it receives the default label "*n*" where *n* is the column number. If this keyword is set to the empty string (''), all column labels are set to be empty.

## COLUMN_WIDTHS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a one-dimensional array of widths for the columns of the table widget. The widths are given in the units specified with the UNITS keyword. If no width is specified for a column, that column is set to the default size, which varies by platform. If COLUMN_WIDTHS is set to a scalar value, all of the column widths are set to that value.

If the USE_TABLE_SELECT keyword is set (in either standard or disjoint selection mode), the indices of the elements of an array specified as the value of the COLUMN_WIDTHS keyword are interpreted as indices into the list of selected columns. For example, if the table is in disjoint selection mode, the current selection includes cells from columns `0`, `1`, `2`, `5`, `6`, and `7`, USE_TABLE_SELECT is set equal to one, and the COLUMN_WIDTHS keyword is set equal to a four-element array `[20, 35, 30, 35]`, the widths of columns `0`, `1`, `2`, and `5` would be modified. Similarly, if the table is in standard selection mode and the USE_TABLE_SELECT keyword is set equal to the array `[0, 1, 0, 0]`, and the COLUMN_WIDTHS keyword is set equal to a four-element array `[20, 35, 30, 35]`, only the width of the first column would be altered.

## COMBOBOX_ADDITEM

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to a non-null string that specifies a new item to add to the list of the combobox. By default, the item will be added to the end of the list. The item can be added to a specified position in the list by setting the COMBOBOX_INDEX keyword in the same call to WIDGET_CONTROL.

## COMBOBOX_DELETEITEM

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to an integer that specifies the zero-based index of the combobox element to be deleted from the list. If the specified element is outside the range of existing elements, no element is deleted.

## COMBOBOX_INDEX

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to an integer that specifies the zero-based index of the position at which a new item will be added to the list when using the COMBOBOX_ADDITEM keyword. The value -1 is a special case that indicates the item should be added to the end of the list. Note that this special case is provided for convenience, and that an item can also be added to the end of the list by omitting the COMBOBOX_INDEX keyword entirely. If the supplied index is not -1, and is outside the range of zero to the length of the existing list, the item is not added to the list.

**Note**

You can retrieve the length of the existing list using the COMBOBOX_NUMBER keyword to WIDGET_INFO function.

## CONTEXT_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function, WIDGET_LIST, and WIDGET_TEXT function.

Set this keyword to cause *context menu events* (or simply *context events*) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

**Note**

You can also capture right mouse button events generated within draw widgets. See the BUTTON_EVENTS keyword to WIDGET_DRAW function for details.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 27 of the *Building IDL Applications* manual.

## DAYS_OF_WEEK

This keyword applies to widgets created with the WIDGET_TABLE function.

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

## DEFAULT_BUTTON

This keyword applies to widgets created with the WIDGET_BASE function using the MODAL keyword.

Set this keyword equal to the widget ID of a button widget that will be the default button on a modal base widget. The default button is highlighted by the window system.

## DEFAULT_FONT

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

A string containing the name of the default font to be used.

If the font to be used for a given widget is not explicitly specified (via the FONT keyword to the widget creation function), a default supplied by the window system or server is used. Use this keyword to change the default. See "About Device Fonts" on page 3962 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

## DELAY_DESTROY

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Normally, when the user destroys a widget hierarchy using the window manager, it is immediately removed. This can cause problems for applications that use the background task facility provided by the XMANAGER procedure if the hierarchy is destroyed while a background task is using it.

If DELAY_DESTROY is set, attempts to destroy the hierarchy are delayed until the next attempt to obtain an event for it. Setting DELAY_DESTROY to zero restores the default behavior.

XMANAGER uses this keyword automatically when managing background tasks. It is not expected that applications will need to use it directly.

## DELETE_COLUMNS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to delete columns that contain selected cells. If a selection is specified via the USE_TABLE_SELECT keyword (in either standard or disjoint mode), the columns that contain cells specified in the selection array are deleted. If the USE_TABLE_SELECT keyword is *either* absent or set equal to 1, the columns that contain selected cells are deleted.

**Warning**

You cannot delete columns from a table which displays structure data in /ROW_MAJOR mode (the default).

## DELETE_ROWS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to delete rows that contain selected cells. If a selection is specified via the USE_TABLE_SELECT keyword (in either standard or disjoint mode), the rows that contain cells specified in the selection array are deleted. If the USE_TABLE_SELECT keyword is *either* absent or set equal to 1, the columns that contain selected cells are deleted.

**Warning**

You cannot delete rows from a table which displays structure data in /COLUMN_MAJOR mode.

## DESTROY

This keyword applies to all widgets.

Set this keyword to destroy the widget and any child widgets in its hierarchy. Any further attempts to use the IDs for these widgets will cause an error.

## DRAW_BUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable button press events for draw widgets. Setting a zero value disables such events.

**Note**

You can use button events generated by draw widgets to simulate the functionality of the CONTEXT_EVENTS keyword to WIDGET_BASE, WIDGET_LIST, and WIDGET_TEXT. See the BUTTON_EVENTS keyword to WIDGET_DRAW for details.

## DRAW_EXPOSE_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable viewport expose events for draw widgets. Setting a zero value disables such events.

**Note**

You must explicitly disable backing store (by setting the RETAIN keyword to WIDGET_DRAW equal to zero) in order to generate expose events.

## DRAW_KEYBOARD_EVENTS

This keyword applies to widgets created with WIDGET_DRAW.

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the `CH` or the `KEY` field of the event structure, depending on the type of key pressed. See “Widget Events Returned by Draw Widgets” on page 2224 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a “normal” key is pressed. “Normal” keys include all keys except function keys and the modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the `MODIFIERS` field of the event structure.
- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the `KEY` field of the event structure, and the `MODIFIERS` field contains zero.

**Note**

Keyboard events are never generated for function keys.

## DRAW_MOTION_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable motion events for draw widgets. Setting a zero value disables such events.

## DRAW_VIEWPORT_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to enable viewport motion events for draw widgets. Setting a zero value disables such events.

## DRAW_XSIZE

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to an integer that specifies the new horizontal size for the graphics region (the *virtual size*) of a draw widget in units specified by the UNITS keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting SCR_XSIZE or XSIZE. However, for scrolling draw widgets DRAW_XSIZE is the only way to change the width of the drawable area (XSIZE sets the viewport size).

## DRAW_YSIZE

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to an integer that specifies the new vertical size for the graphics region (the *virtual size*) of a draw widget in units specified by the UNITS keyword (pixels are the default). For non-scrollable draw widgets, setting this keyword is the same as setting SCR_YSIZE or YSIZE. However, for scrolling draw widgets DRAW_YSIZE is the only way to change the height of the drawable area (YSIZE sets the viewport size).

## DYNAMIC_RESIZE

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, and WIDGET_LABEL functions.

Set this keyword to activate (if set to 1) or deactivate (if set to 0) dynamic resizing of the specified WIDGET_BUTTON, WIDGET_LABEL, or WIDGET_DROPLIST

widget (see the documentation for the DYNAMIC_RESIZE keyword to those procedures for more information about dynamic widget resizing).

## EDITABLE

This keyword applies to widgets created with the WIDGET_TABLE and WIDGET_TEXT functions.

Set this keyword to allow direct user editing of the contents of a text or table widget. Normally, the text in text and table widgets is read-only. See the descriptions of the ALL_TABLE_EVENTS and ALL_TEXT_EVENTS keywords for additional details.

## EDIT_CELL

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a two-element integer array containing the y (row) and x (column) coordinates of a table cell to put that cell into edit mode. For example, to put the top cell in the third column (x index=2) into edit mode, use the following commands:

```
row=0
col=2
WIDGET_CONTROL, table, EDIT_CELL=[row, col]
```

where *table* is the Widget ID of the table widget.

## EVENT_FUNC

This keyword applies to all widgets.

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy given by *Widget_ID*.

This keyword overwrites any event routine supplied by previous uses of the EVENT_FUNC or EVENT_PRO keywords. To specify no event routine, set this keyword to a null string (`''`).

## EVENT_PRO

This keyword applies to all widgets.

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy given by *Widget_ID*.

This keyword overwrites any event routine supplied by previous uses of the EVENT_FUNC or EVENT_PRO keywords. To specify no event routine, set this keyword to a null string (' ').

## FORMAT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a single string or a one- or two-dimensional array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the FORMAT keyword to the PRINT procedure, and the default format is the same as that used by the PRINT/PRINTF procedures.

If the USE_TABLE_SELECT keyword is set equal to one, the format is changed only for the currently selected cells. If USE_TABLE_SELECT is set equal to an array, the format is changed for the specified cells.

- In standard selection mode, FORMAT can be set either to a single string or to a two-dimensional array of strings of the same size as the selected area.
- In disjoint selection mode, FORMAT can be set either to a single string or to a one-dimensional array of strings with the same number of elements as the selected area.

## FUNC_GET_VALUE

This keyword applies to all widgets.

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. The function specified by FUNC_GET_VALUE is called with the widget ID as an argument. The function specified by FUNC_GET_VALUE should return a value for a widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GET_DRAW_VIEW

This keyword applies to widgets created with the WIDGET_DRAW function.

Specifies a named variable which will be assigned the current position of a draw widget viewport. The position is returned as a 2-element integer array giving the X and Y position relative to the lower left corner of the graphics area.

## GET_UVALUE

This keyword applies to all widgets.

Set this keyword to a named variable to contain the current user value of the widget.

Each widget can contain a user set value of any data type and organization. This value is not used by the widget in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to obtain the current user value.

The user value of a widget can be set with the SET_UVALUE keyword to this routine, or with the UVALUE keyword to the routine that created it.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword (described below) with GET_UVALUE.

## GET_VALUE

This keyword applies to widgets created with the WIDGET_ACTIVEX, WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DRAW, WIDGET_DROPLIST, WIDGET_LABEL, WIDGET_SLIDER, WIDGET_TABLE, and WIDGET_TEXT functions.

**Note**

If you would like information about the values returned for a specific compound widget—beginning with the prefix “CW_”—please refer to the description of the compound widget, which may also include a section titled, “Keywords to WIDGET_CONTROL and WIDGET_INFO”. Compound widgets are described in the *Reference Guide*.

Set this keyword to a named variable to contain the current value of the widget. The type of value returned depends on the widget type:

- ActiveX: An object reference to the IDLcomActiveX object that underlies the ActiveX widget. See Chapter 5, “Using ActiveX Controls in IDL” in the *External Development Guide* manual for details.
- Button: If the button label is text, it is returned as a string. Attempts to obtain the value of a button with a bitmap label is an error.
- Combobox: The contents of the list of the combobox widget are returned as a string or string array.
- Draw: The value of a draw widget depends on whether the draw widget uses IDL Direct Graphics or IDL Object Graphics. (The type of graphics used is specified by the GRAPHICS_LEVEL keyword to WIDGET_DRAW.) The two possibilities are:

  A. By default, draw widgets use IDL Direct Graphics. In this case, the value of a draw widget is the IDL window ID for the drawing area. This ID is

used with procedures such as WSET, WSHOW, etc., to direct graphics to the widget. The window ID is assigned to drawing area widgets at the time they are realized. If the widget has not yet been realized, a value of -1 is returned.

B. If the draw widget uses IDL Object Graphics (that is, if the GRAPHICS_LEVEL keyword to WIDGET_DRAW is set equal to 2), the value of the draw widget is the object reference of the window object used in the draw widget.

- Droplist: The contents of the droplist widget's list are returned as a string or string array.
- Label: The label text is returned as a string.
- Property Sheet: Retrieves the component object(s) that the property sheet is associated with. Use the GET_VALUE keyword to WIDGET_CONTROL.
- Slider: The current value of the slider is returned as an integer.
- Table: Normally, the data for the whole table are returned as a two dimensional array or a vector of structures.

  If the USE_TABLE_SELECT keyword is set, the value returned is a subset of the whole data.

  - If the table is in standard selection mode and the table data is of a single type, the value returned is a two dimensional array. If the table contains structure data, the value returned is a vector of (possibly anonymous) structures.
  - If the table is in disjoint selection mode and the table data is a single type, the value returned is a one-dimensional array of values. If the table contains structure data, the value returned is a single structure in which each field corresponds to a selected cell. In either case, use the TABLE_SELECT keyword to WIDGET_INFO to get the row and column indices of the disjoint values.

  If the USE_TEXT_SELECT keyword is set, the value returned is a string corresponding to the currently-selected text in the currently-selected cell.
- Text: The current contents of the text widget are returned as a string array. If the USE_TEXT_SELECT keyword is also specified, only the contents of the current selection are returned.
- Widget types not listed above do not return a value. Attempting to retrieve the value of such a widget causes an error.

The value of a widget can be set with the SET_VALUE keyword to this routine, or with the VALUE keyword to the routine that created it.

## GROUP_LEADER

This keyword applies to all widgets.

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## HOURGLASS

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword.

Set this keyword to turn on an “hourglass-shaped” cursor for all IDL widgets and graphics windows. The hourglass remains in place until the WIDGET_EVENT function attempts to process the next event. Then the previous cursor is reinstated. If an application starts a time-intensive calculation inside an event-handling routine, the hourglass cursor should be used to indicate that the system is not currently responding to events.

## ICONIFY

This keyword applies to all widgets.

Set this keyword to a non-zero value to cause the specified widget to become iconified. Set this keyword to zero to open an iconified widget.

## INPUT_FOCUS

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_DRAW, and WIDGET_TEXT functions.

If *Widget_ID* is a text widget, you can set this keyword to cause the widget to receive the keyboard focus. If *Widget_ID* is a button widget, set this keyword to position the mouse pointer over the button (on Motif), or set the focus to the button so that it can be “pushed” with the spacebar (on Windows). This keyword has no effect for other widget types.

**Note**

You cannot assign the input focus to an unrealized widget.

## INSERT_COLUMNS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to the number of columns to be added to the right of the rightmost column of the table. If the USE_TABLE_SELECT keyword is set equal to one, the columns are inserted to the left of the current selection. If USE_TABLE_SELECT is set equal to an array, the columns are inserted to the left of the specified selection.

**Warning**

You cannot insert columns into a table which displays structure data in /ROW_MAJOR (default) mode because it would change the structure.

## INSERT_ROWS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to the number of rows to be added below the bottommost row of the table. If the USE_TABLE_SELECT keyword is set equal to one, the rows are inserted above the current selection. If USE_TABLE_SELECT is set equal to an array, the rows are inserted above the specified selection.

**Warning**

You cannot insert rows into a table which displays structure data in /COLUMN_MAJOR mode because it would change the structure.

## KBRD_FOCUS_EVENTS

This keyword applies to widgets created with the WIDGET_BASE, WIDGET_TABLE, and WIDGET_TEXT functions.

Set this keyword to cause widget keyboard focus events to be issued for the widget whenever the keyboard focus of that widget changes. See the KBRD_FOCUS_EVENTS keywords to WIDGET_BASE, WIDGET_TABLE, and WIDGET_TEXT for details.

## KILL_NOTIFY

This keyword applies to all widgets.

Use this keyword to change or remove a previously-specified callback procedure for *Widget_ID*. A previously-defined callback can be removed by setting this keyword to the null string ( ' ').

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

For a top-level base widget in a widget application, the CLEANUP keyword to XMANAGER can also be used to specify a procedure that will be called when the base widget dies. Note that the *last* call to any of:

- WIDGET_BASE, KILL_NOTIFY
- XMANAGER, CLEANUP
- WIDGET_CONTROL, KILL_NOTIFY

determines the procedure that is executed when the specified top-level base widget dies. Calling XMANAGER with the CLEANUP keyword overrides any previous setting of KILL_NOTIFY. Similarly, calling WIDGET_CONTROL with KILL_NOTIFY overrides any previous setting of CLEANUP.

## MANAGED

This keyword applies to all widgets.

This keyword is used by the XMANAGER procedure to mark those widgets that it is currently managing. User applications should not use this keyword directly.

## MAP

This keyword applies to all widgets.

Set this keyword to zero to unmap the widget hierarchy rooted at the widget specified by *Widget_ID*. The hierarchy disappears from the screen, but still exists.

The mapping operation applies only to base widgets. If the specified widget is not a base, IDL searches upward in the widget hierarchy until it finds the closest base widget. The map operation is applied to that base.

Set MAP to a nonzero value to re-map the widget hierarchy and make it visible. Normally, the widget is automatically mapped when it is realized, so use of the MAP keyword is not required.

## MONTHS

This keyword applies to widgets created with the WIDGET_TABLE function.

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

## NO_COPY

This keyword applies to all widgets.

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

**Note**

The NO_COPY keyword increases efficiency when sending event structures using the SEND_EVENT keyword to WIDGET_CONTROL.

## NO_NEWLINE

This keyword applies to widgets created with the WIDGET_TEXT function.

When setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. The NO_NEWLINE keyword suppresses this action.

## NOTIFY_REALIZE

This keyword applies to all widgets.

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once

(because widgets are realized only once). Each widget is allowed a single such "callback" procedure. A previously-set callback routine can be removed by setting this keyword to the null string ( ' ' ). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

This keyword applies to all widgets.

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. The procedure specified by PRO_SET_VALUE is called with 2 arguments— a widget ID and a value. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## PUSHBUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_BUTTON function.

Set this keyword to a non-zero value to enable pushbutton events for the widget specified by *Widget_ID*. Set the keyword to 0 to disable pushbutton events for the specified widget. For a description of pushbutton events, see "PUSHBUTTON_EVENTS" on page 2156 in the documentation for WIDGET_BUTTON.

## REALIZE

This keyword applies to all widgets.

If set, the widget hierarchy is realized. Until the realization step, the widget hierarchy exists only within IDL. Realization is the step of actually creating the widgets on the screen (and mapping them if necessary).

When a previously-realized widget gets a new child widget, the new child is automatically realized.

**Tip**

Under Microsoft Windows, when a hidden base is realized, then mapped, a Windows resize message is sent by the windowing system. This "extra" resize event is generated before any manipulation of the base widget by the user.

## REFRESH _PROPERTY

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function. Set this keyword to a property identifier or array of property identifiers to

have just those properties synchronized with their values in the component(s). Recall that property identifiers are strings that uniquely determine a property. The keyword can also be set to a numeric value—non-zero values refresh all properties. The REFRESH_PROPERTY keyword also updates with respect to a property's sensitivity and visibility.

When all properties need synchronizing, it is more efficient to use /REFRESH_PROPERTY than WIDGET_CONTROL's SET_VALUE keyword to reload the property sheet.

## RESET

This keyword applies to all widgets. Do not specify a *Widget ID* when using this keyword. Set the RESET keyword to destroy every currently active widget. This keyword should be used with caution.

## ROW_LABELS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label "*n*" where *n* is the row number. If this keyword is set to the empty string (''), all row labels are set to be empty.

## ROW_HEIGHTS

This keyword applies to widgets created with the WIDGET_TABLE function.

**Note**

This keyword is not supported under Microsoft Windows.

Set this keyword equal to a one-dimensional array of heights for the rows of the table widget. The heights are given in the units specified with the UNITS keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If ROW_HEIGHTS is set to a scalar value, all of the row heights are set to that value.

If the USE_TABLE_SELECT keyword is set (in either standard or disjoint selection mode), the indices of the elements of the specified array are interpreted as indices into the list of selected columns. For example, if the table is in disjoint selection mode, the current selection includes cells from rows `0`, `1`, `2`, `5`, `6`, and `7`, USE_TABLE_SELECT is set equal to one, and the ROW_HEIGHTS keyword is set equal to a four-element array `[20, 35, 30, 35]`, the height of rows `0`, `1`, `2`, and `5` would be modified. Similarly, if the table is in standard selection mode and the

USE_TABLE_SELECT keyword is set equal to the array `[0, 1, 0, 0]`, and the ROW_HEIGHTS keyword is set equal to a four-element array `[20, 35, 30, 35]`, only the height of the first row would be altered.

## SCR_XSIZE

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new horizontal size, in units specified by the UNITS keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area).

## SCR_YSIZE

This keyword applies to all widgets.

Set this keyword to an integer value that represents the widget's new vertical size, in units specified by the UNITS keyword (pixels are the default). Attempting to change the size of a widget that is part of a menubar or pulldown menu causes an error. This keyword is useful for resizing table, text, list, and scrolling widgets. Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area).

## SEND_EVENT

This keyword applies to all widgets.

Set this keyword to a structure containing a valid widget event to be sent to the specified widget. The value of SEND_EVENT *must* be a structure and the first three fields must be ID, TOP, and HANDLER (all of LONG type). Additional fields can be of any type.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword with SEND_EVENT.

## SENSITIVE

Set this keyword to control the sensitivity state of a widget after creation. This keyword applies to all widgets. Use the SENSITIVE keyword with the widget creation function to control the initial sensitivity state.

When a widget is sensitive, it has normal appearance and can receive user input. For instance, a sensitive button widget can be activated by moving the mouse cursor over

it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, and ignores any input directed at it. If SENSITIVE is zero, the widget hierarchy becomes insensitive. If nonzero, it becomes sensitive.

Sensitivity can be used to control when a user is allowed to manipulate a widget. It should be noted that some widgets do not change their appearance when they are made insensitive, and simply cease generating events.

## SET_BUTTON

This keyword applies to widgets created with the WIDGET_BUTTON function.

This keyword changes the current state of toggle buttons. If set equal to zero, every toggle button in the hierarchy specified by *Widget_ID* is set to the unselected state. If set to a nonzero value, the action depends on the type of base holding the buttons:

- For a non-exclusive base:
  - If a single button is specified by *Widget_ID*, that button is set to the selected state, leaving the state of other buttons in the base unchanged.
  - If the base itself is specified by *Widget_ID*, all buttons are set to the selected state.
- For an exclusive base:
  - If a single button is specified by *Widget_ID*, that button is set to the selected state, and all other buttons in the base are set to the unselected state.
  - If the base itself is specified by *Widget_ID*, IDL generates an error, since an exclusive base can contain at most one selected button.

If the specified *Widget_ID* is a button widget that was created using the CHECKED_MENU keyword, the checked state of the menu item is modified. If the keyword value is nonzero, the menu button is placed in a checked state. If the keyword value is zero, the button is placed in a un-checked state.

## SET_COMBOBOX_SELECT

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to an integer that specifies the zero-based index of the combobox list element to be displayed. If the specified element is outside the range of existing elements, the selection remains unchanged.

## SET_DRAW_VIEW

This keyword applies to widgets created with the WIDGET_DRAW function.

A scrollable draw widget provides a large graphics area which is viewed through a smaller viewport. This keyword allows changing the current position of the viewport. The desired position is specified as a 2-element integer array giving the X and Y position in units specified by the UNITS keyword (pixels are the default) relative to the lower left corner of the graphics area. For example, to position the viewport to the lower left corner of the image:

```
WIDGET_CONTROL, widget, SET_DRAW_VIEW=[0, 0]
```

## SET_DROPLIST_SELECT

This keyword applies to widgets created with the WIDGET_DROPLIST function.

Set this keyword to an integer that specifies the droplist element to be current (i.e., the element that is displayed on the droplist button). Positions start at zero. If the specified element is outside the possible range, no new selection is set.

## SET_LIST_SELECT

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to an integer scalar or vector that specifies the list element or elements to be highlighted. The previous selection (if there is a selection) is cleared. Positions start at zero. If the specified element is outside the possible range, no new selection in set. Note that the MULTIPLE keyword to WIDGET_LIST must have been set in more than a single list element is specified.

If the selected position is not currently on the screen, the list widget automatically move the current scrolling viewport to make it visible. The resulting topmost visible element is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the SET_LIST_TOP keyword (described below) to explicitly set the viewport.

## SET_LIST_TOP

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to an integer that specifies the element of the list widget to the positioned at the top of the scrolling list. If the specified element is outside the range of list elements, nothing happens.

## SET_SLIDER_MAX

This keyword applies to widgets created with the WIDGET_SLIDER function.

Set this keyword to a new maximum value for the specified slider widget.

**Note**

This keyword does not apply to floating-point sliders created with the CW_FSLIDER function.

## SET_SLIDER_MIN

This keyword applies to widgets created with the WIDGET_SLIDER function.

Set this keyword to a new minimum value for the specified slider widget.

**Note**

This keyword does not apply to floating-point sliders created with the CW_FSLIDER function.

## SET_TAB_CURRENT

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword equal to the zero-based index of the tab to be set as the current (visible) tab. If the index value is invalid, the value is quietly ignored.

## SET_TAB_MULTILINE

This keyword applies to widgets created with the WIDGET_TAB function.

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and UNIX systems.

### Windows

Set this keyword to cause tabs to be organized in a multi-line display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If MULTILINE=0 and LOCATION=0 or 1, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If LOCATION=1 or 2, a multiline display is always used if the tabs exceed the height of the largest child base widget.

**Note**

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) may be truncated even if the MULTILINE keyword is set.

**UNIX**

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

**Note**

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. (Tab text may be truncated if the text of a single tab exceeds the space available, however.) This means that if MULTILINE is set to any value other than one, some tabs may not be displayed.

## SET_TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

- In standard selection mode, specify a four-element array, of the form [ *left, top, right, bottom* ] specifying the of cells to act upon.
- In disjoint selection mode, specify a 2 x *n* element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). The value -1 is used to refer to the title row or title column.

See "USE_TABLE_SELECT" on page 2206 for details on the selection modes.

**Note**

To remove a table selection programmatically, set this keyword to either `[-1, -1, -1, -1]` (in standard selection mode) or `[[-1, -1]]` (in disjoint selection mode).

If the selected position is not currently on the screen, the table widget automatically moves the current scrolling viewport to make a portion of it visible. The resulting top-left visible cell is toolkit specific. If you wish to ensure a certain element is at the top of the list, use the SET_TABLE_VIEW keyword to explicitly set the viewport.

## SET_TABLE_VIEW

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to a two-element array of zero-based cell indices that specifies the cell of the table widget to the positioned at the top-left of the widget. If the specified cell is outside the range of valid cells, nothing happens.

## SET_TEXT_SELECT

This keyword applies to widgets created with the WIDGET_TABLE and WIDGET_TEXT functions.

Use this keyword to clear any current selection in the specified table cell or text widget, and either set a new selection, or simply set the text insertion point. To set a selection, specify a two-element integer array containing the starting position and the length of the selection. For example, to set a selection covering characters 3 though 23:

```
WIDGET_CONTROL, widgetID, SET_TEXT_SELECT=[3, 20]
```

To move the text insertion point without setting a selection, omit the second element, or set it to zero.

## SET_TEXT_TOP_LINE

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to the zero-based line number of the line to be positioned on the topmost visible line in the text widget's viewport. No horizontal scrolling is performed. Note that this is a line number, not a character offset.

## SET_TREE_BITMAP

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget.

Set this keyword equal to zero to revert to the appropriate default system bitmap.

## SET_TREE_EXPANDED

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword equal to a nonzero value to expand the specified tree widget folder. Set this keyword equal to zero to collapse the specified tree widget folder.

## SET_TREE_SELECT

This keyword applies to widgets created with the WIDGET_TREE function.

This keyword has two modes of operation, depending on the widget ID passed to WIDGET_CONTROL:

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget):
  - If the tree widget is in multiple-selection mode and SET_TREE_SELECT is set to an array of widget IDs corresponding to tree widgets that are nodes in the tree, those nodes are selected.
  - If the tree widget is *not* in multiple-selection mode and SET_TREE_SELECT is set to a single widget ID corresponding to a tree widget that is a node in the tree, that node is selected.
  - If the keyword is set to zero, all selections in the tree widget are cleared.
- If the specified widget ID is a tree widget that is a node in a tree:
  - If the keyword is set to a nonzero value, the specified node is selected.
  - If the keyword is set to zero, the specified node is deselected.

**Note**

If the tree widget is in multiple-selection mode, the selection changes made to the tree widget via this keyword are additive — that is, the current selections are retained and any additional nodes specified by SET_TREE_SELECT are also selected.

## SET_TREE_VISIBLE

This keyword applies to widgets created with the WIDGET_TREE function and whose parent widget was also created using the WIDGET_TREE function (that is, tree widgets that are nodes of another tree).

Set this keyword to make the specified tree node *visible* to the user. Setting this keyword has two possible effects:

1. If the specified node is inside a collapsed folder, the folder and all folders above it are expanded to reveal the node.
2. If the specified node is in a portion of the tree that is not currently visible because the tree has scrolled within the parent base widget, the tree view scrolls so that the selected node is at the top of the base widget.

**Note**

Use of this keyword does not affect the tree widget selection state.

## SET_UNAME

This keyword applies to all widgets.

Set this keyword to a string that can be used to identify the widget. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID. You can set the name at creation time, using the UNAME keyword with the creation function.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## SET_UVALUE

This keyword applies to all widgets.

Each widget can contain a user-set value. This value is not used by IDL in any way, and exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value.

To improve the efficiency of the data transfer, consider using the NO_COPY keyword with SET_UVALUE.

## SET_VALUE

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, WIDGET_LABEL, WIDGET_LIST, WIDGET_SLIDER, WIDGET_TABLE, and WIDGET_TEXT functions.

Sets the value of the specified widget. The meaning of the value differs between widget types:

- Button: The label to be used for the button. This value can be either a scalar string, or a 2D byte array containing a bitmap.
- Combobox: The contents of the combobox widget (string or string array).
- Droplist: The contents of the droplist widget (string or string array).
- Label: The text to be displayed by the label widget.
- List: The contents of the list widget (string or string array).
- Property Sheet: Associates one or more component objects with a property sheet. Any existing associations are lost and the property sheet is reloaded with the new list of properties. Use the SET_VALUE keyword to WIDGET_CONTROL. Use the return value of OBJ_NEW() to clear out a property sheet.
- Slider: The current position of the slider (integer).
- Table: Normally, the data for the whole table is changed to the specified data, which must be of the form of a two dimensional array or a vector of structures. In this form, the table is resized to fit the given data (unless the TABLE_XSIZE or TABLE_YSIZE keywords are given).

  If the USE_TABLE_SELECT keyword is set, the value given is treated as a subset of the whole data, and only the given range of cells are updated. Used in this form, the type of data stored in the table cannot be changed. The data passed in is converted, as appropriate, to the type of the selected cells. If less data is passed in than fits in the current selection, the cells outside the range of data (but inside the selection) are left unchanged. If more data is passed in than fits in the current selection, the extra data is ignored.

  - If the table is in standard selection mode, the data should be a two-dimensional array of values for a single-type table, or a vector of structures for a table that contains structure data.
  - If the table is in disjoint selection mode, the data should be a one-dimensional array of values for a single-type table, or a single structure with each field corresponding to a cell for a table that contains structure data.

  If the USE_TEXT_SELECT keyword is present, the value must be a string, which replaces the currently-selected text in the currently-selected cell.
- Text: The text to be displayed. If the APPEND keyword is also specified, the text is appended to the current contents instead of instead of completely replacing it (string or string array). If the USE_TEXT_SELECT keyword is

specified, the new string replaces only the currently-selected text in the text widget.

- Widget types not listed above do not allow the setting of a value. Attempting to set the value of such a widget causes an error.

The value of a widget can also be set with the VALUE keyword to the routine that created it.

## SHOW

This keyword applies to all widgets.

Controls the visibility of a widget hierarchy. If set to zero, the hierarchy containing *Widget_ID* is pushed behind any other windows on the screen. If nonzero, the hierarchy is pulled in front.

## TABLE_BLANK

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to a nonzero value to cause the specified cells to be blank. Set this keyword equal to zero to cause the specified cells to display values as usual.

**Note**

Hiding cell contents using this keyword is a *display-only operation*. The cell contents are not actually removed from the table, they are simply hidden from view. Any operation that evaluates or changes the value of a cell will operate in the same way on a cell whose contents are hidden as it will on a cell whose contents are visible.

If the USE_TABLE_SELECT keyword is set equal to one, the currently selected cells are blanked or restored. If USE_TABLE_SELECT is set equal to an array, the specified cells are blanked or restored. If USE_TABLE_SELECT is not set, the entire table is hidden or displayed.

## TABLE_DISJOINT_SELECTION

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to enable the ability to select multiple rectangular regions of cells.

## TABLE_XSIZE

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to the number of data columns in the table widget. Note that if the table widget was created with row titles enabled (that is, if the NO_HEADERS keyword to WIDGET_TABLE was *not* set), the table will contain one column more than the number specified by TABLE_XSIZE.

If the table is made smaller as a result of the application of the TABLE_XSIZE keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new columns is set according to the following rules:

1. If the table was not created with either the ROW_MAJOR or COLUMN_MAJOR keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.
2. If the SET_VALUE keyword is given, the types of all columns are set according to the new structure.
3. If the table was created with the ROW_MAJOR keyword set, and the SET_VALUE keyword is not specified, the cells in the new columns inherit their type from the cells to their left.
4. ²If the table was created with the COLUMN_MAJOR keyword set, and the SET_VALUE keyword is not specified, any new columns default to type INT.

## TABLE_YSIZE

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword equal to the number of data rows in the table widget. Note that if the table widget was created with column titles enabled (that is, if the NO_HEADERS keyword to WIDGET_TABLE was *not* set), the table will contain one row more than the number specified by TABLE_YSIZE.

If the table is made smaller as a result of the application of the TABLE_YSIZE keyword, the data outside the new range persists, but the number of columns and/or rows changes as expected. If the table is made larger, the data type of the cells in the new rows is set according to the following rules:

1. If the table was not created with either the ROW_MAJOR or COLUMN_MAJOR keywords set (if the table is an array rather than a vector of structures), the new cells have the same type as all the original cells.
2. If the SET_VALUE keyword is given, the types of all rows are set according to the new structure.

3. If the table was created with the COLUMN_MAJOR keyword set, and the SET_VALUE keyword is not specified, the cells in the new rows inherit their type from the cells above.
4. If the table was created with the ROW_MAJOR keyword set, and the SET_VALUE keyword is not specified, any new rows default to type INT.

## TIMER

This keyword applies to all widgets.

If this keyword is present, a WIDGET_TIMER event is generated. Set this keyword to a floating-point value that represents the number of seconds before the timer event arrives. Note that this event is identical to any other widget event except that it contains only the 3 standard event tags. These event structures are defined as:

```
{ WIDGET_TIMER, ID:0L, TOP:0L, HANDLER:0L }
```

It is left to the caller to tell the difference between standard widget events and timer events. The standard way to do this is to use a widget that doesn't normally generate events (e.g., a base or label). Alternately, the TAG_NAMES function can be called with the STRUCTURE_NAME keyword to differentiate a WIDGET_TIMER event from other types of events. For example:

```
IF TAG_NAMES(event, /STRUCTURE_NAME) EQ $
   'WIDGET_TIMER' THEN ...
```

Using the TIMER keyword is more efficient than the background task functionality found in the XMANAGER procedure because it doesn't "poll" like the original background task code. RSI will eventually eliminate the background task functionality from XMANAGER. We encourage all users to modify their code to use the TIMER keyword instead.

## TLB_GET_OFFSET

This keyword applies to all widgets.

Set this keyword to a named variable in which the offset of the top-level base of the specified widget is returned, in units specified by the UNITS keyword (pixels are the default). The offset is measured in device coordinates relative to the upper-left corner of the screen.

## TLB_GET_SIZE

This keyword applies to all widgets.

Set this keyword to a named variable in which the size of the top-level base of the specified widget is returned, in units specified by the UNITS keyword (pixels are the

default). The size is returned as a two-element vector that contains the horizontal and vertical size of the base in device coordinates.

## TLB_ICONIFY_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to make the top-level base return an event when the base is iconified or restored by the user.

## TLB_KILL_REQUEST_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Use this keyword to set or clear kill request events for the specified top-level base. For more information on these events see "TLB_KILL_REQUEST_EVENTS" on page 2144.

## TLB_MOVE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to make the top-level base return an event when the base is moved by the user. Note that if TLB_SIZE_EVENTS are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

## TLB_SET_TITLE

This keyword applies to all widgets.

Set this keyword to a scalar string to change the title of the specified top-level base after it has been created.

## TLB_SET_XOFFSET

This keyword applies to all widgets.

Use this keyword to set the horizontal position of the top level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

## TLB_SET_YOFFSET

This keyword applies to all widgets.

Use this keyword to set the vertical position of the top-level base of the specified widget. The offset is measured from the upper-left corner of the screen to the upper-left corner of the base, in units specified by the UNITS keyword (pixels are the default).

## TLB_SIZE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to make the top-level base return an event when the base is resized by the user. Note that if TLB_MOVE_EVENTS are also enabled, a user resize operation that causes the top left corner of the base widget to move will generate both a move event and a resize event.

## TOOLTIP

This keyword applies to widgets created with the WIDGET_BUTTON and WIDGET_DRAW functions.

Set this keyword to a string that will be displayed when the cursor hovers over the specified widget. For UNIX platforms, this string must be non-zero in length, which means that a tooltip can be modified but not be removed on UNIX versions of IDL.

**Note**

Tooltips cannot be created for menu sub-items. The topmost button on a menu can, however, have a tooltip.

**Note**

If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

## TRACKING_EVENTS

This keyword applies to all widgets.

Set this keyword to a non-zero value to enable tracking events for the widget specified by *Widget_ID*. Set the keyword to 0 to disable tracking events for the specified widget. For a description of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNITS

This keyword applies to all widgets.

Use this keyword to specify the unit of measurement used for most widget sizing operations. Set UNITS equal to 0 to specify that all measurements are in pixels (this is the default), to 1 to specify that all measurements are in inches, or to 2 to specify that all measurements are in centimeters.

**Note**

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to WIDGET_LIST, WIDGET_TABLE, or WIDGET_TEXT functions.

## UPDATE

This keyword applies to all widgets.

Use this keyword to enable (if set to 1) or disable (if set to 0) screen updates for the widget hierarchy to which the specified widget belongs. This keyword is useful for preventing unwanted intermediate screen updates when changing the values of many widgets at once or when adding several widgets to a previously-realized widget hierarchy. When first realized, widget hierarchies are set to update.

**Note**

Do not attempt to resize a widget on the Windows platform while UPDATE is turned off. Doing so may prevent IDL from updating the screen properly when UPDATE is turned back on.

## USE_TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to modify the behavior of the ALIGNMENT, COLUMN_WIDTHS, DELETE_COLUMNS, DELETE_ROWS, FORMAT, GET_VALUE, INSERT_COLUMNS, INSERT_ROWS, ROW_HEIGHTS, SET_VALUE, and TABLE_BLANK keywords. If USE_TABLE_SELECT is set, these other keywords only apply to the currently-selected cells. Normally, these keywords apply to the entire contents of a table widget.

**Note**

If either the title row or the title column of the table is selected, this keyword only modifies the behavior of the ROW_HEIGHTS or COLUMN_WIDTHS keywords.

**Warning**

The Microsoft Windows platform does not support the ROW_HEIGHTS keyword. Selecting the title row of a table via USE_TABLE_SELECT has no effect.

### Selection Modes

The table widget supports two *selection modes*:

- In *standard selection mode*, only a single selection can be created at a given time. Creating a new selection causes the existing selection to disappear.
- In *disjoint selection mode*, multiple selections can be created at one time. Creating a new selection does not cause the existing selection(s) to disappear. A table can be created in disjoint selection mode using either the DISJOINT_SELECTION keyword to WIDGET_TABLE or the TABLE_DISJOINT_SELECTION keyword to WIDGET_CONTROL.

The keywords listed above to generate different output or expect different input based on the selection mode. See the description of each keyword for details. For more information on table selection modes, see "Selection Modes" in Chapter 27 of the *Building IDL Applications* manual

### Specifying Selections Programmatically

In many cases, your code will use a selection created by the user manually, with the mouse. You can also create selections programmatically, by setting USE_TABLE_SELECT equal to an array.

- In standard selection mode, specify a four-element array, of the form [ *left, top, right, bottom* ] specifying the of cells to act upon.
- In disjoint selection mode, specify a 2 x *n* element array of column/row pairs specifying the cells to act upon.

Specifications for cell locations are zero-based (that is, the first data column is column number zero). The value -1 is used to refer to the title row or title column.

**Note**

Setting USE_TABLE_SELECT equal to an array does *not* change the current table selection. Operations affect the specified cells without changing the current selection.

is equivalent to first calling WIDGET_CONTROL and setting the SET_TABLE_SELECT keyword equal to an array, and then calling WIDGET_CONTROL with USE_TABLE_SELECT set equal to one.

### Example

To change the column widths of the title column and the first five data columns of a table widget named `wTable`, leaving the widths of the other columns unchanged:

```
WIDGET_CONTROL, wTable, USE_TABLE_SELECT=[-1,0,4,0], $
    COLUMN_WIDTHS=50
```

For additional examples, see "Using Table Widgets" in Chapter 27 of the *Building IDL Applications* manual.

## USE_TEXT_SELECT

This keyword applies to widgets created with the WIDGET_TABLE and WIDGET_TEXT functions.

Set this keyword to modify the behavior of the GET_VALUE and SET_VALUE keywords. If USE_TEXT_SELECT is set, GET_VALUE and SET_VALUE apply only to the current text selection. Normally, these keywords apply to the entire contents of a text widget.

## X_BITMAP_EXTRA

This keyword applies to widgets created with the WIDGET_BUTTON function.

When the value of a button widget is a bitmap, the usual width is taken to be 8 times the number of columns in the source byte array. This keyword can be used to indicate the number of bits in the last byte of each row that should be ignored. The value can range between 0 and 7.

## XOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget's new horizontal offset, in units specified by the UNITS keyword (pixels are the default). Attempting to change the offset of a widget that is the child of a ROW or COLUMN base or a widget that is part of a menubar or pulldown menu causes an error.

## XSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget's new horizontal size.

- Text and List widgets: Size is specified in characters. The UNITS keyword is ignored.

- Table widgets: Size is specified in columns. The width of the row labels is automatically added to this value. The UNITS keyword is ignored.
- All other widgets: If the UNITS keyword is present, size is in the units specified. If the UNITS keyword is not present, the size is specified in pixels.

Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw widgets), this keyword adjusts the *viewport* size. Use the DRAW_XSIZE keyword to change the width of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

## YOFFSET

This keyword applies to all widgets.

Set this keyword to an integer value that specifies the widget's new vertical offset, in units specified by the UNITS keyword (pixels are the default). Attempting to change the offset of a widget that is the child of a ROW or COLUMN base or a widget that is part of a menubar or pulldown menu causes an error.

## YSIZE

This keyword applies to all widgets.

Set this keyword to an integer or floating-point value that represents the widget's new vertical size

- Text and List widgets: Size is specified in lines. The UNITS keyword is ignored.
- Table widgets: Size is specified in rows. The height of the column labels is automatically added to this value. The UNITS keyword is ignored.
- All other widgets: If the UNITS keyword is present, size is in the units specified. If the UNITS keyword is not present, the size is specified in pixels.

Note that [XY]SIZE sets client area and SCR_[XY]SIZE sets total area (title bar, borders, menu, client area). For scrollable widgets (e.g., scrolling bases and scrolling draw and table widgets), this keyword adjusts the *viewport* size. Use the DRAW_YSIZE keyword to change the height of the drawing area in scrolling draw widgets. Attempting to resize a widget that is part of a menubar or pulldown menu causes an error.

## Version History

Introduced: Pre 4.0

COMBOBOX_ADDITEM, COMBOBOX_DELETEITEM, COMBOBOX_INDEX, DRAW_KEYBOARD_EVENTS, SET_BUTTON, SET_COMBOBOX_SELECT, SET_TAB_CURRENT, SET_TAB_MULTILINE, SET_TREE_BITMAP, SET_TREE_EXPANDED, SET_TREE_SELECT, SET_TREE_VISIBLE, TABLE_BLANK, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP keywords added: 5.6

PUSHBUTTON_EVENTS keyword added: 6.0

Chapter 27, “Widget Application Techniques” in the *Building IDL Applications* manual.

# WIDGET_DISPLAYCONTEXTMENU

The WIDGET_DISPLAYCONTEXTMENU procedure displays a *context-sensitive menu* (also known as a *pop-up* or *shortcut* menu). Context-sensitive menus appear when the user clicks the right mouse button over a widget for which a context menu is defined. Because the widget programmer must explicitly detect the right-mouse button click and call WIDGET_DISPLAYCONTEXTMENU to display the context menu, a widget can have any number of associated context menus, which can be displayed under different circumstances.

Context menus are created by placing one or more button widgets on a base widget constructed with the CONTEXT_MENU keyword set. The context menu's base widget must have as its parent a base, draw, list, or text widget; in the case of all but draw widgets, the parent widget must be configured to generate context menu events via the CONTEXT_EVENTS keyword. Draw widgets that support context menus must have the BUTTON_EVENTS keyword set.

The widget application's event handler routine must detect the presence of a context menu event (base, list, and text widgets) or the right mouse-button event (draw and property sheet widgets) and call WIDGET_DISPLAYCONTEXTMENU to display the context menu. Events generated when the user clicks on the context menu's buttons are handled in the normal way. If the user clicks outside the context menu, it is dismissed and no event is generated.

## Syntax

WIDGET_DISPLAYCONTEXTMENU, *Parent, X, Y, ContextBase_ID*

## Arguments

### Parent

The widget ID of the parent widget of the context menu widget.

**Note**

The parent widget must be either a base, list, or text widget with the CONTEXT_EVENTS keyword set or a draw widget with the BUTTON_EVENTS keyword set. In most cases the parent widget can be identified via the ID field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.

### X

The x location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the x location of the user's right mouse-button click, as reported in the X field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.)

### Y

The y location, relative to the parent widget, at which the menu should be displayed. (In most cases this will be the y location of the user's right mouse-button click, as reported in the Y field of the WIDGET_CONTEXT or WIDGET_DRAW event structure.)

### ContextBase_ID

The widget ID of the context menu base widget that contains the context menu to be displayed. Use the CONTEXT_MENU keyword to WIDGET_BASE to create a context menu base.

**Note**

The context menu base must be a child of the widget specified by the *Parent* argument.

## Keywords

None.

## Examples

For examples using WIDGET_DISPLAYCONTEXTMENU, see "Context-Sensitive Menus" in Chapter 27 of the *Building IDL Applications* manual.

## Version History

Introduced: 5.5

# WIDGET_DRAW

The WIDGET_DRAW function is used to create draw widgets. Draw widgets are rectangular areas that IDL treats as standard graphics windows. Draw widgets can use either IDL Direct graphics or IDL Object graphics, depending on the value of the GRAPHICS_LEVEL keyword. Any graphical output that can be produced by IDL can be directed to a draw widget. Draw widgets can have optional scroll bars to allow viewing a larger graphics area than could otherwise be displayed in the widget's visible area.

The returned value of this function is the widget ID of the newly-created draw widget.

**Note**

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD( ) may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly.

For a more detailed discussion of the draw widget, along with examples, see "Using Draw Widgets" in Chapter 27 of the *Building IDL Applications* manual.

## Syntax

*Result* = WIDGET_DRAW(*Parent* [, /APP_SCROLL] [, /BUTTON_EVENTS] [, /COLOR_MODEL] [, COLORS=*integer*] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, /EXPOSE_EVENTS] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GRAPHICS_LEVEL=2] [, GROUP_LEADER=*widget_id*] [, KEYBOARD_EVENTS={1 | 2}] [, KILL_NOTIFY=*string*] [, /MOTION_EVENTS] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, RENDERER={0 | 1}] [, RESOURCE_NAME=*string*] [, RETAIN={0 | 1 | 2}] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SCROLL] [, /SENSITIVE] [, TOOLTIP=*string*] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, /VIEWPORT_EVENTS] [, XOFFSET=*value*] [, XSIZE=*value*] [, X_SCROLL_SIZE=*width*] [, YOFFSET=*value*] [, YSIZE=*value*] [, Y_SCROLL_SIZE=*height*] )

# Arguments

## Parent

The widget ID of the parent widget of the new draw widget.

# Keywords

## APP_SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

The drawable area of a draw widget created with the APP_SCROLL keyword is the same size as the viewable area (the *viewport*). This is useful for displaying very large images, because the memory used by a draw widget is directly related to the size of the drawable area. A draw widget created with the APP_SCROLL keyword also has the concept of a *virtual drawable area*, which is the size of the entire image. The fact that only a portion of the entire image is held in memory means that you must capture events generated when the user adjusts the scroll bars and display the correct portion of the image in your event-handling code.

**Note**

If the image you are displaying is relatively small or memory is not a concern, consider using the SCROLL keyword rather than APP_SCROLL. With SCROLL, the drawable area is the size of the entire image; this allows IDL to display the appropriate portions of the image automatically when the user adjusts the scroll bars. See "SCROLL" on page 2220 and "Scrolling Draw Widgets" in Chapter 27 of the *Building IDL Applications* manual for details.

Specify the size of the viewport using the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords, and the size of the virtual drawable area using the XSIZE and YSIZE keywords. If APP_SCROLL is set, the application generates viewport events even if the VIEWPORT_EVENTS keyword is not set.

If the drawable area uses Direct Graphics (that is, if GRAPHICS_LEVEL is *not* set equal to 2), system backing store is used by default and the viewport is automatically restored after it has been obscured. If you prefer to manually restore the viewport in an event-handling routine, set RETAIN=0 and EXPOSE_EVENTS=1; this allows you to redraw the virtual canvas when your application receives expose events.

If the drawable area uses Object Graphics (that is, if the GRAPHICS_LEVEL keyword is set equal to 2), the application will *not* automatically restore the viewport, and will generate expose events as if RETAIN=0 and EXPOSE_EVENTS=1 had been set.

## BUTTON_EVENTS

Set this keyword to make the draw widget generate events when the mouse buttons are pressed or released (and the mouse pointer is in the draw widget). Normally, draw widgets do not generate events.

You can use the event structure generated when the BUTTON_EVENTS keyword is set to emulate the functionality of the CONTEXT_EVENTS keyword to WIDGET_BASE, WIDGET_LIST, and WIDGET_TEXT. To determine whether the user clicked the right mouse button, use the test:

```
IF (event.release EQ 4)
```

where `event` holds the widget event structure.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 27 of the *Building IDL Applications* manual.

## COLOR_MODEL

Set this keyword equal to 1 (one) to cause the draw widget's associated IDLgrWindow object to use indexed color. If the COLOR_MODEL keyword is not set, or is set to a value other than one, the draw widget will use RGB color.

This keyword is only valid when the draw widget uses IDL Object Graphics. (The graphics type used by a draw widget is determined by setting the GRAPHICS_LEVEL keyword to WIDGET_DRAW.)

## COLORS

The maximum number of color table indices to be used. This parameter has effect *only* if it is supplied when the *first* IDL graphics window is created.

If COLORS is not specified when the first window is created, all or most of the available color indices are allocated, depending upon the window system in use.

To use monochrome windows on a color display, set COLORS equal to 2 when creating the first window. One color table is maintained for all IDL windows. A negative value for COLORS specifies that all but the given number of colors from the shared color table should be used.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EXPOSE_EVENTS

Set this keyword to make the draw widget generate event when the visibility of the draw widget changes. This may occur when the widget is hidden behind something else on the screen, brought to the foreground, or when the scroll bars are moved. Normally, draw widgets do not generate events.

If this keyword is set, expose events will be generated only when IDL is unable to restore the contents of the window itself. After the initial draw, expose events are not issued when GRAPHICS_LEVEL=2 and the software renderer is being used (RENDERER=1). In such cases, expose events are not issued because IDL can internally refresh the window itself. On platforms for which OpenGL support is not offered, the software renderer is always being used, and therefore, expose events are not issued after the initial draw.

**Note**

When using hardware rendering, you must explicitly disable backing store (by setting RETAIN=0) in order to generate expose events. Additional expose events may be generated if both EXPOSE_EVENTS and RETAIN=1 are turned on.

**Warning**

Large numbers of events may be generated when EXPOSE_EVENTS is specified. You may wish to compress the events (perhaps using a timer) and only act on a subset.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GRAPHICS_LEVEL

Set this keyword equal to 2 (two) to use IDL Object Graphics in the draw widget. If the GRAPHICS_LEVEL keyword is not set, or is set to a value other than two, the draw widget will use IDL Direct Graphics.

## GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KEYBOARD_EVENTS

Set this keyword equal to 1 (one) or 2 to make the draw widget generate an event when it has the keyboard focus and a key is pressed or released. (The method by which a widget receives the keyboard focus is dependent on the window manager in use.) The value of the key pressed is reported in either the `CH` or the `KEY` field of the event structure, depending on the type of key pressed. See “Widget Events Returned by Draw Widgets” on page 2224 for details.

- If this keyword is set equal to 1, the draw widget will generate an event when a “normal” key is pressed. “Normal” keys include all keys except function keys and the modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT. If a modifier key is pressed at the same time as a normal key, the value of the modifier key is reported in the `MODIFIERS` field of the event structure.
- If this keyword is set equal to 2, the draw widget will generate an event when *either* a normal key or a modifier key is pressed. Values for modifier keys are reported in the `KEY` field of the event structure, and the `MODIFIERS` field contains zero.

**Note**

Keyboard events are never generated for function keys.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## MOTION_EVENTS

Set this keyword to make the draw widget generate events when the mouse cursor moves across the widget. Normally, draw widgets do not generate events.

Draw widgets that return motion events can generate a large number of events that can result in poor performance on slower machines.

Note that it is possible to generate motion events with coordinates outside the draw widget. If you position the mouse cursor inside the draw widget, press the mouse button, and drag the cursor out of the draw widget, the X and Y fields of the widget event will specify coordinates outside the draw widget.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_DRAW or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE

keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See "Hardware vs. Software Rendering" in Chapter 34 of the *Using IDL* manual for details. Your choice of renderer may also affect the maximum size of a draw widget. See "IDLgrWindow" on page 3705 for details.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2139 for a complete discussion of this keyword.

## RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the draw widget. RETAIN=0 specifies no backing store. RETAIN=1 requests that the server or window system provide backing store. RETAIN=2 specifies that IDL provide backing store directly. See "Backing Store" on page 2228 for details on the

use of RETAIN with Direct Graphics. For more information on the use of RETAIN with Object Graphics, see “IDLgrWindow::Init” on page 3729.

## SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SCROLL

Set this keyword to create a scrollable draw widget with horizontal and vertical scrollbars that allow the user to view portions of the widget contents that are not currently on the screen.

Specify the size of the viewport using the X_SCROLL_SIZE and Y_SCROLL_SIZE keywords, and the size of the entire drawable area using the XSIZE and YSIZE keywords.

**Note**

While the viewport of a draw widget created with the SCROLL keyword may be smaller than the entire image, the drawable area itself is the same size as the image, and uses memory commensurately. If you want to display a portion of a very large image, consider using the APP_SCROLL keyword rather than SCROLL. The drawable area of a draw widget created with APP_SCROLL is the same size as the viewport. This saves memory when the displayed image is large, but requires extra work on the programmer’s part to handle viewport events and display the appropriate portion of the image. See “APP_SCROLL” on page 2214 and “Scrolling Draw Widgets” in Chapter 27 of the *Building IDL Applications* manual for details.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse

cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## TOOLTIP

Set this keyword to a string that will be displayed when the cursor hovers over the widget. For UNIX platforms, this string must be non-zero in length.

**Note**

If your application uses hardware rendering and a RETAIN setting of either zero or one, tooltips will cause draw widgets to generate expose events if the tooltip obscures the drawable area. This is true even if the tooltip is associated with another widget.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a draw widget is the IDL window number for use with Direct Graphics routines, such as WSET. For Object Graphics routines, it is the draw window object reference. This value cannot be set or modified by the user.

To obtain the window number for a newly-created draw widget, use the GET_VALUE keyword to WIDGET_CONTROL *after* the draw widget has been realized. Draw widgets do not have a window number assigned to them until they are realized. For example, to return the window number of a draw widget in the variable *win_num*, use the command:

```
WIDGET_CONTROL, my_drawwidget, GET_VALUE = win_num
```

where *my_drawwidget* is the widget ID of the desired draw widget.

When using Object Graphics for the widget draw, the following command returns an object reference to the draw window:

```
WIDGET_CONTROL, my_drawwidget, GET_VALUE = oWindow
```

where *oWindow* is a window object.

## VIEWPORT_EVENTS

Set this keyword to enable viewport motion events for draw widgets.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a “hint” to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

## X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the scrolling viewport independently of the actual width of the widget.

Use of the X_SCROLL_SIZE keyword implies SCROLL.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations. By default, draw widgets are 100 pixels wide by 100 pixels high.

## Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual height of the widget.

Use of the Y_SCROLL_SIZE keyword implies SCROLL.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of draw widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DRAW_BUTTON_EVENTS, DRAW_EXPOSE_EVENTS, DRAW_KEYBOARD_EVENTS, DRAW_MOTION_EVENTS, DRAW_VIEWPORT_EVENTS, DRAW_XSIZE, DRAW_YSIZE, GET_DRAW_VIEW, GET_VALUE, INPUT_FOCUS, SET_DRAW_VIEW, TOOLTIP.

## Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to draw widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: DRAW_BUTTON_EVENTS, DRAW_EXPOSE_EVENTS, DRAW_KEYBOARD_EVENTS, DRAW_MOTION_EVENTS, DRAW_VIEWPORT_EVENTS, TOOLTIP.

## Widget Events Returned by Draw Widgets

By default, draw widgets do not generate events. If the BUTTON_EVENTS keyword is set when the widget is created, pressing or releasing any mouse button while the mouse cursor is over the draw widget causes events to be generated. Specifying the MOTION_EVENTS keyword causes events to be generated *continuously* as the mouse cursor moves across the draw widget. Specifying the EXPOSE_EVENTS keyword causes events to be generated whenever the visibility of any portion of the draw window (or viewport) changes. Specifying the KEYBOARD_EVENTS keyword causes events to be generated when the draw widget has keyboard focus and a keyboard key is pressed.

The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_DRAW, ID:0L, TOP:0L, HANDLER:0L, TYPE: 0, X:0L, Y:0L,
   PRESS:0B, RELEASE:0B, CLICKS:0, MODIFIERS:0L, CH:0, KEY:0L }
```

**Note**

If you defined your own {WIDGET_DRAW} structures prior to the IDL 5.3 release before the structure was defined by an internal call, the MODIFIERS field will break the existing user code.

**Note**

If you defined your own {WIDGET_DRAW} structures prior to the IDL 5.6 release before the structure was defined by an internal call, the CH and KEY fields will break the existing user code.

ID, TOP, and HANDLER are the three standard fields found in every widget event. TYPE returns a value that describes the type of draw widget interaction that generated an event. The values for TYPE are shown in the table below.

| Value | Meaning |
|---|---|
| 0 | Button Press |
| 1 | Button Release |
| 2 | Motion |
| 3 | Viewport Moved (Scrollbars) |
| 4 | Visibility Changed (Exposed) |
| 5 | Key Press (ASCII character value reported in CH field) |
| 6 | Key Press (Non-ASCII key value reported in KEY field) |

*Table 98: Values for the TYPE field*

The X and Y fields give the device coordinates at which the event occurred, measured from the lower left corner of the drawing area.

For button and “viewport moved” events (that is, when the TYPE field contains 0, 1, or 3), PRESS and RELEASE are bitmasks that represent which of the left, center, or right mouse button was pressed:

| Bitmask | Mouse Button |
|---|---|
| 1 | Left |
| 2 | Middle |
| 4 | Right |

*Table 99: Bitmask for the PRESS and RELEASE Fields during Button Events*

For motion events, both PRESS and RELEASE are zero. For keyboard events, PRESS contains 1 (one) if the key is down and 0 (zero) if it is up; RELEASE contains 0 (zero) if the key is down and 1 (one) if it is up.

**Note**

IDL obtains information about which mouse button was pressed from the operating system, not from the mouse hardware itself. This means that if the operating system or some extension thereof remaps the mouse buttons, IDL may receive information that one button was pressed even if a different physical button was pressed. For example, if a user remaps the mouse buttons to reverse left and right, and then presses the right physical mouse button, the widget event structure will reflect a left mouse button press.

The CLICKS field is set to either 1 or 2 if the if the event is a button press event. If the time interval between two button-press events is less than the time interval for a double-click event for the platform, the CLICKS field returns 2. If the time interval between button-press events is greater than the time interval for a double-click event for the platform, the CLICKS field returns 1. This means that if you are writing a widget application that requires the user to double-click on a draw widget, you will need to handle two events. The CLICKS field will return a 1 on the first click and a 2 on the second click. If the event is not a button press event, the CLICKS field contains a 0.

The MODIFIERS field is valid for button press, button release, motion, and “normal” keyboard events. It is a bitmask which returns the current state of several keyboard modifier keys at the time the event was generated. If a bit is zero, the key is up. If the bit is set, the key is depressed.

**Note**

“Normal” keyboard events are generated when the KEYBOARD_EVENTS keyword is set equal to one. If KEYBOARD_EVENTS is set equal to two, the keypress event for a modifier key contains zero in the `MODIFIERS` field and the key value is reported in the `KEY` field; see below.

The value in the MODIFIERS field is generated by OR-ing the following values together if a key is depressed.

| Bitmask | Modifier Key |
|---|---|
| 1 | Shift |
| 2 | Control |
| 4 | Caps Lock |
| 8 | Alt (See Note following this table.) |

*Table 100: Bitmask for the MODIFIERS Field*

**Note**

Under UNIX, the Alt key is the currently mapped MOD1 key.

Keyboard events are generated with the value of the TYPE field equal to 5 or 6. If the event was generated by an ASCII keyboard character, the TYPE field will be set to 5 and the ASCII value of the key will be returned in the CH field. (Note that ASCII values can be converted to the string representing the character using the IDL STRING routine.) If the event was generated due to a non-ASCII keyboard character, the type of the event will be set to 6 and a numeric value representing the key will be returned in the KEY field. The following table lists the possible values of the KEY field.

Note that for the key values reported in the KEY field for the SHIFT, CONTROL, CAPS LOCK, and ALT keys are not the same as those reported in the MODIFIER field bit mask, since the KEY field is not a bitmask.

| Key Field Value | Keyboard Key |
|---|---|
| 1 | Shift |
| 2 | Control |
| 3 | Caps Lock |
| 4 | Alt |
| 5 | Left |

*Table 101: Modifier key values reported in the KEY field.*

| Key Field Value | Keyboard Key |
|---|---|
| 6 | Right |
| 7 | Up |
| 8 | Down |
| 9 | Page Up |
| 10 | Page Down |
| 11 | Home |
| 12 | End |

*Table 101: Modifier key values reported in the KEY field. (Continued)*

### Note on using CURSOR

Note that the CURSOR procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain the cursor position and button state information from a draw widget, examine the X, Y, PRESS, and RELEASE fields in the structures returned by the draw widget in response to cursor events.

## Backing Store

Draw widgets with scroll bars rely on backing store to repaint the visible area of the window as it is moved. Their performance is best on systems that provide backing store. However, if your system does not automatically provide backing store, you can make IDL supply it with the statement:

```
DEVICE, RETAIN=2
```

or by using the RETAIN keyword to WIDGET_DRAW.

**Note**

If you are using graphics acceleration, you may wish to turn off backing store entirely and enable expose events (via the EXPOSE_EVENTS keyword) and redraw the draw widget's contents manually. However, because the number of events generated may be quite high, you may wish to enable a timer as well and only redraw the draw widget periodically.

## Version History

Introduced: Pre 4.0

KEYBOARD_EVENTS, TOOLTIP keywords added: 5.6

# WIDGET_DROPLIST

The WIDGET_DROPLIST function creates “droplist” widgets. A droplist widget displays a text field and an arrow button. Selecting either the text field or the button reveals a list of options from which to choose. When the user selects a new option from the list, the list disappears and the text field displays the currently-selected option. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.

**Note**

The WIDGET_COMBOBOX function creates a similar widget that optionally allows users to edit the text displayed by the droplist. The combobox widget is intended to replace the droplist widget; RSI recommends that new code use WIDGET_COMBOBOX rather than WIDGET_DROPLIST.

## Syntax

*Result* = WIDGET_DROPLIST( *Parent* [, /DYNAMIC_RESIZE]
[, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*]
[, FRAME=*value*] [, FUNC_GET_VALUE=*string*]
[, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /NO_COPY]
[, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
[, /SENSITIVE] [, TITLE=*string*] [, /TRACKING_EVENTS] [, UNAME=*string*]
[, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*]
[, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*] )

## Return Value

The returned value of this function is the widget ID of the newly-created droplist widget.

## Arguments

### Parent

The widget ID of the parent widget for the new droplist widget.

# Keywords

## DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword does not take effect when used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3962 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a hint to the toolkit, and may be ignored in some instances.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_DROPLIST or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation

(GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2139 for a complete discussion of this keyword.

## SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## TITLE

Set this keyword to a string to be used as the title for the droplist widget.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a droplist widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The desired width of the droplist widget area, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size “around” the droplist button and, as such, is not particularly useful.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## YSIZE

The desired height of the widget, in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword does not control the size of the droplist button or of the dropped list. Instead, it controls the size “around” the droplist button and, as such, is not particularly useful.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of droplist widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DYNAMIC_RESIZE, GET_VALUE, SET_DROPLIST_SELECT, SET_VALUE.

## Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to droplist widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: DROPLIST_NUMBER, DROPLIST_SELECT, DYNAMIC_RESIZE.

## Widget Events Returned by Droplist Widgets

Pressing the mouse button while the mouse cursor is over an element of a droplist widget causes the widget to change the label on the droplist button and to generate an event. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{ WIDGET_DROPLIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L }
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This can be used to index the array of names originally used to set the widget's value.

**Note**

Platform-specific UI toolkits behave differently if a droplist widget has only a single element. On some platforms, selecting that element again does not generate an event. Events are always generated if the list contains multiple items.

## Version History

Introduced: 4.0

# WIDGET_EVENT

The WIDGET_EVENT function returns events for the widget hierarchy rooted at *Widget_ID*. Widgets communicate information by generating events. Events are generated when a button is pressed, a slider position is changed, and so forth.

**Note**

Widget applications should use the XMANAGER procedure in preference to calling WIDGET_EVENT directly. See "Widget Event Processing" in Chapter 26 of the *Building IDL Applications* manual.

## Event Processing

Events for a given widget are processed in the order that they are generated. The event processing performed by WIDGET_EVENT consists of the following steps, applied iteratively:

1. Wait for an event from one of the specified widgets to arrive.
2. Starting with the widget that generated the event, move up the widget hierarchy looking for a widget that has an associated event-handling procedure or function. Event-handling routines are associated with a widget via the EVENT_PRO and EVENT_FUNC keywords to the widget creation functions or the WIDGET_CONTROL procedure.
3. If an event-handling *procedure* is found, it is called with the event as its argument. The `HANDLER` field of the event is set to the widget ID of the widget associated with the handling procedure. When the procedure returns, WIDGET_EVENT returns to the first step above and starts searching for events. Hence, event-handling procedures are said to "swallow" events.
4. If an event-handling *function* is found, it is called with the event as its argument. The `HANDLER` field of the event is set to the widget ID of the widget associated with the handling function.

   When the function returns, its value is examined. If the value is not a structure, it is discarded and WIDGET_EVENT returns to the first step. This behavior allows event-handling functions to selectively act like event-handling procedures and "swallow" events.

   If the returned value is a structure, it is checked to ensure that it has the standard first three fields: `ID`, `TOP`, and `HANDLER`. If any of these fields is missing, IDL issues an error. Otherwise, the returned value replaces the event found in the first step and WIDGET_EVENT continues moving up the widget

hierarchy looking for another event handler routine, as described in step 2, above.

In situations where an event structure is returned, event functions are said to "rewrite" events. This ability to rewrite events is the basis of *compound widgets*, which combine several widgets to give the appearance of a single, more complicated widget. Compound widgets are an important widget programming concept. For more information, see "Compound Widgets" in Chapter 26 of the *Building IDL Applications* manual.

5. If an event reaches the top of a widget hierarchy without being swallowed by an event handler, it is returned as the value of WIDGET_EVENT.
6. If WIDGET_EVENT was called without an argument, and there are no widgets left on the screen that are being managed (as specified via the MANAGED keyword to the WIDGET_CONTROL procedure) and could generate events, WIDGET_EVENT ends the search and returns an *empty event* (a standard widget event structure with the top three fields set to zero).

**Note**

Do not interrupt the event loop by placing a STOP or EXIT command in the event-handler or other callback routine. The presence of either command will cause the widget routine to exit with an error.

# Syntax

*Result* = WIDGET_EVENT([*Widget_ID*]) [, BAD_ID=*variable*] [, /NOWAIT] [, /SAVE_HOURGLASS]

**UNIX Keywords:** [, /YIELD_TO_TTY]

# Return Value

A widget event is returned in a structure. The exact contents of this structure vary depending upon the type of widget involved. The first three elements of this structure, however, are always the same.

```
{ WIDGET, ID:0L, TOP:0L, HANDLER:0L, ... }
```

Any other elements vary from widget type to type. The three fixed elements are:

| Value | Meaning |
|---|---|
| ID | The widget ID of the widget that generated the event. |
| TOP | The widget ID of the top level base for the widget hierarchy containing `ID`. |
| HANDLER | When an event is passed as the argument to an event handling procedure or function, as discussed in the previous section, this field contains the identifier of the widget associated with the handler routine. When an event is returned from WIDGET_EVENT, this value is always zero to indicate that no handler routine was found. |

*Table 102: Common Event Structure Fields*

# Arguments

## Widget_ID

*Widget_ID* specifies the widget hierarchy for which events are desired. The first available event for the specified widget or any of its children is returned. If this argument is not specified, WIDGET_EVENT processes events for all existing widgets.

*Widget_ID* can also be an array of widget identifiers, in which case all of the specified widget hierarchies are searched.

**Note**

Attempting to obtain events for a widget hierarchy which is not producing events will hang IDL, unless the NOWAIT keyword is used.

# Keywords

## BAD_ID

If one of the values supplied via *Widget_ID* is not a valid widget identifier, this function normally issues an error and causes program execution to stop. However, if BAD_ID is present and specifies a named variable, the invalid ID is stored into the variable, and this routine quietly returns. If no error occurs, a zero is stored.

This keyword can be used to handle the situation in which IDL is waiting within WIDGET_EVENT when the user kills the widget hierarchy.

This keyword has meaning only if *Widget_ID* is explicitly specified.

### NOWAIT

When no events are currently available for the specified widget hierarchy, WIDGET_EVENT normally waits until one is available and then returns it. However, if NOWAIT is set and no events are present, it immediately returns. In this case, the ID field of the returned structure will be zero.

### SAVE_HOURGLASS

Set this keyword to prevent the hourglass cursor from being cleared by WIDGET_EVENT. This keyword can be of use if a program has to poll a widget periodically during a long computation.

### YIELD_TO_TTY (UNIX Only)

Unless the NOWAIT keyword is specified, WIDGET_EVENT does not return until the asked for event is available. If the user should enter a line of input from the keyboard, it cannot be processed until WIDGET_EVENT returns. If the YIELD_TO_TTY keyword is specified and the user enters a line of input, WIDGET_EVENT returns immediately. In this case, the ID field of the returned structure will be zero.

**Note**

This keyword is supported under UNIX only, and there are no plans to extend it to other operating systems. Do not use it if you intend to use non-UNIX systems.

## Version History

Introduced: Pre 4.0

XMANAGER

# WIDGET_INFO

The WIDGET_INFO function is used to obtain information about the widget subsystem and individual widgets. The specific area for which information is desired is selected by setting the appropriate keyword.

## Syntax

*Result* = WIDGET_INFO( [*Widget_ID*] )

**Keywords that apply to all widgets:** [, /ACTIVE] [, /CHILD] [, /EVENT_FUNC] [, /EVENT_PRO] [, FIND_BY_UNAME=*string*] [, /FONTNAME] [, /GEOMETRY] [, /KBRD_FOCUS_EVENTS] [, /MANAGED] [, /MAP] [, /NAME] [, /PARENT] [, /REALIZED] [, /SENSITIVE] [, /SIBLING] [, /SYSTEM_COLORS] [, /TRACKING_EVENTS] [, /TYPE] [, UNITS={0 | 1 | 2}] [, /UNAME] [, /UPDATE] [, /VALID_ID] [, /VERSION] [, /VISIBLE]

**Keywords that apply to widgets created with WIDGET_BASE:** [, /CONTEXT_EVENTS] [, /MODAL] [, /TLB_ICONIFY_EVENTS] [, /TLB_KILL_REQUEST_EVENTS] [, /TLB_MOVE_EVENTS] [, /TLB_SIZE_EVENTS]

**Keywords that apply to widgets created with WIDGET_BUTTON:** [, /BUTTON_SET] [, /DYNAMIC_RESIZE] [, /PUSHBUTTON_EVENTS] [, /TOOLTIP]

**Keywords that apply to widgets created with WIDGET_COMBOBOX:** [, /COMBOBOX_GETTEXT] [, /COMBOBOX_NUMBER] [, /DYNAMIC_RESIZE]

**Keywords that apply to widgets created with WIDGET_DRAW:** [, /DRAW_BUTTON_EVENTS] [, /DRAW_EXPOSE_EVENTS] [, DRAW_KEYBOARD_EVENTS={0 | 1 | 2}] [, /DRAW_MOTION_EVENTS] [, /DRAW_VIEWPORT_EVENTS] [, /TOOLTIP]

**Keywords that apply to widgets created with WIDGET_DROPLIST:** [, /DROPLIST_NUMBER] [, /DROPLIST_SELECT] [, /DYNAMIC_RESIZE]

**Keywords that apply to widgets created with WIDGET_LABEL:** [, /DYNAMIC_RESIZE]

**Keywords that apply to widgets created with WIDGET_LIST:** [, /CONTEXT_EVENTS] [, /LIST_MULTIPLE] [, /LIST_NUMBER] [, /LIST_NUM_VISIBLE] [, /LIST_SELECT] [, /LIST_TOP]

**Keywords that apply to widgets created with WIDGET_PROPERTYSHEET:**
[, COMPONENT=*objref*] [, /PROPERTY_VALID] [, /PROPERTY_VALUE]

**Keywords that apply to widgets created with WIDGET_SLIDER:**
[, /SLIDER_MIN_MAX]

**Keywords that apply to widgets created with WIDGET_TAB:**
[, /TAB_CURRENT] [, /TAB_MULTILINE] [, /TAB_NUMBER]

**Keywords that apply to widgets created with WIDGET_TABLE:**
[, /COLUMN_WIDTHS] [, /ROW_HEIGHTS{not supported in Windows}]
[, /TABLE_ALL_EVENTS] [, /TABLE_DISJOINT_SELECTION]
[, /TABLE_EDITABLE] [, /TABLE_EDIT_CELL] [, /TABLE_SELECT]
[, /TABLE_VIEW] [, /USE_TABLE_SELECT]

**Keywords that apply to widgets created with WIDGET_TEXT:**
[, /CONTEXT_EVENTS] [, /TEXT_ALL_EVENTS] [, /TEXT_EDITABLE]
[, /TEXT_NUMBER] [, TEXT_OFFSET_TO_XY=*integer*] [, /TEXT_SELECT]
[, /TEXT_TOP_LINE] [, TEXT_XY_TO_OFFSET=*[column, line]*]

**Keywords that apply to widgets created with WIDGET_TREE:**
[, /TREE_EXPANDED] [, /TREE_ROOT] [, /TREE_SELECT]

# Return Value

Returns the specified information for the given widget ID. If the SYSTEM_COLORS keyword is specified, a structure is returned. See "The WIDGET_SYSTEM_COLORS Structure" on page 2259 for details.

# Arguments

## Widget_ID

Usually this argument should be the widget ID of the widget for which information is desired. If the ACTIVE or VERSION keywords are specified, this argument is not required.

*Widget_ID* can also be an array of widget identifiers, in which case the result is an array with the same structure in which information on all the specified widgets is returned.

# Keywords

Not all keywords to WIDGET_INFO apply to all combinations of widgets. In the following list, descriptions of keywords that affect only certain types of widgets include a list of the widgets for which the keyword is useful.

## ACTIVE

This keyword applies to all widgets.

Set this keyword to return 1 if there is at least one realized, managed, top-level widget on the screen. Otherwise, 0 is returned.

## BUTTON_SET

This keyword applies to widgets created with the WIDGET_BUTTON function.

Set this keyword to return the “set” state of a widget button. If the button is currently set, 1 (one) is returned. If the button is currently not set, 0 (zero) is returned. This keyword is intended for use with exclusive, non-exclusive and checked menu buttons.

## CHILD

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first child of the widget specified by *Widget_ID*. If the widget has no children, 0 is returned.

## COLUMN_WIDTHS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return an array of long integers giving the width of each column in the table. If USE_TABLE_SELECT is set equal to one, only the column widths for columns that contain currently-selected cells are returned. If USE_TABLE_SELECT is set equal to an array, only the column widths for columns that contain specified cells are returned.

## COMBOBOX_GETTEXT

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to return the current text from the text box of the specified combobox widget. Note that when using an editable combobox, the text displayed in the text box may not be an item from the list of values in the combobox list. To obtain

the index of the selected item, inspect the INDEX field of the event structure returned by the combobox widget.

## COMBOBOX_NUMBER

This keyword applies to widgets created with the WIDGET_COMBOBOX function.

Set this keyword to return the number of elements currently contained in the list of the specified combobox widget.

## COMPONENT

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function. Set this keyword to an object reference to indicate which object to query. This is most useful when the property sheet references multiple objects. If this keyword is not specified, the first (possibly only) object is queried.

## CONTEXT_EVENTS

This keyword applies to widgets created with the WIDGET_BASE, WIDGET_LIST, or WIDGET_TEXT functions.

Set this keyword to return 1 (one) if the widget specified by *Widget_ID* is configured to generate context events (that is, the widget was created with the CONTEXT_EVENTS keyword). Otherwise, 0 (zero) is returned.

## DRAW_BUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the BUTTON_EVENTS attribute set. Otherwise, 0 is returned.

## DRAW_EXPOSE_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the EXPOSE_EVENTS attribute set. Otherwise, 0 is returned.

## DRAW_KEYBOARD_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return an integer specifying the type of keyboard events currently generated by the draw widget specified by *Widget_ID*. Possible values are:

- 0: No keyboard events are generated

- 1: Keyboard events are generated for “normal” keys (all keys except function keys and modifier keys: SHIFT, CONTROL, CAPS LOCK, and ALT).
- 2: Keyboard events are generated for “normal” keys and modifier keys.

**Note**

Keyboard events are never generated for function keys.

## DRAW_MOTION_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the MOTION_EVENTS attribute set. Otherwise, 0 is returned.

## DRAW_VIEWPORT_EVENTS

This keyword applies to widgets created with the WIDGET_DRAW function.

Set this keyword to return 1 if *Widget_ID* is a draw widget with the VIEWPORT_EVENTS attribute set. Otherwise, 0 is returned.

## DROPLIST_NUMBER

This keyword applies to widgets created with the WIDGET_DROPLIST function.

Set this keyword to return the number of elements currently contained in the specified droplist widget.

## DROPLIST_SELECT

This keyword applies to widgets created with the WIDGET_DROPLIST function.

Set this keyword to return the zero-based number of the currently-selected element (i.e., the currently-displayed element) in the specified droplist widget.

## DYNAMIC_RESIZE

This keyword applies to widgets created with the WIDGET_BUTTON, WIDGET_COMBOBOX, WIDGET_DROPLIST, and WIDGET_LABEL functions.

Set this keyword to return a True value (1) if the widget specified by *Widget_ID* is a button, droplist, or label widget that has had its DYNAMIC_RESIZE attribute set. Otherwise, False (0) is returned.

## EVENT_FUNC

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler function associated with *Widget_ID*. A null string is returned if no event handler function exists.

## EVENT_PRO

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the event handler procedure associated with *Widget_ID*. A null string is returned if no event handler procedure exists.

## FIND_BY_UNAME

This keyword applies to all widgets.

Set this keyword to a UNAME value that will be searched for in the widget hierarchy, and if a widget with the given UNAME is in the hierarchy, its ID is returned. The search starts in the hierarchy with the given widget ID and travels down, and this keyword returns the widget ID of the first widget that has the specified UNAME value.

If a widget is not found, 0 is returned.

## FONTNAME

This keyword applies to all widgets.

Set this keyword to return a string containing the name of the font being used by the specified widget. The returned name can then be used when creating other widgets or with the SET_FONT keyword to the DEVICE procedure. If fonts are not supported by the specified widget, an empty string is returned.

Note that you can use this keyword to retrieve the name of the *default* font used by one type of widget and use the same font in other contexts. For example, the following code retrieves the default font used for buttons and writes into the drawable area of a draw widget using the same font:

```
wBase = WIDGET_BASE(/ROW)
wButton = WIDGET_BUTTON(wBase, VALUE="Button")
wDraw = WIDGET_DRAW(wBase, XSIZE=200, YSIZE=100)
WIDGET_CONTROL, wBase, /REALIZE
strFont = WIDGET_INFO(wButton, /FONTNAME)
DEVICE, SET_FONT=strFont
```

```
WIDGET_CONTROL, wDraw, GET_VALUE=iWindow
WSET, iWindow
XYOUTS, 100, 50, 'Same Font as Button', FONT=0, /DEVICE, $
   ALIGNMENT=.5
```

This method allows you to synchronize the fonts in several widgets without knowing in advance which font is in use.

The format of the returned font name is platform dependent. See "About Device Fonts" on page 3962 for additional details.

## GEOMETRY

This keyword applies to all widgets.

**Note**

Some widgets have no geometry values of their own. For example, only the root node of a tree widget hierarchy has associated geometry values. Similarly, buttons created on a pop-up menu have no geometry. Widgets with no intrinsic geometry values will return a WIDGET_GEOMETRY structure containing all zeroes.

Set this keyword to return a WIDGET_GEOMETRY structure that describes the offset and size information for the widget specified by *Widget_ID*. This structure has the following definition:

```
{ WIDGET_GEOMETRY,
   XOFFSET:0.0,
   YOFFSET:0.0,
   XSIZE:0.0,
   YSIZE:0.0,
   SCR_XSIZE:0.0,
   SCR_YSIZE:0.0,
   DRAW_XSIZE:0.0,
   DRAW_YSIZE:0.0,
   MARGIN:0.0,
   XPAD:0.0,
   YPAD:0.0,
   SPACE:0.0 }
```

With the exception of MARGIN, all of the structure's fields correspond to the keywords of the same name to the various widget routines. MARGIN is the width of any frame added to the widget, in units specified by the UNITS keyword (pixels are the default). Therefore, the actual width of any widget is:

```
SCR_XSIZE + (2* MARGIN)
```

The actual height of any widget is:

```
SCR_YSIZE + (2 * MARGIN)
```

**Note**

Different window managers may use different *window dressing* (borders, margins, scrollbars, *etc*.). As a result, running a given segment of widget code on different platforms may yield different geometry.

## KBRD_FOCUS_EVENTS

This keyword applies to all widgets.

Set this keyword to return the keyboard focus events status of the widget specified by *Widget ID*. WIDGET_INFO returns 1 (one) if keyboard focus events are currently enabled for the widget, or 0 (zero) if they are not. Only base, table, and text widgets can generate keyboard focus events.

## LIST_MULTIPLE

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword equal to a named variable that will contain a non-zero value if the list widget supports multiple item selections. See the MULTIPLE keyword to WIDGET_LIST for more on multiple item selections.

## LIST_NUMBER

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the number of elements currently contained in the specified list widget.

## LIST_NUM_VISIBLE

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the number of elements that can be visible in the scrolling viewport of the specified list widget. Note that this value can be larger than the total number of elements actually in the list.

## LIST_SELECT

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the index or indices of the currently-selected (highlighted) element or elements in the specified list widget. Note that this offset is zero-based. If no element is currently selected, -1 is returned.

## LIST_TOP

This keyword applies to widgets created with the WIDGET_LIST function.

Set this keyword to return the zero-based offset of the topmost element currently visible in the specified list widget.

## MANAGED

This keyword applies to all widgets.

Set this keyword to return 1 if the specified widget is managed, or 0 otherwise. If no widget ID is specified in the call to WIDGET_INFO, the return value will be an array containing the widget IDs of all currently-managed widgets.

## MAP

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is mapped (visible), or False (0) otherwise. Note that when a base widget is unmapped, all of its children are unmapped. If WIDGET_INFO reports that a particular widget is unmapped, it may be because a parent in the widget hierarchy has been unmapped.

## MODAL

This keyword applies to widgets created with the WIDGET_BASE function and the MODAL keyword.

If this keyword is set, WIDGET_INFO will return True (1) if the base widget specified by *Widget_ID* is a modal base widget, or False (0) otherwise.

## NAME

This keyword applies to all widgets.

Set this keyword to return the widget type name of the widget specified by *Widget_ID*. The returned value will be one of the following strings: “BASE”, “BUTTON”, “COMBOBOX”, “DRAW”, “DROPLIST”, “LABEL”, “LIST”, “PROPERTYSHEET”, “SLIDER”, “TAB”, “TABLE”, “TEXT”, or “TREE”. Set the TYPE keyword to return the widget’s type code.

## PARENT

This keyword applies to all widgets.

Set this keyword to return the widget ID of the parent of the widget specified by *Widget_ID*. If the widget is a top-level base (i.e., it has no parent), 0 is returned.

## PROPERTY_VALID

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function. Set this keyword to a string to determine if the string identifies a property. Valid identifiers return 1 and invalid strings return 0. Comparisons are case insensitive.

Operations are performed on properties through unique identifiers. This operation is not required when processing a change event because the identifier returned in the event structure can be assumed to be correct.

## PROPERTY_VALUE

This keyword applies to widgets created with the WIDGET_PROPERTYSHEET function. Retrieves the value of an identified property from a property sheet and returns it as a temporary IDL variable. Set this keyword to a string that is a valid property identifier in order to return the value of the specified property. This value can then be used to set the actual value of the component's property—the property sheet does not automatically do this. When there are multiple components, use the COMPONENT keyword to indicate which component should be queried. The match is case insensitive. An invalid identifier throws an error.

This keyword is very often used in response to property sheet change events. This is because the property sheet does not change the underlying component; it only informs the widget program which of its own values have changed. The IDL programmer can use PROPERTY_VALUE to retrieve the user's desired value (as cached in the property sheet) and then apply it to the component. The following snippet of code handles property sheet change events:

```
PRO prop_event, e

; get the value of e.component's property identified by
; e.identifier
value = WIDGET_INFO( e.id, $
COMPONENT = e.component, $
PROPERTY_VALUE = e.identifier )

; set the component's property's value
e.component -> SetPropertyByIdentifier, $
   e.identifier, value

END
```

## PUSHBUTTON_EVENTS

This keyword applies to widgets created with the WIDGET_BUTTON function.

Set this keyword to return the pushbutton events status for the widget specified by *Widget_ID*. WIDGET_INFO returns 1 if pushbutton events are currently enabled for the widget, or 0 otherwise.

## REALIZED

This keyword applies to all widgets.

Set this keyword to return 1 if the widget specified by *Widget_ID* has been realized. If the widget has not been realized, 0 is returned.

## ROW_HEIGHTS

This keyword applies to widgets created with the WIDGET_TABLE function.

**Note**

This keyword is not supported under Microsoft Windows.

Set this keyword to return an array of long integers giving the height of each row in the table. If USE_TABLE_SELECT is set equal to one, only the row heights for rows that contain currently-selected cells are returned. If USE_TABLE_SELECT is set equal to an array, only the row heights for rows that contain specified cells are returned.

## SENSITIVE

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is sensitive (enabled), or False (0) otherwise. Note that when a base is made insensitive, all its children are made insensitive. If WIDGET_INFO reports that a particular widget is insensitive, it may be because a parent in the widget hierarchy has been made insensitive.

## SIBLING

This keyword applies to all widgets.

Set this keyword to return the widget ID of the first sibling of the widget specified by *Widget_ID*. If the widget is the last sibling in the chain, 0 is returned.

## SLIDER_MIN_MAX

This keyword applies to widgets created with the WIDGET_SLIDER function.

Set this keyword to return the current minimum and maximum values of the specified slider as a two-element integer array. Element 0 is the minimum value and element 1 is the maximum value.

## SYSTEM_COLORS

This keyword applies to all widgets.

Set this keyword and supply the widget ID of any widget to cause WIDGET_INFO to return an IDL structure that contains RGB values used for 25 IDL display elements.

For more detailed information on the WIDGET_SYSTEM_COLORS structure fields and their meaning see the "The WIDGET_SYSTEM_COLORS Structure" on page 2259.

## TAB_CURRENT

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword to return the zero-based index of the current tab in the tab widget.

## TAB_MULTILINE

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword to return the current setting of the multi-line mode for the tab widget.

## TAB_NUMBER

This keyword applies to widgets created with the WIDGET_TAB function.

Set this keyword to return the number of tabs contained in the tab widget.

## TABLE_ALL_EVENTS

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return 1 (one) if *Widget_ID* is a table widget with the ALL_EVENTS attribute set. Otherwise, 0 (zero) is returned.

## TABLE_DISJOINT_SELECTION

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return 1 (one) if the widget specified by *Widget_ID* has disjoint selection enabled. Otherwise, 0 (zero) is returned.

## TABLE_EDITABLE

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return 1 (one) if *Widget_ID* is a table widget that allows user editing of its contents. Otherwise, 0 (zero) is returned.

## TABLE_EDIT_CELL

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return a two-element integer array containing the row and column coordinates of the currently editable cell. If none of the cells in the table widget is currently editable, the array [-1, -1] is returned.

## TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return the currently-selected (highlighted) cells in the specified table widget.

- In standard selection mode, this keyword returns an array of the form [ *left*, *top*, *right*, *bottom* ] containing the zero-based indices of the columns and rows that define the selection.
- In disjoint selection mode (enabled by setting the DISJOINT_SELECTION keyword to WIDGET_TABLE), this keyword returns a 2 x *n* array of column/row pairs containing the zero-based indices the selected cells.

## TABLE_VIEW

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to return a two-element array of the form [*left*, *top*] containing the zero-based offsets of the top-left cell currently visible in the specified table widget.

## TEXT_ALL_EVENTS

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return 1 if *Widget_ID* is a text widget with the ALL_EVENTS attribute set. Otherwise, 0 is returned.

## TEXT_EDITABLE

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return 1 if *Widget_ID* is a text widget that allows user editing of its contents. Otherwise, 0 is returned.

## TEXT_NUMBER

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return the number of characters currently contained in the specified text widget, including end-of-line characters.

**Note**

On Windows platforms, Carriage Return/Line Feed pairs count as a single character.

## TEXT_OFFSET_TO_XY

This keyword applies to widgets created with the WIDGET_TEXT function.

Use this keyword to translate a text widget character offset into column and line form. The value of this keyword should be set to the character offset (an integer) to be translated. WIDGET_INFO returns a two-element integer array giving the column (element 0) and line (element 1) corresponding to the offset. If the offset specified is out of range, the array [-1,-1] is returned.

## TEXT_SELECT

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return the starting character offset and length (in characters) of the selected (highlighted) text in the specified text widget. WIDGET_INFO returns a two-element integer array containing the starting position of the highlighted text as an offset from character zero of the text in the widget (element 0), and length of the current selection (element 1).

## TEXT_TOP_LINE

This keyword applies to widgets created with the WIDGET_TEXT function.

Set this keyword to return the zero-based line number of the line currently at the top of a text widget's display viewport. Note that this value is different from the zero-based character offset of the characters in the line. The character offset can be calculated from the line offset via the TEXT_XY_TO_OFFSET keyword.

## TEXT_XY_TO_OFFSET

This keyword applies to widgets created with the WIDGET_TEXT function.

Use this keyword to translate a text widget position given in line and column form into a character offset. The value of this keyword should be set to a two-element integer array specifying the column (element 0) and line (element 1) position. WIDGET_INFO returns the character offset (as a longword integer) corresponding to the position. If the position specified is out of range, -1 is returned.

## TLB_ICONIFY_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return iconify events. Otherwise, 0 is returned.

## TLB_KILL_REQUEST_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return kill request events. Otherwise, 0 is returned.

## TLB_MOVE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return move events. Otherwise, 0 is returned.

## TLB_SIZE_EVENTS

This keyword applies to widgets created with the WIDGET_BASE function.

Set this keyword to return 1 if the top-level base widget specified by *Widget_ID* is set to return resize events. Otherwise, 0 is returned.

## TOOLTIP

This keyword applies to widgets created with the WIDGET_BUTTON and WIDGET_DRAW functions.

Set this keyword to have the WIDGET_INFO function return the text of the tooltip of the widget. If the widget does not have a tooltip, a null string will be returned.

## TRACKING_EVENTS

This keyword applies to all widgets.

Set this keyword to return the tracking events status for the widget specified by *Widget_ID*. WIDGET_INFO returns 1 if tracking events are currently enabled for the widget. Otherwise, 0 is returned.

## TREE_EXPANDED

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return 1 (one) if the specified tree widget node is a folder that is expanded, or 0 (zero) if the specified node is a folder that is collapsed.

**Note**

Only tree widget nodes created with the FOLDER keyword can be expanded or collapsed. This keyword will always return 0 (zero) if the specified tree widget node is not a folder.

## TREE_ROOT

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return the widget ID of the *root node* of the tree widget hierarchy of which *Widget ID* is a part. The root node is the tree widget whose parent is a base widget.

## TREE_SELECT

This keyword applies to widgets created with the WIDGET_TREE function.

Set this keyword to return information about the nodes selected in the specified tree widget. This keyword has two modes of operation, depending on the widget ID passed to WIDGET_INFO:

- If the specified widget ID is for the root node of the tree widget (the tree widget whose *Parent* is a base widget), this keyword returns either the widget ID of the selected node or (if multiple nodes are selected) an array of widget IDs of the selected nodes. If no nodes are selected, -1 is returned.
- If the specified widget ID is a tree widget that is a node in a tree, this keyword returns 1 (one) if the node is selected or 0 (zero) if it is not selected.

## TYPE

This keyword applies to all widgets.

Set this keyword to return the type code of the specified *Widget_ID*. Possible values are given the following table. Note that you can set the NAME keyword to return string names instead.

| Value | Type |
|---|---|
| 0 | Base |
| 1 | Button |
| 2 | Slider |
| 3 | Text |
| 4 | Draw |
| 5 | Label |
| 6 | List |
| 8 | Droplist |
| 9 | Table |
| 10 | Tab |
| 11 | Tree |
| 12 | Combobox |

*Table 103: Widget Type Codes*

## UNAME

This keyword applies to all widgets.

Set this keyword to have the WIDGET_INFO function return the user name of the widget.

## UNITS

This keyword applies to all widgets.

Use this keyword to specify the unit of measurement used when returning dimensions for most widget types. Set UNITS equal to 0 (zero) to specify that all measurements

are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

**Note**

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when retrieving the XSIZE or YSIZE of a WIDGET_LIST, WIDGET_TABLE, or WIDGET_TEXT functions.

## UPDATE

This keyword applies to all widgets.

Set this keyword to return 1 if the widget hierarchy that contains *Widget_ID* is set to display updates. Otherwise, 0 is returned. See "UPDATE" on page 2206.

## USE_TABLE_SELECT

This keyword applies to widgets created with the WIDGET_TABLE function.

Set this keyword to modify the behavior of the COLUMN_WIDTHS and ROW_HEIGHTS keywords. If USE_TABLE_SELECT is set, the COLUMN_WIDTHS and ROW_HEIGHTS keywords only apply to the currently-selected cells. Normally, these keywords apply to the entire contents of a table widget.

The USE_TABLE_SELECT keyword can also be specified as a four-element array, of the form [*left*, *top*, *right*, *bottom*], giving the group of cells to act on. In this usage, the value -1 is used to refer to the row or column titles.

## VALID_ID

This keyword applies to all widgets.

Set this keyword to return 1 if *Widget_ID* represents a currently-valid widget. Otherwise, 0 is returned.

## VERSION

This keyword applies to all widgets.

Set this keyword to return a structure that gives information about the widget implementation. This structure has the following definition:

```
{ WIDGET_VERSION, STYLE:'', TOOLKIT:'', RELEASE:'' }
```

`STYLE` is the style of widget toolkit used. `TOOLKIT` is the implementation of the toolkit. `RELEASE` is the version level of the toolkit. This field can be used to

distinguish between different releases of a given toolkit, such as Motif 1.0 and Motif 1.1.

### VISIBLE

This keyword applies to all widgets.

Set this keyword to return True (1) if the widget specified by *Widget_ID* is visible, or False (0) otherwise. A widget is visible if:

- it has been realized,
- it and all of its ancestors are mapped.

**Note**

The value returned by WIDGET_INFO when this keyword is set is not affected if the widget is minimized or obscured by another window. Widgets that are visible in the sense of this keyword may not be immediately apparent to a person viewing a particular display device.

## The WIDGET_SYSTEM_COLORS Structure

When the SYSTEM_COLORS keyword is specified in a call to WIDGET_INFO, IDL returns a WIDGET_SYSTEM_COLORS structure. This allows application developers to determine what colors are used in IDL application widgets, so they can design widgets for their application with the same look and feel as the supplied IDL widgets.

The WIDGET_SYSTEM_COLORS structure consists of 25 fields, each containing a three-element vector corresponding to the Red, Green, and Blue color values used for various widget elements. The vector elements are integers ranging between 0 and 255 if a color value is available (vector elements contain –1 if the color value is unavailable). The field names and meaning on the Windows and UNIX operating systems are shown in the following table.

| Field Names | Windows Platform | UNIX Platform |
|---|---|---|
| DARK_SHADOW_3D | Dark shadow color for 3D display elements. | N/A |

*Table 104: WIDGET_SYSTEM_COLORS Structure Fields*

| Field Names | Windows Platform | UNIX Platform |
|---|---|---|
| FACE_3D | Face color for 3D display elements and dialog boxes. | Base background color for all widgets. |
| LIGHT_EDGE_3D | Highlight color for 3D edges that face the light source. | Color of top and left edges of 3D widgets. |
| LIGHT_3D | Light color for 3D display elements. | Color of highlight rectangle around widgets with the keyboard focus. |
| SHADOW_3D | Color for 3D edges that face away from the light source. | Color of bottom and right edges of 3D widgets. |
| ACTIVE_BORDER | Active window's border color. | Push button background color when button is armed. |
| ACTIVE_CAPTION | Active window's caption color. | N/A |
| APP_WORKSPACE | Background color of MDI applications. | N/A |
| DESKTOP | Desktop color. | N/A |
| BUTTON_TEXT | Text color on push buttons. | Widget text color. |
| CAPTION_TEXT | Color of text in caption, size box, and scroll bar arrow box. | Widget text color. |
| GRAY_TEXT | Color of disabled text. | N/A |
| HIGHLIGHT | Color of item(s) selected in a widget. | Toggle button fill color. |

*Table 104: WIDGET_SYSTEM_COLORS Structure Fields (Continued)*

| Field Names | Windows Platform | UNIX Platform |
|---|---|---|
| HIGHLIGHT_TEXT | Color of text of item(s) selected in a widget. | N/A |
| INACTIVE_BORDER | Inactive window's border color. | N/A |
| INACTIVE_CAPTION | Inactive window's caption color. | N/A |
| INACTIVE_CAPTION_TEXT | Inactive window's caption text color. | N/A |
| TOOLTIP_BK | Background color for tooltip controls. | N/A |
| TOOLTIP_TEXT | Text color for tooltip controls. | N/A |
| MENU | Menu background color. | N/A |
| MENU_TEXT | Menu text color. | N/A |
| SCROLLBAR | Color of scroll bar "gray" area. | Color of scroll bar "gray" area. |
| WINDOW_BK | Window background color. | Base background color for all widgets. |
| WINDOW_FRAME | Window frame color. | Widget border color. |
| WINDOW_TEXT | Text color in windows. | Widget text color. |

*Table 104: WIDGET_SYSTEM_COLORS Structure Fields (Continued)*

## Version History

Introduced: Pre 4.0

BUTTON_SET, COMBOBOX_GETTEXT, COMBOBOX_NUMBER, FONTNAME, MAP, SENSITIVE, TAB_CURRENT, TAB_MULTILINE, TAB_NUMBER, TABLE_DISJOINT_SELECTION, TLB_ICONIFY_EVENTS, TLB_MOVE_EVENTS, TLB_SIZE_EVENTS, TOOLTIP, TREE_EXPANDED, TREE_ROOT, TREE_SELECT, and VISIBLE keywords added: 5.6

PUSHBUTTON_EVENTS keyword added: 6.0

## See Also

Chapter 26, “Creating Widget Applications” in the *Building IDL Applications* manual.

# WIDGET_LABEL

The WIDGET_LABEL function is used to create label widgets.

## Syntax

*Result* = WIDGET_LABEL( *Parent* [, /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT] [, /DYNAMIC_RESIZE] [, FONT=*string*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /SUNKEN_FRAME] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*] )

## Return Value

The returned value of this function is the widget ID of the newly-created label widget.

## Arguments

### Parent

The widget ID of the parent widget for the new label widget.

## Keywords

### ALIGN_CENTER

Set this keyword to center justify the label text.

### ALIGN_LEFT

Set this keyword to left justify the label text.

### ALIGN_RIGHT

Set this keyword to right justify the label text.

## DYNAMIC_RESIZE

Set this keyword to create a widget that resizes itself to fit its new value whenever its value is changed. Note that this keyword cannot be used with the SCR_XSIZE, SCR_YSIZE, XSIZE, or YSIZE keywords. If one of these keywords is also set, the widget will be sized as specified by the sizing keyword and will never resize itself dynamically.

## FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3962 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_LABEL or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “RESOURCE_NAME” on page 2139 for a complete discussion of this keyword.

## SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## SUNKEN_FRAME

Set this keyword to create a three dimensional, bevelled border around the label widget. The resulting frame gives the label a “sunken” appearance, similar to what is often seen in application status bars.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a widget label is a string containing the text for the label.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

### XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

### YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

### YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of label widgets. In addition to those keywords that affect all widgets, the following are particularly useful: DYNAMIC_RESIZE, GET_VALUE, SET_VALUE.

## Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO function return information that applies specifically to label widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: DYNAMIC_RESIZE.

## Widget Events Returned by Label Widgets

Label widgets do not return an event structure.

## Version History

Introduced: Pre 4.0

SUNKEN_FRAME keyword added: 5.6

## See Also

CW_FIELD, WIDGET_TEXT

# WIDGET_LIST

The WIDGET_LIST function is used to create list widgets. A list widget offers the user a list of text elements from which to choose. The user can select an item by pointing at it with the mouse cursor and pressing a button. This action generates an event containing the index of the selected item, which ranges from 0 to the number of elements in the list minus one.

The returned value of this function is the widget ID of the newly-created list widget.

## Syntax

*Result* = WIDGET_LIST( *Parent* [, /CONTEXT_EVENTS]
[, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*]
[, FRAME=*width*] [, FUNC_GET_VALUE=*string*]
[, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /MULTIPLE]
[, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
[, /SENSITIVE] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*]
[, YOFFSET=*value*] [, YSIZE=*value*] )

## Return Value

The returned value of this function is the widget ID of the newly-created list widget.

## Arguments

### Parent

The widget ID of the parent widget for the new list widget.

## Keywords

### CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID

to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 27 of the *Building IDL Applications* manual.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 3962 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a "hint" to the toolkit, and may be ignored in some instances.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## MULTIPLE

Set this keyword to allow the user to select more than one item from the list in a single operation. Multiple selections are handled using the platform’s native mechanism:

### Motif

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the mouse button when selecting items also selects a range. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

### Windows

Holding down the Shift key and clicking an item selects the range from the previously selected item to the new item. Holding down the Control key and clicking an item toggles that item between the selected and unselected state.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL

makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_LIST or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “RESOURCE_NAME” on page 2139 for a complete discussion of this keyword.

## SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

**Note**

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to WIDGET_LIST.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a list widget is a scalar string or array of strings that contains the text of the list items—one list item per array element. List widgets are sized based on the length (in characters) of the longest item specified in the array of values for the VALUE keyword.

Note that the value of a list widget can only be set. It cannot be retrieved using WIDGET_CONTROL.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The desired width of the widget, in characters. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

### YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

### YSIZE

The desired height of the widget, in number of list items visible. Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. Note that the final size of the widget may be adjusted to include space for scrollbars (which are not always visible), so your widget may be slightly larger than specified.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of list widgets. In addition to those keywords that affect all widgets, the following are particularly useful: CONTEXT_EVENTS, SET_LIST_SELECT, SET_LIST_TOP, SET_VALUE.

## Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to list widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: CONTEXT_EVENTS, LIST_MULTIPLE, LIST_NUMBER, LIST_NUM_VISIBLE, LIST_SELECT, LIST_TOP.

## Widget Events Returned by List Widgets

Pressing the mouse button while the mouse cursor is over an element of a list widget causes the widget to highlight the appearance of that element and to generate an event. The appearance of any previously selected element is restored to normal at the same time. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_LIST, ID:0L, TOP:0L, HANDLER:0L, INDEX:0L, CLICKS:0L}
```

The first three fields are the standard fields found in every widget event. INDEX returns the index of the selected item. This index can be used to subscript the array of names originally used to set the widget's value. The CLICKS field returns either 1 or 2, depending upon how the list item was selected. If the list item is double-clicked, CLICKS is set to 2.

**Note**

If you are writing a widget application that requires the user to double-click on a list widget, you will need to handle two events. The CLICKS field will return a 1 on the first click and a 2 on the second click.

### Context Menu Events

List widgets return the following event structure when the user clicks the right mouse button and the list widget was created with the CONTEXT_EVENTS keyword set:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the list widget.

## Version History

Introduced: Pre 4.0

CW_BGROUP, WIDGET_COMBOBOX, WIDGET_DROPLIST

# WIDGET_PROPERTYSHEET

The WIDGET_PROPERTYSHEET function creates a property sheet widget, which exposes the *properties* of an IDL object subclassed from the IDLitComponent class in a graphical interface. The property sheet widget must be a child of a base or tab widget, and it cannot be the parent of any other widget.

The property sheet widget exposes the properties of an IDL object that subclasses from the IDLitComponent class, which was designed for use by the IDL iTools system. As a result, all IDLit* objects subclass from IDLitComponent, so properties of object classes written for the IDL iTools system can be displayed in a property sheet. In addition, all IDLgr* objects subclass from IDLitComponent, which means that properties of standard IDL graphics objects can be displayed in a property sheet even if the rest of the iTools framework is not in use.

In order to be shown in a property sheet, object properties must be *registered* and *visible*. In addition, in order for property values shown in a property sheet to be editable by the user, the property must be *sensitive*. For information on registering properties, see "Registering Properties" in Chapter 4 of the *iTool Developer's Guide* manual. For information on making properties visible and sensitive, see "Property Attributes" in Chapter 4 of the *iTool Developer's Guide* manual.

## Syntax

*Result* = WIDGET_PROPERTYSHEET(*Parent* [, /ALIGN_BOTTOM
|, /ALIGN_CENTER |, /ALIGN_LEFT |, /ALIGN_RIGHT |, /ALIGN_TOP]
[, /CONTEXT_EVENTS] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*]
[, FONT=*string*] [, FUNC_GET_VALUE=*string*] [, KILL_NOTIFY=*string*]
[, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE]
[, /TRACKING_EVENTS] [, UNAME=*string*] [,UNITS={0 | 1 | 2}]
[, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*]
[, YOFFSET=*value*] [, YSIZE=*value*])

## Return Value

The returned value of this function is the widget ID of the newly-created property sheet widget.

# Arguments

## Parent

The widget ID of the parent for the new property sheet widget. *Parent* must be a base or tab widget.

# Keywords

## ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

## ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

## ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

## CONTEXT_EVENTS

Set this keyword to cause *context menu events* (or simply *context events*) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program’s event handler to display the context menu.

For more on detecting and handling context menu events, see “Context-Sensitive Menus” in Chapter 26 of the *Building IDL Applications* manual.

**Note**

With regard to /CONTEXT_EVENTS, the Motif and Windows version of the property sheet differ very slightly. In the Motif version, individually desensitized cells cannot generate context events, though their row label can.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” in Appendix I of the *IDL Reference Guide* manual for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

**Note**

A procedure specified via the CLEANUP keyword to XMANAGER will override a procedure specified for your application's top-level base with WIDGET_BASE, KILL_NOTIFY.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. During a set operation (using the UVALUE keyword to WIDGET_BASE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. During a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently

## SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

**Note**

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” in the *IDL Reference Guide* manual in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The user value to be assigned to the widget. Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

The user value for a widget can be accessed and modified at any time by using the GET_UVALUE and SET_UVALUE keywords to the WIDGET_CONTROL procedure.

## VALUE

Set this keyword to the object reference or array of object references to objects that subclass from the IDLitComponent class. Registered properties of the specified objects will be displayed in the property sheet.

If a single object reference is supplied, the property sheet will have a single column containing the object's properties. If an array of object references is supplied, the property sheet will have multiple columns.

**Note**

Due to limitations of the user interface controls that underlie the property sheet widget, a property sheet can display properties for at most 100 component objects.

**Note**

All object references must be to objects of the same type.

If no object references are supplied, the property sheet will initially be empty. Object references can be loaded into an existing property sheet using the SET_VALUE keyword to WIDGET_CONTROL.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a bulletin board base widget. Note that it is best to avoid using this style of widget layout.

## XSIZE

The desired width, in average character widths, for the widget's font, not including a possible vertical scrollbar and any frame thickness. If neither XSIZE nor SCR_XSIZE is specified, then the property sheet widget will use a default width. This default width is computed by adding the room needed for the property names to the width of a color cell.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a bulletin board base widget. Note that it is best to avoid using this style of widget layout.

## YSIZE

The desired height of the widget, in number of visible properties. The ultimate height of the property sheet in pixels will include the heights of the column header, the possible horizontal scrollbar, and any frame. If neither YSIZE nor SCR_YSIZE is specified, the property sheet will use a default height. This default is based on the number of rows: 10, or the number of visible properties, whichever is less.

# Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of property sheet widgets. In addition to those keywords that affect all widgets, the following keyword is particularly useful: REFRESH _PROPERTY.

# Keywords to WIDGET_INFO

Some keywords to WIDGET_INFO return information that applies specifically to property sheet widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: COMPONENT, PROPERTY_VALID, PROPERTY_VALUE.

# Widget Events Returned by Property Sheet Widgets

Several variations of the property sheet widget event structure depend upon the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned or which type of event was generated. Programs should always check the type field before referencing fields that are not present in all property sheet event structures. The different property sheet widget event structures are described below.

## Change Event (TYPE=0)

This event is generated whenever the user enters a new value for a property. It is also used to signal that a user-defined property needs to be changed. The following statement defines the event structure returned by the WIDGET_EVENT function:

```
{WIDGET_PROPSHEET_CHANGE, ID:0L, TOP:0L, HANDLER:0L, TYPE:0L,
   COMPONENT:OBJREF, IDENTIFIER:"", PROPTYPE:0L, SET_DEFINED: OL}
```

The COMPONENT field contains an object reference to the object associated with the property sheet. When multiple objects are associated with the property sheet, this field indicates which object is to change.

The IDENTIFIER field specifies the value of the property’s identifier attribute. This identifier is unique among all of the component’s properties.

The PROPTYPE field indicates the type of the property (integer, string, etc.). The integer values for these types are:

- 0 = USERDEF
- 1 = BOOLEAN
- 2 = INTEGER
- 3 = FLOAT
- 4 = STRING
- 5 = COLOR
- 6 = LINESTYLE
- 7 = SYMBOL
- 8 = THICKNESS
- 9 = ENUMLIST

The SET_DEFINED field indicates whether or not an undefined property is having its value set. In most circumstances, along with its new value, the property should have its UNDEFINED attribute set to zero. If a property is never marked as undefined, this field can be ignored.

## Select Event (TYPE=1)

The select event is generated whenever the current row or column in the property sheet changes. Navigation between cells is performed by clicking on a cell. When the property sheet is realized, no cell is selected.

The following statement defines the event structure returned by the WIDGET_EVENT function:

```
{WIDGET_PROPSHEET_SELECT, ID:0L, TOP:0L, HANDLER:0L, TYPE:0L,
   COMPONENT:OBJREF, IDENTIFIER:""}
```

The COMPONENT field is an object reference to the object associated with the property sheet.

The IDENTIFIER field specifies the value of the property’s identifier attribute. This identifier is unique among all properties of the component.

# Example

Enter the following program in the IDL Editor:

```
; ExSinglePropSheet
;
; Creates a base with a property sheet. Only the
; default properties are visible. The property sheet's
; event handler sets values and reveals selection
; changes.

PRO PropertyEvent, event

IF (event.type EQ 0) THEN BEGIN ; Value changed.

   ; Get the value of the property identified by
   ; event.identifier.
   value = WIDGET_INFO(event.id, COMPONENT = event.component, $
      PROPERTY_VALUE = event.identifier)

   ; Set the component's property value.
   event.component -> SetPropertyByIdentifier, event.identifier, $
      value

   PRINT, 'Changed: ', event.identifier, ': ', value

ENDIF ELSE BEGIN ; Selection changed.

   PRINT, 'Selected: ' + event.identifier

ENDELSE

END

PRO ExSinglePropSheet_event, event

prop = WIDGET_INFO(event.top, $
   FIND_BY_UNAME = 'PropSheet')
WIDGET_CONTROL, prop, XSIZE = event.x, YSIZE = event.y

END

PRO CleanupEvent, baseID

WIDGET_CONTROL, baseID, GET_UVALUE = oComp
OBJ_DESTROY, oComp

END
```

```
PRO ExSinglePropSheet

; Create and initialize the component.
oComp = OBJ_NEW('IDLitVisAxis')

; Create a base and property sheet.
base = WIDGET_BASE(/TLB_SIZE_EVENT, $
   TITLE = 'Single Property Sheet Example', $
   KILL_NOTIFY = 'CleanupEvent')
prop = WIDGET_PROPERTYSHEET(base, VALUE = oComp, $
   EVENT_PRO = 'PropertyEvent', UNAME = 'PropSheet')

; Activate the widgets.
WIDGET_CONTROL, base, SET_UVALUE = oComp, /REALIZE

XMANAGER, 'ExSinglePropSheet', base, /NO_BLOCK

END
```

Save this program as `ExSinglePropSheet.pro`, then compile and run the program. A property sheet entitled Single Property Sheet Example is displayed:

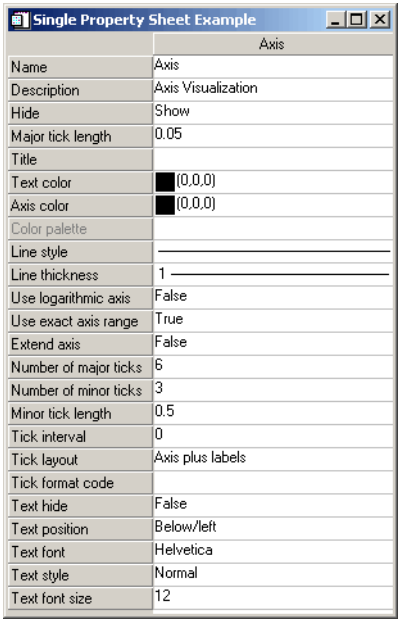

*Figure 30: Single Property Sheet Example*

For examples of the types of settings possible from the property sheet:

- Click the **Hide** setting box, click the drop-down button, and select `Hide` from the list.
- Click the **Major tick length** setting box, click the drop-down button, and move the slider to select a new value.
- Click the **Text color** setting box, click the drop-down button, and select a new color from the color selector.

## Version History

Introduced: 6.0

# WIDGET_SLIDER

The WIDGET_SLIDER function is used to create slider widgets. Slider widgets are used to indicate an integer value from a range of possible values. They consist of a rectangular region which represents the possible range of values. Inside this region is a sliding pointer that displays the current value. This pointer can be manipulated by the user via the mouse, or from within IDL via the WIDGET_CONTROL procedure.

To indicated floating-point values, see CW_FSLIDER.

## Syntax

*Result* = WIDGET_SLIDER( *Parent* [, /DRAG] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, MAXIMUM=*value*] [, MINIMUM=*value*] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, SCROLL=*units*] [, /SENSITIVE] [, /SUPPRESS_VALUE] [, /TRACKING_EVENTS] [, TITLE=*string*] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, /VERTICAL] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*] )

## Return Value

The returned value of this function is the widget ID of the newly-created slider widget.

## Arguments

### Parent

The widget ID of the parent for the new slider widget.

## Keywords

### DRAG

Set this keyword to cause events to be generated continuously while the slider is being dragged by the user. Normally, slider widgets generate position events only when the slider comes to rest at its final position and the mouse button is released.

**Note**

Under Microsoft Windows, this keyword has no effect. IDL sliders only generate events when the mouse button is released.

When a slider widget is set to return drag events, a large number of events can be generated. On slower machines, poor performance can result. Therefore, this option should only be used when detailed or truly interactive control is required.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3962 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this

technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string ( ' ' ).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## MAXIMUM

The maximum value of the range encompassed by the slider. If this keyword is not supplied, a default of 100 is used.

## MINIMUM

The minimum value of the range encompassed by the slider. If this keyword is not supplied, a default of 0 is used.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would

otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_SLIDER or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See “RESOURCE_NAME” on page 2139 for a complete discussion of this keyword.

## SCR_XSIZE

Set this keyword to the desired “screen” width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired “screen” height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SCROLL

Set the SCROLL keyword to an integer value specifying the number of integer units the scroll bar should move when the user clicks the left mouse button inside the slider area (Motif) or on the slider arrows (Windows), but not on the slider itself. The

default on both platforms is 0.1 x (MAXIMUM - MINIMUM), which is 10% of the slider range.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## SUPPRESS_VALUE

Set this keyword to inhibit the display of the current slider value.

Sliders work only with integer units. This keyword can be used to suppress the actual value of a slider so that a program can present the user with a slider that seems to work in other units (such as floating-point) or with a non-linear scale.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## TITLE

A string containing the title to be used for the slider widget.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget

hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget’s initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a widget slider is the current position of the slider.

## VERTICAL

Set this keyword to create a vertical slider. If this keyword is omitted, the slider is horizontal.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the

desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

**Note**

Setting XSIZE for a vertical slider (created with the VERTICAL keyword) does not change the visible width of the slider itself, but does change the amount of horizontal space occupied by the widget within its parent base.

### YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

### YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a "hint" to the toolkit and may be ignored in some situations.

**Note**

Setting YSIZE for a horizontal slider does not change the visible height of the slider itself, but does change the amount of vertical space occupied by the widget within its parent base.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of slider widgets. In addition to those keywords that affect all widgets, the following are particularly useful: GET_VALUE, SET_SLIDER_MAX, SET_SLIDER_MIN, SET_VALUE.

## Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO function return information that applies specifically to slider widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: SLIDER_MIN_MAX.

## Widget Events Returned by Slider Widgets

Slider widgets generate events when the mouse is used to change their value. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_SLIDER, ID:0L, TOP:0L, HANDLER:0L, VALUE:0L, DRAG:0}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. VALUE returns the new value of the slider. DRAG returns integer 1 if the slider event was generated as part of a drag operation, or zero if the event was generated when the user had finished positioning the slider. Note that the slider widget only generates events during the drag operation if the DRAG keyword is set. When the DRAG keyword is set, the DRAG field can be used to avoid computationally expensive operations until the user releases the slider.

## Known Implementation Problems

Under Motif 1.0, vertical sliders with a title organized in row bases get horizontally truncated and the slider doesn’t show (the title does). Use the XSIZE keyword to work around this.

## Version History

Introduced: Pre 4.0

## See Also

CW_FSLIDER

# WIDGET_TAB

The WIDGET_TAB function is used to create a tab widget. Tab widgets present a display area on which different pages (base widgets and their children) can be displayed by selecting the appropriate tab. The titles of the tabs are supplied as the values of the TITLE keyword for each of the tag widget's child base widgets.

For a more detailed discussion of the tab widget, along with examples, see "Using Tab Widgets" in Chapter 27 of the *Building IDL Applications* manual.

## Syntax

*Result* = WIDGET_TAB( *Parent* [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, LOCATION={0 | 1 | 2 | 3}] [, MULTILINE=0 | 1 (Windows) or *num* tabs per row (Motif)] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*] )

## Return Value

The returned value of this function is the widget ID of the newly-created tab widget.

## Arguments

### Parent

The widget ID of the parent for the new tab widget.

**Note**

Only base widgets can be the parent of a tab widget.

# Keywords

## ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

## ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

## ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this

technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). Note that the procedure specified is used only if you are not using the XMANAGER procedure to manage your widgets.

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

If you use the XMANAGER procedure to manage your widgets, the value of this keyword is overwritten. Use the CLEANUP keyword to XMANAGER to specify a procedure to be called when a managed widget dies.

## LOCATION

Set this keyword equal to an integer that specifies which edge of the tab widget will contain the tabs. The possible values are:

| Value | Description |
|---|---|
| 0 | The tabs are placed along the top of the widget, which is the default behavior. |
| 1 | The tabs are placed along the bottom of the widget. |

*Table 105: LOCATION Keyword Values*

| Value | Description |
|---|---|
| 2 | The tabs are placed along the left edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword. |
| 3 | The tabs are placed along the right edge of the widget. The text label for each tab is displayed vertically. On Windows platforms, setting the keyword to this value implies the MULTILINE keyword. |

*Table 105: LOCATION Keyword Values (Continued)*

## MULTILINE

This keyword controls how tabs appear on the tab widget when all of the tabs do not fit on the widget in a single row. This keyword behaves differently on Windows and Motif systems.

### Windows

Set this keyword to cause tabs to be organized in a multiline display when the width of the tabs exceeds the width of the largest child base widget. If possible, IDL will create tabs that display the full tab text.

If MULTILINE = 0 and LOCATION = 0 or 1, tabs that exceed the width of the largest child base widget are shown with scroll buttons, allowing the user to scroll through the tabs while the base widget stays immobile.

If LOCATION = 1 or 2, a multiline display is always used if the tabs exceed the height of the largest child base widget.

**Note**

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) may be truncated even if the MULTILINE keyword is set.

### Motif

Set this keyword equal to an integer that specifies the maximum number of tabs to display per row in the tab widget. If this keyword is not specified (or is explicitly set equal to zero) all tabs are placed in a single row.

**Note**

The width or height of the tab widget is based on the width or height of the largest base widget that is a child of the tab widget. The text of the tabs (the titles of the tab widget's child base widgets) is never truncated in order to make the tabs fit the space available. However, tab text may be truncated if the text of a single tab exceeds the space available. If MULTILINE is set to any value other than one, some tabs may not be displayed.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_TAB or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

**Note**

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string, which is used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (which is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

### YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of tab widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: BASE_SET_TITLE, SET_TAB_CURRENT, SET_TAB_MULTILINE.

## Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO return information that applies specifically to tab widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: TAB_CURRENT, TAB_MULTILINE, TAB_NUMBER.

## Widget Events Returned by Tab Widgets

Tab widgets generate events when a new tab is selected. The event structure returned by the WIDGET_EVENT function is defined by the following statement:

```
{WIDGET_TAB, ID:0L, TOP:0L, HANDLER:0L, TAB:0L}
```

ID is the widget ID of the button generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. TAB returns the zero-based index of the tab selected.

## Version History

Introduced: 5.6

## See Also

"Using Tab Widgets" in Chapter 27 of the *Building IDL Applications* manual

# WIDGET_TABLE

The WIDGET_TABLE function creates table widgets. Table widgets display two-dimensional data and allow in-place data editing. They can have one or more rows and columns, and automatically create scroll bars when viewing more data than can otherwise be displayed on the screen.

For a more detailed discussion of the table widget, along with examples, see "Using Table Widgets" in Chapter 27 of the *Building IDL Applications* manual.

### Note on Table Sizing

Table widgets are sized according to the value of the following pairs of keywords to WIDGET_TABLE, in order of precedence: SCR_XSIZE/SCR_YSIZE, XSIZE/YSIZE, X_SCROLL_SIZE/Y_SCROLL_SIZE, VALUE. If either dimension remains unspecified by one of the above keywords, the default value of six (columns or rows) is used when the table is created. If the width or height specified is less than the size of the table, scroll bars are added automatically.

## Syntax

*Result* = WIDGET_TABLE( *Parent* [, ALIGNMENT={0 | 1 | 2}] [, /ALL_EVENTS] [, AM_PM=*[string, string]*] [, COLUMN_LABELS=*string_array*] [, /COLUMN_MAJOR | , /ROW_MAJOR] [, COLUMN_WIDTHS=*array*] [, DAYS_OF_WEEK=*string_array*{7 names}] [, /DISJOINT_SELECTION] [, /EDITABLE] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*] [, FORMAT=*value*] [, FRAME=*width*] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, /KBRD_FOCUS_EVENTS] [, KILL_NOTIFY=*string*] [, MONTHS=*string_array*{12 names}] [, /NO_COPY] [, /NO_HEADERS] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, /RESIZEABLE_COLUMNS] [, /RESIZEABLE_ROWS{not supported in Windows}] [, RESOURCE_NAME=*string*] [, ROW_HEIGHTS=*array*{not supported in Windows}] [, ROW_LABELS=*string_array*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SCROLL] [, /SENSITIVE] [, /TRACKING_EVENTS] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, XOFFSET=*value*] [, XSIZE=*value*] [, X_SCROLL_SIZE=*width*] [, YOFFSET=*value*] [, YSIZE=*value*] [, Y_SCROLL_SIZE=*height*] )

## Return Value

The returned value of this function is the widget ID of the newly-created table widget.

# Arguments

## Parent

The widget ID of the parent widget for the new table widget.

# Keywords

## ALIGNMENT

Set this keyword equal to a scalar or 2-D array specifying the alignment of the text within each cell. An alignment of 0 (the default) aligns the left edge of the text with the left edge of the cell. An alignment of 2 right-justifies the text, while 1 results in text centered within the cell. If ALIGNMENT is set equal to a scalar, all table cells are aligned as specified. If ALIGNMENT is set equal to a 2-D array, the alignment of each table cell is governed by the corresponding element of the array.

## ALL_EVENTS

Set this keyword to cause to the text widget to generate events whenever the user changes the contents of a table cell.

**Note**

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_EVENTS and EDITABLE.

| Keywords | | Effects | |
|---|---|---|---|
| **ALL_EVENTS** | **EDITABLE** | **Input changes widget contents?** | **Type of events generated.** |
| Not set | Not set | No | None |
| Not set | Set | Yes | End-of-line insertion |
| Set | Not set | No | All events |
| Set | Set | Yes | All events |

*Table 106: Effects of using the ALL_EVENTS and EDITABLE keywords*

## AM_PM

Supplies a string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the FORMAT keyword.

## COLUMN_LABELS

Set this keyword equal to an array of strings used as labels for the columns of the table widget. The default labels are of the form “Column *n*”, where *n* is the column number. If this keyword is set to the empty string ( ' ' ), all column labels are set to be empty.

## COLUMN_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the VALUE keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one column’s data. Note that the structures must all be of the same type, and must have one field for each row in the table. If this keyword is not set, the table widget behaves as if the ROW_MAJOR keyword were set.

## COLUMN_WIDTHS

Set this keyword equal to an array of widths for the columns of the table widget. The widths are given in any of the units as specified with the UNITS keyword. If no width is specified for a column, that column is set to the default size, which varies by platform. If COLUMN_WIDTHS is set to a scalar value, all columns are set to that width.

## DAYS_OF_WEEK

Supplies a string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the FORMAT keyword.

## DISJOINT_SELECTION

Set this keyword to enable the ability to select multiple rectangular regions of cells. The regions can be overlapping, touching, or entirely distinct.

Setting this keyword changes the data structures returned by the TABLE_SELECT keyword to WIDGET_INFO and the GET_VALUE keyword to WIDGET_CONTROL.

Similarly, the data structures you supply via the SET_TABLE_SELECT and SET_VALUE keywords to WIDGET_CONTROL are different in disjoint mode.

See "Selection Modes" in Chapter 27 of the *Building IDL Applications* manual for additional details.

## EDITABLE

Set this keyword to allow direct user editing of the text widget contents. Normally, the text in text widgets is read-only. See ALL_EVENTS for a description of how EDITABLE interacts with the ALL_EVENTS keyword.

**Note**

The method by which text widgets are placed into edit mode is dependent upon the windowing system. See "Edit Mode" in the *Building IDL Applications* manual

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a "device font" (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See "About Device Fonts" on page 3962 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

A single font is shared by the row and column labels and by all of the cells in the widget.

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts; in general, the system default font is the font appropriate for the version of Windows in question.

## FORMAT

Set this keyword equal to a single string or array of strings that specify the format of data displayed within table cells. The string(s) are of the same form as used by the FORMAT keyword to the PRINT procedure, and the default format is the same as that used by the PRINT procedure.

**Warning**

If the format specified is incompatible with the data displayed in a table cell, an error message is generated. Since the error is generated *for each cell displayed*, the number of messages printed is potentially large, and can slow execution significantly. Note also that each time a new cell is displayed (when scroll bars are repositioned, for example), a new error is generated *for each cell displayed*.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget. Note that this keyword is only a “hint” to the toolkit, and may be ignored in some instances.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See “Widget Events Returned by Table Widgets” on page 2318 for more information.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## MONTHS

Supplies a string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the FORMAT keyword.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a "set" operation (using the UVALUE keyword to WIDGET_TABLE or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a "get" operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NO_HEADERS

Set this keyword to disable the display of the table widget's header area (where row and column labels are normally displayed).

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once

(because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (' '). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## RESIZEABLE_COLUMNS

Set this keyword to allow the user to change the size of columns using the mouse. Note that if the NO_HEADERS keyword was set, the columns cannot be resized interactively.

## RESIZEABLE_ROWS

Set this keyword to allow the user to change the size of rows using the mouse. Note that if the NO_HEADERS keyword was set, the rows cannot be resized interactively.

Under Microsoft Windows, the row size cannot be changed.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2139 for a complete discussion of this keyword.

## ROW_HEIGHTS

Set this keyword equal to an array of heights for the rows of the table widget. The heights are given in any of the units as specified with the UNITS keyword. If no height is specified for a row, that row is set to the default size, which varies by platform. If ROW_HEIGHTS is set to a scalar value, all of the row heights are set to that value.

**Note**

This keyword is not supported under Microsoft Windows.

## ROW_LABELS

Set this keyword equal to an array of strings to be used as labels for the rows of the table. If no label is specified for a row, it receives the default label "Row *n*", where *n*

is the row number. If this keyword is set to the empty string ( ' ' ), all row labels are set to be empty.

## ROW_MAJOR

This keyword is only valid if the table data is organized as a vector of structures rather than a two-dimensional array. See the VALUE keyword for details.

Set this keyword to specify that the data should be read into the table as if each element of the vector is a structure containing one row's data. Note that the structures must all be of the same type, and must have one field for each column in the table. This is the default behavior if neither the COLUMN_MAJOR or ROW_MAJOR keyword is set.

## SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). Note that the screen width of the widget *includes* the width of scroll bars, if any are present. Setting SCR_XSIZE overrides values set for the XSIZE or X_SCROLL_SIZE keywords. See "Note on Table Sizing" on page 2307.

## SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). Note that the screen height of the widget *includes* the height of scroll bars, if any are present. Setting SCR_YSIZE overrides values set for the YSIZE or Y_SCROLL_SIZE keywords. See "Note on Table Sizing" on page 2307.

## SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen. See "Note on Table Sizing" on page 2307

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

**Note**

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a table widget is either a two-dimensional array or a vector of structures.

If the value is specified as a two-dimensional array, all data must be of the same data type.

If the value is specified as a vector of structures, it can be displayed either in column-major or row-major format by setting either the COLUMN_MAJOR keyword or the ROW_MAJOR keyword. All of the structures must be of the same type, and must contain one field for each row (if COLUMN_MAJOR is set) or column (if ROW_MAJOR is set) in the table. If neither keyword is set, the data is displayed in row major format.

**Note**

If the VALUE keyword is not specified, the data in the created table will be of type STRING.

If none of [XY]SIZE, SCR_[XY]SIZE, or [XY]_SCROLL_SIZE is present, the size of the table is determined by the size of the array or vector of structures specified by VALUE. See "Note on Table Sizing" on page 2307.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The width of the widget in columns. If row labels are present, one column is automatically added to this value. See "Note on Table Sizing" on page 2307.

## X_SCROLL_SIZE

The XSIZE keyword always specifies the width of a widget, in columns. When the SCROLL keyword is specified, this size is not necessarily the same as the width of the visible area. The X_SCROLL_SIZE keyword allows you to set the width of the

scrolling viewport independently of the actual width of the widget. See “Note on Table Sizing” on page 2307.

Use of the X_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when X_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify Y_SCROLL_SIZE when specifying X_SCROLL_SIZE.

### YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

### YSIZE

The height of the widget in rows. If column labels are present, one row is automatically added to this value. See “Note on Table Sizing” on page 2307.

### Y_SCROLL_SIZE

The YSIZE keyword always specifies the height of a widget. in rows. When the SCROLL keyword is specified, this size is not necessarily the same as the height of the visible area. The Y_SCROLL_SIZE keyword allows you to set the height of the scrolling viewport independently of the actual width of the widget. See “Note on Table Sizing” on page 2307.

Use of the Y_SCROLL_SIZE keyword implies SCROLL. This means that scroll bars will be added in both the horizontal and vertical directions when Y_SCROLL_SIZE is specified. Because the default size of the scrolling viewport may differ between platforms, it is best to specify X_SCROLL_SIZE when specifying Y_SCROLL_SIZE.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of table widgets. In addition to those keywords that affect all widgets, the following are particularly useful: ALIGNMENT, ALL_TABLE_EVENTS, COLUMN_LABELS,

COLUMN_WIDTHS, DELETE_COLUMNS, DELETE_ROWS, EDITABLE, EDIT_CELL, FORMAT, GET_VALUE, INSERT_COLUMNS, INSERT_ROWS, KBRD_FOCUS_EVENTS, ROW_LABELS, ROW_HEIGHTS, SET_TABLE_SELECT, SET_TABLE_VIEW, SET_TEXT_SELECT, SET_VALUE, TABLE_BLANK, TABLE_DISJOINT_SELECTION, TABLE_XSIZE, TABLE_YSIZE, USE_TABLE_SELECT, USE_TEXT_SELECT.

# Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to table widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: COLUMN_WIDTHS, KBRD_FOCUS_EVENTS, ROW_HEIGHTS, TABLE_ALL_EVENTS, TABLE_DISJOINT_SELECTION, TABLE_EDITABLE, TABLE_EDIT_CELL, TABLE_SELECT, TABLE_VIEW, USE_TABLE_SELECT.

# Widget Events Returned by Table Widgets

There are several variations of the table widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the field type before referencing fields that are not present in all table event structures. The different table widget event structures are described below.

## Insert Single Character (TYPE = 0)

This is the type of structure returned when a single character is typed into a cell of a table widget by a user.

```
{WIDGET_TABLE_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
   CH:0B, X:0L, Y:0L }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character. X and Y give the zero-based address of the cell within the table.

## Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a cell by the window system.

```
{WIDGET_TABLE_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
   STR:'', X:0L, Y:0L}
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted. X and Y give the zero-based address of the cell within the table.

## Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a cell of a table widget.

```
{WIDGET_TABLE_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
   LENGTH:0L, X:0L, Y:0L}
```

OFFSET is the (zero-based) character position of the first character deleted. It is also the insertion position that will result when the next character is inserted. LENGTH gives the number of characters involved. X and Y give the zero-based address of the cell within the table.

## Text Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{WIDGET_TABLE_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3,
   OFFSET:0L, LENGTH:0L, X:0L, Y:0L}
```

The event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character to be selected. LENGTH gives the number of characters involved. A LENGTH of zero indicates that the widget has no selection, and that the insertion position is given by OFFSET. X and Y give the zero-based address of the cell within the table.

**Note**

Text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is not sent.

## Cell Selection (TYPE = 4)

This is the type of structure returned when range of cells is selected (highlighted) or deselected by the user.

```
{WIDGET_TABLE_CELL_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:4,
   SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The event announces a change in the currently selected cells. The range of cells selected is given by the zero-based indices into the table specified by the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields.

**Note**

If the table is in disjoint selection mode, selecting an additional region will result in a new WIDGET_TABLE_CELL_SEL event that reflects only the newly-selected cells. Use WIDGET_INFO, /TABLE_SELECT to obtain the entire selected region in disjoint selection mode.

When cells are deselected (either by changing the selection or by clicking in the upper left corner of the table) an event is generated in which the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields contain the value -1. This means that two WIDGET_TABLE_CELL_SEL events are generated when an existing selection is changed to a new selection. If your code pays attention to WIDGET_TABLE_CELL_SEL events, be sure to differentiate between select and deselect events.

**Note**

If the table is in disjoint selection mode and a new cell range is selected *starting on a previously-selected cell*, the previously selected cells are deselected but a WIDGET_TABLE_CELL_DESEL event is generated for the deselection rather than a WIDGET_TABLE_CELL_SEL event. See “Cell Deselection (Disjoint Mode) (TYPE = 9)” on page 2321 for details.

## Row Height Changed (TYPE = 6)

This is the type of structure returned when a row height is changed by the user.

```
{WIDGET_TABLE_ROW_HEIGHT, ID:0L, TOP:0L, HANDLER:0L, TYPE:6,
    ROW:0L, HEIGHT:0L}
```

The event announces that the height of the given row has been changed by the user. The ROW field contains the zero-based row number, and the HEIGHT field contains the new height.

## Column Width Changed (TYPE = 7)

This is the type of structure returned when a column width is changed by the user.

```
{WIDGET_TABLE_COL_WIDTH, ID:0L, TOP:0L, HANDLER:0L, TYPE:7,
   COL:0L, WIDTH:0L}
```

The event announces that the width of the given column has been changed by the user. The COL field contains the zero-based column number, and the WIDTH field contains the new width.

## Invalid Data (TYPE = 8)

This is the type of structure returned when the text entered by the user does not pass validation, and the user has finished editing the field (by hitting TAB or ENTER).

```
{WIDGET_TABLE_INVALID_ENTRY, ID:0L, TOP:0L, HANDLER:0L, TYPE:8,
   STR:'', X:0L, Y:0L}
```

When this event is generated, the cell's data is left unchanged. The invalid contents entered by the user is given as a text string in the STR field. The cell location is given by the X and Y fields.

## Cell Deselection (Disjoint Mode) (TYPE = 9)

This is the type of structure returned when selected cells are de-selected by the user *and the table is in disjoint selection mode*. It is identical to the (TYPE = 4) WIDGET_TABLE_CELL_SEL event structure except for the name and type value.

This event occurs when the user holds down the control key when starting a selection and the cell used to start the selection was already selected. In contrast, if the user starts a selection with the control key down but starts on a cell that was not selected, the normal WIDGET_TABLE_CELL_SEL is generated.

```
{WIDGET_TABLE_CELL_DESEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:9,
   SEL_LEFT:0L, SEL_TOP:0L, SEL_RIGHT:0L, SEL_BOTTOM:0L}
```

The range of cells selected is given by the zero-based indices into the table specified by the SEL_LEFT, SEL_TOP, SEL_RIGHT, and SEL_BOTTOM fields.

## Keyboard Focus Events

Table widgets return the following event structure when the keyboard focus changes and the base was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

ID is the widget ID of the table widget generating the event. TOP is the widget ID of the top level widget containing ID. HANDLER contains the widget ID of the widget associated with the handler routine. The ENTER field returns 1 (one) if the table widget is gaining the keyboard focus, or 0 (zero) if the table widget is losing the keyboard focus.

## Version History

Introduced: 5.0

DISJOINT_SELECTION keyword, Cell deselection (type 9) event added: 5.6

WIDGET_CONTROL

# WIDGET_TEXT

The WIDGET_TEXT function creates text widgets. Text widgets display text and optionally get textual input from the user. They can have 1 or more lines, and can optionally contain scroll bars to allow viewing more text than can otherwise be displayed on the screen.

## Syntax

*Result* = WIDGET_TEXT( *Parent* [, /ALL_EVENTS] [, /CONTEXT_EVENTS]
[, /EDITABLE] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, FONT=*string*]
[, FRAME=*width*] [, FUNC_GET_VALUE=*string*]
[, GROUP_LEADER=*widget_id*] [, /KBRD_FOCUS_EVENTS]
[, KILL_NOTIFY=*string*] [, /NO_COPY] [, /NO_NEWLINE]
[, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*]
[, RESOURCE_NAME=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*]
[, /SCROLL] [, /SENSITIVE] [, /TRACKING_EVENTS] [, UNAME=*string*]
[, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*value*] [, /WRAP]
[, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*] )

## Return Value

The returned value of this function is the widget ID of the newly-created text widget.

## Arguments

### Parent

The widget ID of the parent widget for the new text widget.

## Keywords

### ALL_EVENTS

Set this keyword to cause to the text widget to generate events whenever the user changes the contents of the text area.

If the EDITABLE keyword is set, an insert character event (TYPE=0) is generated when the user presses the RETURN or ENTER key in the text widget, even if the ALL_EVENTS keyword is not set. See the table below for details on the interaction between ALL_EVENTS and EDITABLE.

| Keywords | | Effects | |
|---|---|---|---|
| **ALL_EVENTS** | **EDITABLE** | **Input changes widget contents?** | **Type of events generated.** |
| Not set | Not set | No | None |
| Not set | Set | Yes | End-of-line insertion |
| Set | Not set | No | All events |
| Set | Set | Yes | All events |

*Table 107: Effects of using the ALL_EVENTS and EDITABLE keywords*

## CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU procedure within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 27 of the *Building IDL Applications* manual.

## EDITABLE

Set this keyword to allow direct user editing of the text widget contents. Normally, the text in text widgets is read-only. See ALL_EVENTS for a description of how EDITABLE interacts with the ALL_EVENTS keyword.

See "ALL_TEXT_EVENTS" on page 2174 for a description of how EDITABLE interacts with the ALL_TEXT_EVENTS keyword.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## FONT

The name of the font to be used by the widget. The font specified is a “device font” (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3962 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

**Note**

On Microsoft Windows platforms, if FONT is not specified, IDL uses the system default font. Different versions of Windows use different system default fonts.

## FRAME

The value of this keyword specifies the width of a frame in units specified by the UNITS keyword (pixels are the default) to be drawn around the borders of the widget.

**Note**

This keyword is only a “hint” to the toolkit, and may be ignored in some instances. Under Microsoft Windows, text widgets *always* have frames.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as “group leader” for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. It is not possible to remove a widget from an existing group.

## KBRD_FOCUS_EVENTS

Set this keyword to make the base return keyboard focus events whenever the keyboard focus of the base changes. See “Widget Events Returned by Text Widgets” on page 2330 for more information.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such “callback” procedure. It can be removed by setting the routine to the null string (`''`).

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique is fine for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copy the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. On a “set” operation (using the UVALUE keyword to WIDGET_TEXT or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. On a “get” operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NO_NEWLINE

Normally, when setting the value of a multi-line text widget, newline characters are automatically appended to the end of each line of text. Set this keyword to suppress this action.

## NOTIFY_REALIZE

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such "callback" procedure. It can be removed by setting the routine to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## RESOURCE_NAME

A string containing an X Window System resource name to be applied to the widget. See "RESOURCE_NAME" on page 2139 for a complete discussion of this keyword.

## SCR_XSIZE

Set this keyword to the desired "screen" width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired "screen" height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SCROLL

Set this keyword to give the widget scroll bars that allow viewing portions of the widget contents that are not currently on the screen.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse

cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget. Note that some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL procedure.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see “TRACKING_EVENTS” on page 2145 in the documentation for WIDGET_BASE.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO function with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (this is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

**Note**

This keyword does not affect all sizing operations. Specifically, the value of UNITS is ignored when setting the XSIZE or YSIZE keywords to WIDGET_TEXT.

## UVALUE

The “user value” to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the

convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

## VALUE

The initial value setting of the widget. The value of a text widget is the current text displayed by the widget.

VALUE can be either a string or an array of strings. Note that variables returned by the GET_VALUE keyword to WIDGET_CONTROL are always string arrays, even if a scalar string is specified in the call to WIDGET_TEXT.

## WRAP

Set this keyword to indicate that scrolling or multi-line text widgets should automatically break lines between words to keep the text from extending past the right edge of the text display area. Note that carriage returns are *not* automatically entered when lines wrap; the value of the text widget will remain a single-element array unless you explicitly enter a carriage return.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

## XSIZE

The width of the widget in characters. Note that the physical width of the text widget depends on both the value of XSIZE and on the size of the font used. The default value of XSIZE varies according to your windowing system. On Windows, the default size is roughly 20 characters. On Motif, the default size depends on the width of the text widget.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget programming.

### YSIZE

The height of the widget in text lines. Note that the physical height of the text widget depends on both the value of YSIZE and on the size of the font used. The default value of YSIZE is one line.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL procedure affect the behavior of text widgets. In addition to those keywords that affect all widgets, the following are particularly useful: ALL_TEXT_EVENTS, APPEND, CONTEXT_EVENTS, EDITABLE, GET_VALUE, KBRD_FOCUS_EVENTS, INPUT_FOCUS, NO_NEWLINE, SET_TEXT_SELECT, SET_TEXT_TOP_LINE, SET_VALUE, USE_TEXT_SELECT.

## Keywords to WIDGET_INFO

A number of keywords to the WIDGET_INFO function return information that applies specifically to text widgets. In addition to those keywords that apply to all widgets, the following are particularly useful: CONTEXT_EVENTS, KBRD_FOCUS_EVENTS, TEXT_ALL_EVENTS, TEXT_EDITABLE, TEXT_NUMBER, TEXT_OFFSET_TO_XY, TEXT_SELECT, TEXT_TOP_LINE, TEXT_XY_TO_OFFSET.

## Widget Events Returned by Text Widgets

There are several variations of the text widget event structure depending on the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all text event structures. The different text widget event structures are described below.

### Insert Single Character (TYPE = 0)

This is the type of structure returned when a single character is typed or pasted into a text widget by a user.

```
{ WIDGET_TEXT_CH, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, OFFSET:0L,
   CH:0B }
```

OFFSET is the (zero-based) insertion position that will result after the character is inserted. CH is the ASCII value of the character.

## Insert Multiple Characters (TYPE = 1)

This is the type of structure returned when multiple characters are pasted into a text widget by the window system.

```
{ WIDGET_TEXT_STR, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, OFFSET:0L,
   STR:'' }
```

OFFSET is the (zero-based) insertion position that will result after the text is inserted. STR is the string to be inserted.

## Delete Text (TYPE = 2)

This is the type of structure returned when any amount of text is deleted from a text widget.

```
{ WIDGET_TEXT_DEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:2, OFFSET:0L,
   LENGTH:0L }
```

OFFSET is the (zero-based) character position of the first character to be deleted. It is also the insertion position that will result when the characters have been deleted. LENGTH gives the number of characters involved. A LENGTH of zero indicates that no characters were deleted.

## Selection (TYPE = 3)

This is the type of structure returned when an area of text is selected (highlighted) by the user.

```
{ WIDGET_TEXT_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:3, OFFSET:0L,
   LENGTH:0L }
```

The event announces a change in the insertion point. OFFSET is the (zero-based) character position of the first character to be selected. LENGTH gives the number of characters involved. A LENGTH of zero indicates that no characters are selected, and the new insertion position is given by OFFSET.

Note that text insertion, text deletion, or any change in the current insertion point causes any current selection to be lost. In such cases, the loss of selection is implied by the text event reporting the insert/delete/movement and a separate zero length selection event is *not* sent.

### Keyboard Focus Events

Text widgets return the following event structure when the keyboard focus changes and the base was created with the KBRD_FOCUS_EVENTS keyword set:

```
{ WIDGET_KBRD_FOCUS, ID:0L, TOP:0L, HANDLER:0L, ENTER:0 }
```

The first three fields are the standard fields found in every widget event. The ENTER field returns 1 (one) if the text widget is gaining the keyboard focus, or 0 (zero) if the text widget is losing the keyboard focus.

### Context Menu Events

Text widgets return the following event structure when the user clicks the right mouse button and the text widget was created with the CONTEXT_EVENTS keyword set:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, measured from the upper left corner of the text widget.

## Version History

Introduced: Pre 4.0

CW_FIELD, XDISPLAYFILE

# WIDGET_TREE

The WIDGET_TREE function is used to create and populate a tree widget. The tree widget presents a hierarchical view that can be used to organize a wide variety of data structures and information.

The WIDGET_TREE function performs two separate tasks: creating the tree widget and populating the tree widget with *nodes* (branches and leaves).

For a more detailed discussion of the tree widget, along with examples, see "Using Tree Widgets" in Chapter 27 of the *Building IDL Applications* manual.

## Syntax

*Result* = WIDGET_TREE( *Parent* [, /ALIGN_BOTTOM | , /ALIGN_CENTER | , /ALIGN_LEFT | , /ALIGN_RIGHT | , /ALIGN_TOP] [, BITMAP=*array*] [, /CONTEXT_EVENTS] [, EVENT_FUNC=*string*] [, EVENT_PRO=*string*] [, /EXPANDED] [, /FOLDER] [, FUNC_GET_VALUE=*string*] [, GROUP_LEADER=*widget_id*] [, KILL_NOTIFY=*string*] [, /MULTIPLE] [, /NO_COPY] [, NOTIFY_REALIZE=*string*] [, PRO_SET_VALUE=*string*] [, SCR_XSIZE=*width*] [, SCR_YSIZE=*height*] [, /SENSITIVE] [, /TRACKING_EVENTS] [, /TOP] [, UNAME=*string*] [, UNITS={0 | 1 | 2}] [, UVALUE=*value*] [, VALUE=*string*] [, XOFFSET=*value*] [, XSIZE=*value*] [, YOFFSET=*value*] [, YSIZE=*value*] )

## Return Value

The returned value of this function is the widget ID of the newly-created tree widget.

## Arguments

### Parent

The widget ID of the parent for the new tree widget. *Parent* can be either a base widget or a tree widget.

- If *Parent* is a base widget, WIDGET_TREE will create a tree widget that contains no other tree widgets. This type of tree widget is referred to as a *root node*.
- If *Parent* is a tree widget, WIDGET_TREE will create a new tree widget (called a *node*) in the specified tree widget.

**Note**

With the exception of the first tree widget created (the *root node*, whose *Parent* is a base widget), a tree widget (or *node*) must be created with the FOLDER keyword in order to serve as the *Parent* for other tree widgets.

# Keywords

## ALIGN_BOTTOM

Set this keyword to align the new widget with the bottom of its parent base. To take effect, the parent must be a ROW base.

## ALIGN_CENTER

Set this keyword to align the new widget with the center of its parent base. To take effect, the parent must be a ROW or COLUMN base. In ROW bases, the new widget will be vertically centered. In COLUMN bases, the new widget will be horizontally centered.

## ALIGN_LEFT

Set this keyword to align the new widget with the left side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_RIGHT

Set this keyword to align the new widget with the right side of its parent base. To take effect, the parent must be a COLUMN base.

## ALIGN_TOP

Set this keyword to align the new widget with the top of its parent base. To take effect, the parent must be a ROW base.

## BITMAP

Set this keyword equal to a 16x16x3 array representing an RGB image that will be displayed next to the node in the tree widget.

## CONTEXT_EVENTS

Set this keyword to cause context menu events (or simply context events) to be issued when the user clicks the right mouse button over the widget. Set the keyword to 0 (zero) to disable such events. Context events are intended for use with context-

sensitive menus (also known as pop-up or shortcut menus); pass the context event ID to the WIDGET_DISPLAYCONTEXTMENU within your widget program's event handler to display the context menu.

For more on detecting and handling context menu events, see "Context-Sensitive Menus" in Chapter 27 of the *Building IDL Applications* manual.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

## EVENT_FUNC

A string containing the name of a function to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EVENT_PRO

A string containing the name of a procedure to be called by the WIDGET_EVENT function when an event arrives from a widget in the widget hierarchy rooted at the newly-created widget.

## EXPANDED

If the tree node being created is a *folder* (specified by the FOLDER keyword), set this keyword to cause the folder to be initially displayed expanded, showing all of its immediate child entries. By default, folders are initially displayed collapsed.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

## FOLDER

Set this keyword to cause the tree node being created to act as a *folder* (that is, as a branch of the tree rather than a leaf).

**Note**

With the exception of the root node (the tree widget whose *Parent* widget is a base widget), only tree nodes that have the FOLDER keyword set can act as the parent for other tree widgets.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

## FUNC_GET_VALUE

A string containing the name of a function to be called when the GET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this

technique allows you to change the value that should be returned for a widget. Compound widgets use this ability to define their values transparently to the user.

## GROUP_LEADER

The widget ID of an existing widget that serves as group leader for the newly-created widget. When a group leader is killed, for any reason, all widgets in the group are also destroyed.

A given widget can be in more than one group. The WIDGET_CONTROL procedure can be used to add additional group associations to a widget. You cannot remove a widget from an existing group.

## KILL_NOTIFY

Set this keyword to a string that contains the name of a procedure to be called automatically when the specified widget dies. Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). Note that the procedure specified is used only if you are not using the XMANAGER procedure to manage your widgets.

The callback routine is called with the widget identifier as its only argument. At that point, the widget identifier can only be used with the WIDGET_CONTROL procedure to get or set the user value. All other requests that require a widget ID are disallowed for the target widget. The callback is not issued until the WIDGET_EVENT function is called.

If you use the XMANAGER procedure to manage your widgets, the value of this keyword is overwritten. Use the CLEANUP keyword to XMANAGER to specify a procedure to be called when a managed widget dies.

## MULTIPLE

Set this keyword to enable multiple selection operations in the tree widget. If enabled, multiple elements in the tree widget can be selected at one time by holding down the **Control** or **Shift** key while clicking the left mouse button.

This keyword is only valid if the *Parent* of the tree widget is a base widget.

## NO_COPY

Usually, when setting or getting widget user values, either at widget creation or using the SET_UVALUE and GET_UVALUE keywords to WIDGET_CONTROL, IDL makes a second copy of the data being transferred. Although this technique works well for small data, it can have a significant memory cost when the data being copied is large.

If the NO_COPY keyword is set, IDL handles these operations differently. Rather than copying the source data, it takes the data away from the source and attaches it directly to the destination. This feature can be used by compound widgets to obtain state information from a UVALUE without all the memory copying that would otherwise occur. However, it has the side effect of causing the source variable to become undefined. Upon a set operation (using the UVALUE keyword to WIDGET_TAB or the SET_UVALUE keyword to WIDGET_CONTROL), the variable passed as value becomes undefined. Upon a get operation (GET_UVALUE keyword to WIDGET_CONTROL), the user value of the widget in question becomes undefined.

## NOTIFY_REALIZE

Set this keyword to a string containing the name of a procedure to be called automatically when the specified widget is realized. This callback occurs just once (because widgets are realized only once). Each widget is allowed a single such callback procedure. This callback procedure can be removed by setting the routine name to the null string (`''`). The callback routine is called with the widget ID as its only argument.

## PRO_SET_VALUE

A string containing the name of a procedure to be called when the SET_VALUE keyword to the WIDGET_CONTROL procedure is called for this widget. Using this technique allows you to designate a routine that sets the value for a widget. Compound widgets use this ability to define their values transparently to the user.

## SCR_XSIZE

Set this keyword to the desired screen width of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the XSIZE keyword.

## SCR_YSIZE

Set this keyword to the desired screen height of the widget, in units specified by the UNITS keyword (pixels are the default). In many cases, setting this keyword is the same as setting the YSIZE keyword.

## SENSITIVE

Set this keyword to control the initial sensitivity state of the widget.

If SENSITIVE is zero, the widget becomes insensitive. If nonzero, it becomes sensitive. When a widget is sensitive, it has normal appearance and can receive user input. For example, a sensitive button widget can be activated by moving the mouse cursor over it and pressing a mouse button. When a widget is insensitive, it indicates the fact by changing its appearance, looking disabled, and it ignores any input.

Sensitivity can be used to control when a user is allowed to manipulate the widget.

**Note**

Some widgets do not change their appearance when they are made insensitive, but they cease generating events.

After creating the widget hierarchy, you can change the sensitivity state using the SENSITIVE keyword with the WIDGET_CONTROL.

## TRACKING_EVENTS

Set this keyword to cause widget tracking events to be issued for the widget whenever the mouse pointer enters or leaves the region covered by that widget. For the structure of tracking events, see "TRACKING_EVENTS" on page 2145 in the documentation for WIDGET_BASE.

## TOP

Set this keyword to cause the tree node being created to be inserted as the parent node's top entry. By default, new nodes are inserted as the parent node's bottom entry.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

## UNAME

Set this keyword to a string that can be used to identify the widget in your code. You can associate a name with each widget in a specific hierarchy, and then use that name to query the widget hierarchy and get the correct widget ID.

To query the widget hierarchy, use the WIDGET_INFO with the FIND_BY_UNAME keyword. The UNAME should be unique to the widget hierarchy because the FIND_BY_UNAME keyword returns the ID of the first widget with the specified name.

## UNITS

Set UNITS equal to 0 (zero) to specify that all measurements are in pixels (which is the default), to 1 (one) to specify that all measurements are in inches, or to 2 (two) to specify that all measurements are in centimeters.

## UVALUE

The user value to be assigned to the widget.

Each widget can contain a user-specified value of any data type and organization. This value is not used by the widget in any way, but exists entirely for the convenience of the IDL programmer. This keyword allows you to set this value when the widget is first created.

If UVALUE is not present, the widget's initial user value is undefined.

## VALUE

Set this keyword equal to a string containing the text that will be displayed next to the tree node. If this keyword is not set, the default value `Tree` is used.

This keyword is only valid if the *Parent* of the tree widget is another tree widget.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

## XSIZE

The width of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the *upper left* corner of the parent widget.

Specifying an offset relative to a row or column major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. You should avoid using this style of widget programming.

### YSIZE

The height of the widget in units specified by the UNITS keyword (pixels are the default). Most widgets attempt to size themselves to fit the situation. However, if the desired effect is not produced, use this keyword to override it. This keyword is only a hint to the toolkit and may be ignored in some situations.

## Keywords to WIDGET_CONTROL

A number of keywords to the WIDGET_CONTROL affect the behavior of tree widgets. In addition to those keywords that affect all widgets, the following keywords are particularly useful: SET_TREE_BITMAP, SET_TREE_EXPANDED, SET_TREE_SELECT, SET_TREE_VISIBLE.

## Keywords to WIDGET_INFO

Some keywords to the WIDGET_INFO return information that applies specifically to tree widgets. In addition to those keywords that apply to all widgets, the following keywords are particularly useful: TREE_EXPANDED, TREE_SELECT, and TREE_ROOT.

## Widget Events Returned by Tree Widgets

Several variations of the tree widget event structure depend upon the specific event being reported. All of these structures contain the standard three fields (ID, TOP, and HANDLER) as well as an integer TYPE field that indicates which type of structure has been returned. Programs should always check the type field before referencing fields that are not present in all tree event structures. The different tree widget event structures are described below.

### Select (TYPE = 0)

This structure is returned when the currently selected node in the tree widget changes:

```
{WIDGET_TREE_SEL, ID:0L, TOP:0L, HANDLER:0L, TYPE:0, CLICKS:0L}
```

The CLICKS field indicates the number of mouse-button clicks that occurred when the event took place. This field contains 1 (one) when the item is selected, or 2 when the user double-clicks on the item.

### Expand (TYPE = 1)

This structure is returned when a folder in the tree widget expands or collapses:

```
{WIDGET_TREE_EXPAND, ID:0L, TOP:0L, HANDLER:0L, TYPE:1, EXPAND:0L}
```

The EXPAND field contains 1 (one) if the folder expanded or 0 (zero) if the folder collapsed.

### Context Menu Events

Tree widgets return the following event structure when the user clicks the right mouse button and the tree widget was created with the CONTEXT_EVENTS keyword set:

```
{WIDGET_CONTEXT, ID:0L, TOP:0L, HANDLER:0L, X:0L, Y:0L}
```

The first three fields are the standard fields found in every widget event. The X and Y fields give the device coordinates at which the event occurred, and are measured from the upper left corner of the tree widget.

## Version History

Introduced: 5.6

## See Also

"Using Tree Widgets" in Chapter 27 of the *Building IDL Applications* manual

# WINDOW

The WINDOW procedure creates a window for the display of graphics or text. It is only necessary to use WINDOW if more than one simultaneous window or a special size window is desired because a window is created automatically the first time any display procedure attempts to access the window system. The newly-created window becomes the current window, and the system variable !D.WINDOW is set to that window's window index. (See the description of the WSET procedure for a discussion of the current IDL window.)

The behavior of WINDOW varies slightly depending on the window system in effect. See the discussion of IDL graphics devices in Appendix A, "IDL Graphics Devices" for additional details.

## Syntax

WINDOW [, *Window_Index*] [, COLORS=*value*] [, /FREE] [, /PIXMAP] [, RETAIN={0 | 1 | 2}] [, TITLE=*string*] [, XPOS=*value*] [, YPOS=*value*] [, XSIZE=*pixels*] [, YSIZE=*pixels*]

## Arguments

### Window_Index

The window index for the newly-created window. A window index is an integer value between 0 and 31 that is used to refer to the window. If this parameter is omitted, window index 0 is used. If the value of *Window_Index* specifies an existing window, the existing window is deleted and a new one is created. If you need to create more than 32 windows, use the FREE keyword described below.

## Keywords

### COLORS

**Note**

This keyword is ignored under Microsoft Windows.

The maximum number of color table indices to be used when drawing. This keyword has an effect only if supplied when the first window is created. If COLORS is not present when the first window is created, all or most of the available color indices are allocated depending upon the window system in use.

To use monochrome windows on a color display in X Windows, use COLORS = 2 when creating the first window. One color table is maintained for all windows. A negative value for COLORS specifies that all but the given number of colors from the shared color table should be allocated.

Although this keyword is ignored under Microsoft Windows, we could use the following code to use a monochrome window on all platforms:

```
WINDOW, COLORS=2 ; ignored on Windows
white=!D.N_COLORS-1
PLOT, FINDGEN(20), COLOR=white
```

## FREE

Set this keyword to create a window using the smallest unused window index above 32. If this keyword is present, the *Window_Index* argument can be omitted. The default position of the new window is opposite that of the current window. Using the FREE keyword allows the creation of a large number of windows. The system variable !D.WINDOW is set to the index of the newly-created window.

## PIXMAP

Set the PIXMAP keyword to specify that the window being created is actually an invisible portion of the display memory called a pixmap.

## RETAIN

Set this keyword to 0, 1, or 2 to specify how backing store should be handled for the window:

- 0 = no backing store
- 1 = requests that the server or window system provide backing store
- 2 = specifies that IDL provide backing store directly

See “Backing Store” on page 3824 for details.

## TITLE

A scalar string that contains the window’s label. If not specified, the window is given a label of the form “IDL *n*”, where *n* is the index number of the window. For example, to create a window with the label “IDL Graphics”, enter:

```
WINDOW, TITLE='IDL Graphics'
```

## XPOS

The X position of the window, specified in device coordinates. On Motif platforms, XPOS specifies the X position of the *lower* left corner and is measured from the lower left corner of the screen. On Windows platforms, XPOS specifies the X position of the *upper* left corner and is measured from the upper left corner of the screen. That is, specifying

```
WINDOW, XPOS = 0, YPOS = 0
```

will create a window in the lower left corner on Motif machines and in the upper left corner on Windows machines.

If no position is specified, the position of the window is determined from the value of Window Index using the following rules:

- Window 0 is placed in the upper right hand corner.
- Even numbered windows are placed on the top half of the screen and odd numbered windows are placed on the bottom half.
- Windows 0,1,4,5,8, and 9 are placed on the right side of the screen and windows 2,3,6, and 7 are placed on the left.

**Note**

The order of precedence (highest to lowest) for positioning windows is: XPOS/YPOS keywords to WINDOW, Tile/Cascade IDE graphics (user system) preferences, optional index argument to WINDOW. Also realize that setting LOCATION is only a request to the Window manager and may not always be honored due to system peculiarities.

## YPOS

The Y position of the window, specified in device coordinates. See the description of XPOS for details.

## XSIZE

The width of the window in pixels.

## YSIZE

The height of the window in pixels.

## Examples

Create graphics window number 0 with a size of 400 by 400 pixels and a title that reads “Square Window” by entering:

```
WINDOW, 0, XSIZE=400, YSIZE=400, TITLE='Square Window'
```

## Version History

Introduced: Original

# WRITE_BMP

The WRITE_BMP procedure writes an image and its color table vectors to a Microsoft Windows Version 3 device independent bitmap file (.BMP).

WRITE_BMP does not handle 1-bit-deep images or compressed images, and is not fast for 4-bit images. The algorithm works best on images where the number of bytes in each scan-line is evenly divisible by 4.

This routine is written in the IDL language. Its source code can be found in the file `write_bmp.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

WRITE_BMP, *Filename*, *Image*[, *R*, *G*, *B*] [, /FOUR_BIT] [, IHDR=*structure*] [, HEADER_DEFINE=*h*{define *h* before call}] [, /RGB]

## Arguments

### Filename

A scalar string containing the full pathname of the bitmap file to write.

### Image

The array to write into the new bitmap file. The array should be scaled into a range of bytes for 8- and 24-bit deep images. Scale to 0-15 for 4-bit deep images. If the image has 3 dimensions and the first dimension is 3, a 24-bit deep bitmap file is created.

**Note**

For 24-bit images, color interleaving is blue, green, red: *Image*[0, *i*, *j*] = blue, *Image*[1, *i*, *j*] = green, *Image*[2, *i*, *j*] = red.

### R, G, B

Color tables. If omitted, the colors loaded in the COLORS common block are used.

# Keywords

## FOUR_BIT

Set this keyword to write as a 4-bit device independent bitmap. If omitted or zero, an 8-bit deep bitmap is written.

## IHDR

Set this keyword to a BITMAPINFOHEADER structure containing the file header fields that are not obtained from the image itself. The fields in this structure that can be set are: `bi{XY}PelsPerMeter`, `biClrUsed`, and `biClrImportant`.

## HEADER_DEFINE

If this keyword is set, WRITE_BMP returns an empty BITMAPINFOHEADER structure, containing zeros. No other actions are performed. This structure may be then modified with the pertinent fields and passed in via the IHDR keyword parameter. See the Microsoft Windows Programmers Reference Guide for a description of each field in the structure.

Note: this parameter must be defined *before* the call. For example:

```
H = 0
WRITE_BMP, HEADER_DEFINE = H
```

## RGB

Set this keyword to reverse the color interleaving for 24-bit images to red, green, blue: *Image*[0, *i*, *j*] = red, *Image*[1, *i*, *j*] = green, *Image*[2, *i*, *j*] = blue. By default, 24-bit images are written with color interleaving of blue, green, red.

# Examples

The following command captures the contents of the current IDL graphics window and saves it to a Microsoft Windows Bitmap file with the name `test.bmp`. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_BMP, 'test.bmp', TVRD()
```

The following commands scale an image to 0-15, and then write a 4-bit BMP file, using a grayscale color table:

```
; Create a ramp from 0 to 255:
r = BYTSCL(INDGEN(16))

WRITE_BMP, 'test.bmp', BYTSCL(Image, MAX=15), r, r, r, /FOUR
```

## Version History

Introduced: Pre 4.0

READ_BMP, QUERY_* Routines

# WRITE_IMAGE

The WRITE_IMAGE procedure writes an image and its color table vectors, if any, to a file of a specified type. WRITE_IMAGE can write most types of image files supported by IDL.

## Syntax

WRITE_IMAGE, *Filename*, *Format*, *Data* [, *Red*, *Green*, *Blue*] [, /APPEND]

## Arguments

### Filename

A scalar string containing the name of the file to write.

### Format

A scalar string containing the name of the file format to write. The following are the supported formats:

- BMP
- JPEG
- PNG
- PPM
- SRF
- TIFF

### Data

An IDL variable containing the image data to write to the file.

### Red

An optional vector containing the red channel of the color table if a colortable exists.

### Green

An optional vector containing the green channel of the color table if a colortable exists.

### Blue

An optional vector containing the blue channel of the color table if a colortable exists.

## Keywords

### APPEND

Set this keyword to force the image to be appended to the file instead of overwriting the file. APPEND may be used with image formats that supports multiple images per file and is ignored for formats that support only a single image per file.

## Version History

Introduced: 5.3

# WRITE_JPEG

The WRITE_JPEG procedure writes compressed images to files. JPEG (Joint Photographic Experts Group) is a standardized compression method for full-color and gray-scale images. This procedure is based in part on the work of the Independent JPEG Group.

As the Independent JPEG Group states, JPEG is intended for real-world scenes (such as digitized photographs). Line art, such as drawings or IDL plots, and other unrealistic images are not its strong suit. Note also that JPEG is a lossy compression scheme. That is, the output image is *not* identical to the input image. Hence you cannot use JPEG if you must have identical output bits. On typical images of real-world scenes, however, very good compression levels can be obtained with no visible change, and amazingly high compression levels are possible if you can tolerate a low-quality image. You can trade off output image quality against compressed file size by adjusting a compression parameter. Files are encoded in JFIF, the JPEG File Interchange Format; however, such files are usually simply called JPEG files.

If you need to store images in a format that uses lossless compression, consider using the WRITE_PNG procedure. This procedure writes a Portable Network Graphics (PNG) file using lossless compression with either 8 or 16 data bits per channel. To store 8-bit or 24-bit images without compression, consider using WRITE_BMP (for Microsoft Bitmap format files) or WRITE_TIFF (to write Tagged Image Format Files).

For a short technical introduction to the JPEG compression algorithm, see: Wallace, Gregory K. “The JPEG Still Picture Compression Standard”, *Communications of the ACM*, April 1991 (vol. 34, no. 4), pp. 30-44.

**Note**

All JPEG files consist of byte data. Input data is converted to bytes before being written to a JPEG file.

## Syntax

WRITE_JPEG [, *Filename* | , UNIT=*lun*] , *Image* [, /ORDER] [, /PROGRESSIVE] [, QUALITY=*value*{0 to 100}] [, TRUE={1 | 2 | 3}]

# Arguments

## Filename

A string containing the name of file to be written in JFIF (JPEG) format. If this parameter is not present, the UNIT keyword must be specified.

## Image

A byte array of either two or three dimensions, containing the image to be written. Grayscale images must have two dimensions. TrueColor images must have three dimensions with the index of the dimension that contains the color specified with the TRUE keyword.

# Keywords

## ORDER

JPEG/JFIF images are normally written in top-to-bottom order. If the image array is in the standard IDL order (i.e., from bottom-to-top) set ORDER to 0, its default value. If the image array is in top-to-bottom order, ORDER must be set to 1.

## PROGRESSIVE

Set this keyword to write the image as a series of scans of increasing quality. When used with a slow communications link, a decoder can generate a low-quality image very quickly, and then improve its quality as more scans are received.

**Warning**

Not all JPEG applications can handle progressive JPEG files, and it is up the JPEG reader to progressively display the JPEG image. For example, IDL's READ_JPEG routine ignores the progressive readout request and reads the entire image in at the first reading.

## QUALITY

This keyword specifies the quality index, in the range of 0 (terrible) to 100 (excellent) for the JPEG file. The default value is 75, which corresponds to very good quality. Lower values of QUALITY produce higher compression ratios and smaller files.

### TRUE

This keyword specifies the index, starting at 1, of the dimension over which the color is interleaved. For example, for an image that is pixel interleaved and has dimensions of (3, *m*, *n*), set TRUE to 1. Specify 2 for row-interleaved images (*m*, 3, *n*); and 3 for band-interleaved images (*m*, *n*, 3). If TRUE is not set, the image is assumed to have no interleaving (it is not a TrueColor image).

### UNIT

This keyword designates the logical unit number of an already open file to receive the output, allowing multiple JFIF images per file or the embedding of JFIF images in other data files. If this keyword is used, *Filename* should not be specified.

**Note**

When opening a file intended for use with the UNIT keyword, if the filename does not end in `.jpg`, or `.jpeg`, you must specify the STDIO keyword to OPEN in order for the file to be compatible with WRITE_JPEG.

## Examples

Write the image contained in the array A, using JPEG compression with a quality index of 25. The image is stored in bottom-to-top order:

```
image = DIST(100)
WRITE_JPEG, 'test1.jpg', image, QUALITY=25
```

Write a TrueColor image to a JPEG file. The image is contained in the band-interleaved array A with dimensions (*m*, *n*, 3). Assume it is stored in top-to-bottom order:

```
WRITE_JPEG, 'test2.jpg', image, TRUE=3, /ORDER
```

## Version History

Introduced: Pre 4.0

## See Also

READ_JPEG, QUERY_* Routines

# WRITE_NRIF

The WRITE_NRIF procedure writes an image and its color table vectors to an NCAR Raster Interchange Format (NRIF) rasterfile.

WRITE_NRIF only writes 8- or 24-bit deep rasterfiles of types “Indexed Color” (8-bit) and “Direct Color integrated” (24-bit). The color map is included only for 8-bit files.

See the document “NCAR Raster Interchange Format and TAGS Raster Reference Manual,” available from the Scientific Computing Division, National Center for Atmospheric Research, Boulder, CO, 80307-3000, for information on the structure of NRIF files.

This routine is written in the IDL language. Its source code can be found in the file `write_nrif.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

WRITE_NRIF, *File*, *Image* [, *R*, *G*, *B*]

## Arguments

### File

A scalar string containing the full path name of the NRIF file to write.

### Image

The byte array to be written to the NRIF file. If *Image* has the dimensions (*n*,*m*), an 8-bit NRIF file with color tables is created. If *Image* has the dimensions (3,*n*,*m*), a 24-bit NRIF file is created, where each byte triple represents the red, green, and blue intensities at (*n*,*m*) on a scale from 0 to 255. The NRIF image will be rendered from bottom to top, in accordance with IDL standards.

### R, G, B

The Red, Green, and Blue color vectors to be used as a color table with 8-bit images. If color vectors are supplied, they are included in the output (8-bit images only). If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_NRIF calls LOADCT to load the grayscale entry (table 0).

**Note**

WRITE_NRIF does not recognize color vectors loaded directly using TVLCT, so if a custom color table is desired and it is not convenient to use XPALETTE, include the R, G, and B vectors that were used to create the color table.

## Version History

Introduced: Pre 4.0

# WRITE_PICT

The WRITE_PICT procedure writes an image and its color table vectors to a PICT (version 2) format image file. The PICT format is used by Apple Macintosh computers.

Note: WRITE_PICT only works with 8-bit displays

This routine is written in the IDL language. Its source code can be found in the file `write_pict.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

WRITE_PICT, *Filename* [, *Image*, *R*, *G*, *B*]

## Arguments

### Filename

A scalar string containing the full pathname of the PICT file to write.

### Image

The byte array to be written to the PICT file. If *Image* is omitted, the entire current graphics window is read into an array and written to the PICT file.

### R, G, B

The Red, Green, and Blue color vectors to be written to the PICT file. If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_PICT calls LOADCT to load the grayscale entry (table 0).

## Examples

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_PICT, 'test.pict', TVRD()
```

## Version History

Introduced: Pre 4.0

## See Also

READ_PICT, QUERY_* Routines

# WRITE_PNG

The WRITE_PNG procedure writes a 2-D or 3-D IDL variable into a Portable Network Graphics (PNG) file. The data in the file is stored using lossless compression with either 8 or 16 data bits per channel, based on the input IDL variable type. 3-D IDL variables must have the number of channels as their leading dimension (pixel interleaved). For BYTE format 2-D IDL variables, an optional palette may be stored in the image file along with a list of pixel values which are to be considered transparent by a reading program.

**Note**

IDL supports version 1.0.5 of the PNG Library.

## Syntax

WRITE_PNG, *Filename*, *Image*[, *R*, *G*, *B*] [, /ORDER] [, /VERBOSE] [, TRANSPARENT=*array*]

## Arguments

### Filename

A scalar string containing the full pathname of the PNG file to write.

### Image

The array to write into the new PNG file. If *Image* is one of the integer data types, it is converted to type unsigned integer (UINT) and written out at 16 data bits per channel. All other data types are converted to bytes and written out at 8-bits per channel.

**Note**

If *Image* is two-dimensional (single-channel) and *R*, *G*, and *B* are provided, all input data types (including integer) are converted to bytes and written out as 8-bit data.

### R, G, B

For single-channel images, *R*, *G*, and *B* should contain the red, green, and blue color vectors, respectively. For multi-channel images, these arguments are ignored.

# Keywords

## ORDER

Set this keyword to indicate that the rows of the image should be written from bottom to top. The rows are written from top to bottom by default. ORDER provides compatibility with PNG files written using versions of IDL prior to IDL 5.4, which wrote PNG files from bottom to top.

## VERBOSE

Produces additional diagnostic output during the write.

## TRANSPARENT

Set this keyword to an array of pixel index values which are to be treated as "transparent" for the purposes of image display. This keyword is valid only if *Image* is a single-channel (color indexed) image and the R, G, B palette is provided.

# Examples

Create an RGBA (16-bits/channel) and a Color Indexed (8-bits/channel) image with a palette.

```
rgbdata = UINDGEN(4,320,240)
cidata = BYTSCL(DIST(256))
red = INDGEN(256)
green = INDGEN(256)
blue = INDGEN(256)
WRITE_PNG,'rgb_image.png',rgbdata
WRITE_PNG,'ci_image.png',cidata,red,green,blue

; Query and Read the data:
names = ['rgb_image.png','ci_image.png','unknown.png']
FOR i=0,N_ELEMENTS(names)-1 DO BEGIN
   ok = QUERY_PNG(names[i],s)
   IF (ok) THEN BEGIN
      HELP,s,/STRUCTURE
      IF (s.HAS_PALETTE) THEN BEGIN
         img = READ_PNG(names[i],rpal,gpal,bpal)
         HELP,img,rpal,gpal,bpal
      ENDIF ELSE BEGIN
         img = READ_PNG(names[i])
         HELP,img
      ENDELSE
   ENDIF ELSE BEGIN
```

```
      PRINT,names[i],' is not a PNG file'
    ENDELSE
  ENDFOR
```

## Version History

Introduced: 5.2

## See Also

READ_PNG, QUERY_* Routines

# WRITE_PPM

The WRITE_PPM procedure writes an image to a PPM (TrueColor) or PGM (gray scale) file. This routine is written in the IDL language. Its source code can be found in the file `write_ppm.pro` in the `lib` subdirectory of the IDL distribution.

**Note**

WRITE_PPM only writes 8-bit deep PGM/PPM files of the standard type. Images should be ordered so that the first row is the top row.

PPM/PGM format is supported by the PBMPLUS toolkit for converting various image formats to and from portable formats, and by the Netpbm package.

## Syntax

WRITE_PPM, *Filename*, *Image* [, /ASCII]

## Arguments

### Filename

A scalar string specifying the full pathname of the PPM or PGM file to write.

### Image

The 2D (gray scale) or 3D (TrueColor) array to be written to a file.

## Keywords

### ASCII

Set this keyword to force WRITE_PPM to use formatted ASCII input/output to write the image data. The default is to use the far more efficient binary input/output (RAWBITS) format.

## Examples

```
image = DIST(100)
WRITE_PPM, 'file.ppm', image
```

## Version History

Introduced: 4.0

## See Also

READ_PPM, QUERY_* Routines

# WRITE_SPR

The WRITE_SPR procedure writes a row-indexed sparse array structure to a specified file. Row-indexed sparse arrays are created using the SPRSIN function.

## Syntax

WRITE_SPR, *AS, Filename*

## Arguments

### AS

A row-indexed sparse array created by SPRSIN.

### Filename

The name of the file that will contain AS.

## Keywords

None.

## Examples

```
; Create an array:
A = [[3.,0., 1., 0., 0.],$
     [0.,4., 0., 0., 0.],$
     [0.,7., 5., 9., 0.],$
     [0.,0., 0., 0., 2.],$
     [0.,0., 0., 6., 5.]]

; Convert it to sparse storage format:
A = SPRSIN(A)

; Store it in the file sprs.as:
WRITE_SPR, A, 'sprs.as'
```

## Version History

Introduced: Pre 4.0

## See Also

FULSTR, LINBCG, SPRSAB, SPRSAX, SPRSIN, READ_SPR

# WRITE_SRF

The WRITE_SRF procedure writes an image and its color table vectors to a Sun Raster File (SRF).

WRITE_SRF only writes 32-, 24-, and 8-bit-deep rasterfiles of type RT_STANDARD. Use the UNIX command `rasfilter8to1` to convert these files to 1-bit deep files. See the file `/usr/include/rasterfile.h` for the structure of Sun rasterfiles.

This routine is written in the IDL language. Its source code can be found in the file `write_srf.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

WRITE_SRF, *Filename* [, *Image*, *R*, *G*, *B*] [, /ORDER] [, /WRITE_32]

## Arguments

### Filename

A scalar string containing the full pathname of the SRF to write.

### Image

The array to be written to the SRF. If *Image* has dimensions (3,*n*,*m*), a 24-bit SRF is written. If *Image* is omitted, the entire current graphics window is read into an array and written to the SRF file. *Image* should be of byte type, and in top to bottom scan line order.

### R, G, B

The Red, Green, and Blue color vectors to be written to the file. If *R*, *G*, *B* values are not provided, the last color table established using LOADCT is included. If no color table has been established, WRITE_SRF calls LOADCT to load the grayscale entry (table 0).

## Keywords

### ORDER

Set this keyword to write the image from the top down instead of from the bottom up. This setting is only necessary when writing a file from the current IDL graphics window; it is ignored when writing a file from a data array passed as a parameter.

### WRITE_32

Set this keyword to write a 32-bit file. If the input image is a TrueColor image, dimensioned (3, *n*, *m*), it is normally written as a 24-bit raster file.

## Examples

Create a pseudo screen dump from the current window:

```
WRITE_SRF, 'test.srf', TVRD()
```

## Version History

Introduced: Original

READ_SRF, QUERY_* Routines

# WRITE_SYLK

The WRITE_SYLK function writes the contents of an IDL variable to a SYLK (Symbolic Link) format spreadsheet data file.

**Note**

This routine writes only numeric and string SYLK data. It cannot handle spreadsheet and cell formatting information (cell width, text justification, font type, date, time, monetary notations, etc.). A given SYLK data file cannot be appended with data blocks through subsequent calls.

This routine is written in the IDL language. Its source code can be found in the file `write_sylk.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = WRITE_SYLK( *File*, *Data* [, STARTCOL=*column*] [, STARTROW=*row*] )

## Return Value

The function returns TRUE if the write operation was successful.

## Arguments

### File

A scalar string specifying the full path name of the SYLK file to write.

### Data

A scalar, vector, or 2D array to be written to *File*.

## Keywords

### STARTCOL

Set this keyword to the first column of spreadsheet cells to write. If not specified, the write operation begins with the first column found in the file (column 0).

### STARTROW

Set this keyword to the first row of spreadsheet cells to write. If not specified, the write operation begins with the first row of cells found in the file (row 0).

## Examples

Suppose you wish to write the contents of a 2 by 2 floating-point array, `data`, to a SYLK data file called “bar.slk” such that the matrix would appear with it’s upper left data at the cell in the 10th row and the 20th column. Use the following command:

```
status = WRITE_SYLK('bar.slk', data, STARTROW = 9, STARTCOL = 19)
```

The IDL variable `status` will contain the value 1 if the operation was successful.

## Version History

Introduced: 4.0

READ_SYLK

# WRITE_TIFF

The WRITE_TIFF procedure can write TIFF files with one or more channels, where each channel can contain 1, 4, 8, 16, or 32-bit integer pixels, or floating-point values.

## Syntax

WRITE_TIFF, *Filename [, Image]* [, /APPEND]
[, BITS_PER_SAMPLE={1 | 4 | 8}] [, RED=*value*] [, GREEN=*value*]
[, BLUE=*value*] [, COMPRESSION={0 | 2 | 3}] [, GEOTIFF=*structure*]
[, /LONG | , /SHORT | , /FLOAT] [, ORIENTATION=*value*]
[, PLANARCONFIG={1 | 2}] [, UNITS={1 | 2 | 3}] [, /VERBOSE]
[, XRESOL=*pixels/inch*] [, YRESOL=*pixels/inch*]

## Arguments

### Filename

A scalar string containing the full pathname of the TIFF to write.

### Image

The array to be written to the TIFF. If *Image* has dimensions (k,n,m), a k-channel TIFF is written. Image should be in top to bottom scan line order. By default, this array is converted to byte format before being written (see the LONG, SHORT and FLOAT keywords below). Note that many TIFF readers can read only one- or three-channel images.

**Note**

The Image argument is optional if PLANARCONFIG is set to 2 and the RED, GREEN, and BLUE keywords have been set to 2D arrays.

**Note**

Grayscale TIFF images are written out with the PhotometricInterpretation tag set to BlackIsZero, implying that values of 0 should correspond to black. If you want values of 0 to correspond to white, you should invert your pixel values before calling WRITE_TIFF.

### Order

*This argument is obsolete. The Order argument has been replaced by the ORIENTATION keyword. Code that uses the Order argument will continue to work as before, but new code should use the ORIENTATION keyword instead.*

## Keywords

### APPEND

Set this keyword to specify that the image should be added to the existing file, creating a multi-image TIFF file.

### BITS_PER_SAMPLE

Set this keyword to either 1, 4, or 8 to create a grayscale image file with the specified number of bits per pixel. For 1-bit (bi-level) images, an output pixel is assigned the value 1 (one) if the corresponding input pixel is nonzero. For 4-bit grayscale images, the input pixel values *must* be in the range 0 through 15, or the image will be garbled. The default is BITS_PER_SAMPLE=8. This keyword is ignored if an RGB image or color palette is present, or if one of the FLOAT, LONG, or SHORT keywords is set.

### COMPRESSION

Set this keyword to select the type of compression to be used:

- 0 = none (default)
- 2 = PackBits
- 3 = JPEG (ITIFF files)

**Note**

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and the ORIENTATION keyword should not be specified. If your input image is not in top-to-bottom order, you should use REVERSE(*image*, 2) to flip the order before calling WRITE_TIFF.

### FLOAT

Set this keyword to write the pixel components as floating-point entities (the default is 8-bit).

## GEOTIFF

Set this keyword to an anonymous structure containing one field for each of the GeoTIFF tags and keys to be written into the file. The GeoTIFF structure is formed using fields named from the following table.

| Anonymous Structure Field Name | IDLDatatype |
|---|---|
| **TAGS:** | |
| "MODELPIXELSCALETAG" | DOUBLE[3] |
| "MODELTRANSFORMATIONTAG" | DOUBLE[4,4] |
| "MODELTIEPOINTTAG" | DOUBLE[6,*] |
| **KEYS:** | |
| "GTMODELTYPEGEOKEY" | INT |
| "GTRASTERTYPEGEOKEY" | INT |
| "GTCITATIONGEOKEY" | STRING |
| "GEOGRAPHICTYPEGEOKEY" | INT |
| "GEOGCITATIONGEOKEY" | STRING |
| "GEOGGEODETICDATUMGEOKEY" | INT |
| "GEOGPRIMEMERIDIANGEOKEY" | INT |
| "GEOGLINEARUNITSGEOKEY" | INT |
| "GEOGLINEARUNITSIZEGEOKEY" | DOUBLE |
| "GEOGANGULARUNITSGEOKEY" | INT |
| "GEOGANGULARUNITSIZEGEOKEY" | DOUBLE |
| "GEOGELLIPSOIDGEOKEY" | INT |
| "GEOGSEMIMAJORAXISGEOKEY" | DOUBLE |
| "GEOGSEMIMINORAXISGEOKEY" | DOUBLE |
| "GEOGINVFLATTENINGGEOKEY" | DOUBLE |
| "GEOGAZIMUTHUNITSGEOKEY" | INT |

*Table 108: GEOTIFF Structures*

| Anonymous Structure Field Name | IDLDatatype |
|---|---|
| "GEOGPRIMEMERIDIANLONGGEOKEY" | DOUBLE |
| "PROJECTEDCSTYPEGEOKEY" | INT |
| "PCSCITATIONGEOKEY" | STRING |
| "PROJECTIONGEOKEY" | INT |
| "PROJCOORDTRANSGEOKEY" | INT |
| "PROJLINEARUNITSGEOKEY" | INT |
| "PROJLINEARUNITSIZEGEOKEY" | DOUBLE |
| "PROJSTDPARALLEL1GEOKEY" | DOUBLE |
| "PROJSTDPARALLEL2GEOKEY" | DOUBLE |
| "PROJNATORIGINLONGGEOKEY" | DOUBLE |
| "PROJNATORIGINLATGEOKEY" | DOUBLE |
| "PROJFALSEEASTINGGEOKEY" | DOUBLE |
| "PROJFALSENORTHINGGEOKEY" | DOUBLE |
| "PROJFALSEORIGINLONGGEOKEY" | DOUBLE |
| "PROJFALSEORIGINLATGEOKEY" | DOUBLE |
| "PROJFALSEORIGINEASTINGGEOKEY" | DOUBLE |
| "PROJFALSEORIGINNORTHINGGEOKEY" | DOUBLE |
| "PROJCENTERLONGGEOKEY" | DOUBLE |
| "PROJCENTERLATGEOKEY" | DOUBLE |
| "PROJCENTEREASTINGGEOKEY" | DOUBLE |
| "PROJCENTERNORTHINGGEOKEY" | DOUBLE |
| "PROJSCALEATNATORIGINGEOKEY" | DOUBLE |
| "PROJSCALEATCENTERGEOKEY" | DOUBLE |
| "PROJAZIMUTHANGLEGEOKEY" | DOUBLE |

*Table 108: GEOTIFF Structures (Continued)*

| Anonymous Structure Field Name | IDLDatatype |
|---|---|
| "PROJSTRAIGHTVERTPOLELONGGEOKEY" | DOUBLE |
| "VERTICALCSTYPEGEOKEY" | INT |
| "VERTICALCITATIONGEOKEY" | STRING |
| "VERTICALDATUMGEOKEY" | INT |
| "VERTICALUNITSGEOKEY" | INT |

*Table 108: GEOTIFF Structures (Continued)*

**Note**

If a GeoTIFF key appears multiple times in a file, only the value for the first instance of the key is returned.

## LONG

Set this keyword to write the pixel components as unsigned 32-bit entities (the default is 8-bit).

## ORIENTATION

Set this keyword to an integer value to specify the orientation of the TIFF image. The default is ORIENTATION=1.

**Note**

For COMPRESSION=3 (JPEG), all images are assumed to be in top-to-bottom order, and this keyword should not be specified.

Possible values are:

| Value | Description |
|---|---|
| 0 | Column 0 represents the left-hand side, and row 0 represents the bottom (same as 4) |
| 1 | Column 0 represents the left-hand side, and row 0 represents the top. |

*Table 109: ORIENTATION Keyword Values*

| Value | Description |
|---|---|
| 2 | Column 0 represents the right-hand side, and row 0 represents the top. |
| 3 | Column 0 represents the right-hand side, and row 0 represents the bottom. |
| 4 | Column 0 represents the left-hand side, and row 0 represents the bottom (same as 0) |
| 5 | Column 0 represents the top, and row 0 represents the left-hand side. |
| 6 | Column 0 represents the top, and row 0 represents the right-hand side. |
| 7 | Column 0 represents the bottom, and row 0 represents the right-hand side. |
| 8 | Column 0 represents the bottom, and row 0 represents the left-hand side. |

*Table 109: ORIENTATION Keyword Values (Continued)*

**Warning**

Not all TIFF readers honor the value of the ORIENTATION field. IDL writes the value into the file, but some readers are known to ignore this value. In such cases, we recommend that you convert the image to top-to-bottom order with the REVERSE function and then set ORIENTATION to 1.

## PLANARCONFIG

This keyword determines the order in which a multi-channel image is stored and written. It has no effect with a single-channel image. Set this keyword to 2 to if the Image parameter is interleaved by “plane”, or band, and its dimensions are (*Columns*, *Rows*, *Channels*). The default value is 1, indicating that multi-channel images are interleaved by color, also called channel, and its dimensions are (*Channels*, *Columns*, *Rows*).

As a special case, this keyword may be set to 2 to write an RGB image that is contained in three separate arrays (color planes), stored in the variables specified by the RED, GREEN, and BLUE keywords. Otherwise, omit this parameter (or set it to 1).

**Note**

Many TIFF readers can read only one- or three-channel images.

## RED, GREEN, BLUE

If you are writing a Palette color image, set these keywords equal to the color table vectors, scaled from 0 to 255.

If you are writing an RGB interleaved image (i.e., if the PLANARCONFIG keyword is set to 2), set these keywords to the names of the variables containing the three image components.

## SHORT

Set this keyword to write the pixel components as unsigned 16-bit entities (the default is 8-bit).

## UNITS

Set this keyword to one of the following values to specify the units used for the values specified by the XRESOL and YRESOL keywords:

| Value | Description |
|---|---|
| 1 | No units |
| 2 | Inches (the default) |
| 3 | Centimeters |

*Table 110: UNITS Keyword Values*

## VERBOSE

Set this keyword to produce additional diagnostic output during the write.

## XRESOL

Set this keyword to the horizontal resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of XRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

### YRESOL

Set this keyword to the vertical resolution, in pixels per unit, where the unit is specified by the value of the UNITS keyword (inches, by default). The default value of YRESOL is 100. Note that while this value is stored in the TIFF file, it may be interpreted by the TIFF reader in a variety of ways, or ignored.

## Examples

### Example 1

Create a pseudo screen dump from the current window. Note that this works only on a PseudoColor (8-bit) display:

```
WRITE_TIFF, 'test.tiff', TVRD()
```

### Example 2

Write a three-channel image from three one-channel (two-dimensional) arrays, contained in the variables Red, Green, and Blue:

```
WRITE_TIFF, 'test.tif', Red, Green, Blue, PLANARCONFIG=2
```

### Example 3

Write and read a multi-image TIFF file. The first image is a 16-bit single channel image stored using compression. The second image is an RGB image stored using 32-bits/channel uncompressed.

```
; Write the image data:
data = FIX(DIST(256))
rgbdata = LONARR(3,320,240)
WRITE_TIFF,'multi.tif',data,COMPRESSION=1,/SHORT
WRITE_TIFF,'multi.tif',rgbdata,/LONG,/APPEND
; Read the image data back
ok = QUERY_TIFF('multi.tif',s)
IF (ok) THEN BEGIN
   FOR i=0,s.NUM_IMAGES-1 DO BEGIN
      imp = QUERY_TIFF('multi.tif',t,IMAGE_INDEX=i)
      img = READ_TIFF('multi.tif',IMAGE_INDEX=i)
      HELP,t,/STRUCTURE
      HELP,img
   ENDFOR
ENDIF
```

## Version History

Introduced: 5.0

ITIFF support added: 5.6

## See Also

READ_TIFF, QUERY_* Routines

# WRITE_WAV

The WRITE_WAV procedure writes the audio stream to the named .WAV file.

## Syntax

WRITE_WAV, *Filename*, *Data*, *Rate*

## Arguments

### Filename

A scalar string containing the full pathname of the .WAV file to write.

### Data

The array to write into the new .WAV file. The array can be a one- or two-dimensional array. A two-dimensional array is written as a multi-channel audio stream where the leading dimension of the IDL array is the number of channels. If the input array is in BYTE format, the data is written as 8-bit samples, otherwise, the data is written as signed 16-bit samples.

### Rate

The sampling rate for the data array in samples per second.

## Keywords

None.

## Version History

Introduced: 5.3

# WRITE_WAVE

The WRITE_WAVE procedure writes a three dimensional IDL array to a `.wave` or `.bwave` file for use with the Wavefront Advanced Data Visualizer. Note that this routine only writes one scalar field for each Wavefront file that it creates.

This routine is written in the IDL language. Its source code can be found in the file `write_wave.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

WRITE_WAVE, *File*, *Array* [, /BIN] [, DATANAME=*string*] [, MESHNAME=*string*] [, /NOMESHDEF] [, /VECTOR]

## Arguments

### File

A scalar string containing the full path name of the Wavefront file to write.

### Array

A 3D array to be written to the file.

## Keywords

### BIN

Set this keyword to create a binary file. By default, text files are created.

### DATANAME

Set this keyword to the name of the data inside of the Wavefront file. If not specified, the name used is “idldata”.

### MESHNAME

Set this keyword to the name of the mesh used in the Wavefront file. If not specified, the name used is “idlmesh”.

### NOMESHDEF

Set this keyword to *omit* the mesh definition from the Wavefront file.

### VECTOR

Set this keyword to write the variable as a vector. The data is written as an array of 3-space vectors. The array may contain any number of dimensions but must have a leading dimension of 3. If the leading array dimension is not 3, this keyword is ignored.

## Version History

Introduced: Pre 4.0

## See Also

READ_WAVE

# WRITEU

The WRITEU procedure writes unformatted binary data from an expression into a file. This procedure performs a direct transfer with no processing of any kind being done to the data.

## Syntax

WRITEU, *Unit*, $Expr_1$ ..., $Expr_n$ [, TRANSFER_COUNT=*variable*]

## Arguments

### Unit

The IDL file unit to which the output is sent.

### $Expr_i$

The expressions to be output. For non-string variables, the number of bytes implied by the data type is output. When WRITEU is used with a variable of type string, IDL outputs exactly the number of bytes contained in the existing string.

## Keywords

### TRANSFER_COUNT

Set this keyword to a named variable in which to return the number of elements transferred by the output operation. Note that the number of elements is not the same as the number of bytes (except in the case where the data type being transferred is bytes). For example, transferring 256 floating-point numbers yields a transfer count of 256, not 1024 (the number of bytes transferred).

This keyword is useful with files opened with the RAWIO keyword to the OPEN routines. Normally, writing more data than an output device will accept causes an error. Files opened with the RAWIO keyword will not generate such an error. Instead, the programmer must keep track of the transfer count to judge the success or failure of a WRITEU operation.

### Obsolete Keywords

The following keywords are obsolete:

- REWRITE

For information on obsolete keywords, See Appendix I, “Obsolete Features”.

## Examples

```
; Create some data to store in a file:
D = BYTSCL(DIST(200))
; Open a new file for writing as IDL file unit number 1:
OPENW, 1, 'newfile'
; Write the data in D to the file:
WRITEU, 1, D
; Close file unit 1:
CLOSE, 1
```

## Version History

Introduced: Original

## See Also

OPEN, READU, Chapter 10, “Files and Input/Output” in the *Building IDL Applications* manual, and “Unformatted Input/Output with Structures” in Chapter 7 of the *Building IDL Applications* manual.

# WSET

The WSET procedure selects the current window. Most IDL graphics routines do not explicitly require the IDL window to be specified. Instead, they use the window known as the current window. The window index number of the current window is contained in the read-only system variable !D.WINDOW. WSET only works with devices that have windowing systems.

## Syntax

WSET [, *Window_Index*]

## Arguments

### Window_Index

This argument specifies the window index of the window to be made current. If this argument is not specified, a default of 0 is used.

If you set *Window_Index* equal to -1, IDL will try to locate an existing window to make current, ignoring any managed draw widgets that may exist. If there is no window to make current, WSET changes the value of the WINDOW field of the !D system variable to -1, indicating that there are no current windows.

If there are no existing IDL windows, and you call WSET without the *Window_Index* argument or with a *Window_Index* of 0, a new window with the index 0 is opened. Calling WSET with a *Window_Index* for a window that does not exist, except for window 0, results in a “Window is closed and unavailable” error message.

## Keywords

None.

## Examples

Create IDL windows 1 and 2 by entering:

```
WINDOW, 1 & WINDOW, 2
```

Set the current window to window 1 and display an image by entering:

```
WSET, 1 & TVSCL, DIST(100)
```

Set the current window to window 2 and display an image by entering:

```
WSET, 2 & TVSCL, DIST(100)
```

## Version History

Introduced: Original

## See Also

WDELETE, WINDOW, WSHOW

# WSHOW

The WSHOW procedure exposes or hides the designated window.

## Syntax

WSHOW [, *Window_Index* [, *Show*]] [, /ICONIC]

## Arguments

### Window_Index

The window index of the window to be hidden or exposed. If this argument is not specified, the current window is assumed. If this index is the window ID of a draw widget, the widget base associated with that drawable is brought to the front of the screen.

### Show

Set *Show* to 0 to hide the window. Omit this argument or set it to 1 to expose the window.

## Keywords

### ICONIC

Set this keyword to iconify the window. Set ICONIC to 0 to de-iconify the window.

Under windowing systems, iconification is the task of the window manager, and client applications such as IDL have no direct control over it. The ICONIC keyword serves as a hint to the window manager, which is free to iconify the window or ignore the request as it sees fit.

## Examples

To bring IDL window number 0 to the front, enter:

```
WSHOW, 0
```

## Version History

Introduced: Original

WDELETE, WINDOW, WSET

# WTN

The WTN function returns a multi-dimensional discrete wavelet transform of the input array A. The transform is based on a Daubechies wavelet filter.

WTN is based on the routine `wtn` described in section 13.10 of *Numerical Recipes in C: The Art of Scientific Computing* (Second Edition), published by Cambridge University Press, and is used by permission.

## Syntax

*Result* = WTN( *A*, *Coef* [, /COLUMN] [, /DOUBLE] [, /INVERSE] [, /OVERWRITE] )

Return Value

## Arguments

### A

The input vector or array. The dimensions of *A* must all be powers of 2.

### Coef

An integer that specifies the number of wavelet filter coefficients. The allowed values are 4, 12, or 20. When *Coef* is 4, the `daub4()` function (see *Numerical Recipes*, section 13.10) is used. When *Coef* is 12 or 20, `pwt()` is called, preceded by `pwtset()` (see *Numerical Recipes*, section 13.10).

## Keywords

### COLUMN

Set this keyword if the input array *A* is in column-major format (composed of column vectors) rather than in row-major format (composed of row vectors).

### DOUBLE

Set this keyword to force the computation to be done in double-precision arithmetic.

### INVERSE

If the INVERSE keyword is set, the inverse transform is computed. By default, WTN performs the forward wavelet transform.

### OVERWRITE

Set the OVERWRITE keyword to perform the transform “in place.” The result overwrites the original contents of the array.

## Examples

This example demonstrates the use of IDL’s discrete wavelet transform and sparse array storage format to compress and store an 8-bit gray-scale digital image. First, an image selected from the `people.dat` data file is transformed into its wavelet representation and written to a separate data file using the WRITEU procedure.

Next, the transformed image is converted, using the SPRSIN function, to row-indexed sparse storage format retaining only elements with an absolute magnitude greater than or equal to a specified threshold. The sparse image is written to a data file using the WRITE_SPR procedure.

Finally, the transformed image is reconstructed from the storage file and displayed alongside the original.

```
; Begin by choosing the number of wavelet coefficients to use and a
; threshold value:
coeffs = 12 & thres = 10.0

; Open the people.dat data file, read an image using associated
; variables, and close the file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])
images = assoc(1, bytarr(192, 192))
image_1 = images[0]
close, 1

; Expand the image to the nearest power of two using cubic
; convolution, and transform the image into its wavelet
; representation using the WTN function:
pwr = 256
image_1 = CONGRID(image_1, pwr, pwr, /CUBIC)
wtn_image = WTN(image_1, coeffs)

; Write the image to a file using the WRITEU procedure and check
; the size of the file (in bytes) using the FSTAT function:
OPENW, 1, 'original.dat'
WRITEU, 1, wtn_image
```

```
status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the file is ', status.size, ' bytes.'

; Now, we convert the wavelet representation of the image to a
; row-indexed sparse storage format using the SPRSIN function,
; write the data to a file using the WRITE_SPR procedure, and check
; the size of the "compressed" file:
sprs_image = SPRSIN(wtn_image, THRES = thres)
WRITE_SPR, sprs_image, 'sparse.dat'
OPENR, 1, 'sparse.dat'
status = FSTAT(1)
CLOSE, 1
PRINT, 'Size of the compressed file is ', status.size, ' bytes.'

; Determine the number of elements (as a percentage of total
; elements) whose absolute magnitude is less than the specified
; threshold. These elements are not retained in the row-indexed
; sparse storage format:
PRINT, 'Percentage of elements under threshold: ',$
   100.*N_ELEMENTS(WHERE(ABS(wtn_image) LT thres, $
   count)) / N_ELEMENTS(image_1)

; Next, read the row-indexed sparse data back from the file
; sparse.dat using the READ_SPR function and reconstruct the
; image from the non-zero data using the FULSTR function:
sprs_image = READ_SPR('sparse.dat')
wtn_image = FULSTR(sprs_image)

; Apply the inverse wavelet transform to the image:
image_2 = WTN(wtn_image, COEFFS, /INVERSE)

; Calculate and print the amount of data used in reconstruction of
; the image:
PRINT, 'The image on the right is reconstructed from:', $
   100.0 - (100.* count/N_ELEMENTS(image_1)),$
   '% of original image data.'

; Finally, display the original and reconstructed images side by
; side:
WINDOW, 1, XSIZE = pwr*2, YSIZE = pwr, $
   TITLE = 'Wavelet Image Compression and File I/O'
TV, image_1, 0, 0
TV, image_2, pwr - 1, 0
```

### IDL Output

```
Size of the file is   262144 bytes.
Size of the compressed file is   69600 bytes.
```

```
Percentage of elements under threshold:   87.0331
The image on the right is reconstructed from: 12.9669% of original
image data.
```

The sparse array contains only 13% of the elements contained in the original array. The following figure is created from this example. The image on the left is the original 256 by 256 image. The image on the right was compressed by the above process and was reconstructed from 13% of the original data. The size of the compressed image's data file is 26.6% of the size of the original image's data file. Note that due to limitations in the printing process, differences between the images may not be as evident as they would be on a high-resolution printer or monitor.

*Figure 31: Original image (left) and image reconstructed from 13% of the data (right).*

FFT

# WV_* Routines

For information, see the *Chapter 1, "Introduction to the IDL Wavelet Toolkit"* in the *IDL Wavelet Toolkit* manual.

# XBM_EDIT

The XBM_EDIT procedure is a utility for creating and editing icons for use with IDL widgets as bitmap labels for widget buttons.

The icons created with XBM_EDIT can be saved in two different file formats. IDL "array definition files" are text files that can be inserted into IDL programs. "Bitmap array files" are data files that can be read into IDL programs. Bitmap array files should be used temporarily until the final icon design is determined and then they can be saved as IDL array definitions for inclusion in the final widget code. This routine does not check the file types of the files being read and assumes that they are of the correct size and type for reading. XBM_EDIT maintains its state in a common block so it is restricted to one working copy at a time.

This routine is written in the IDL language. Its source code can be found in the file `xbm_edit.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XBM_EDIT [, /BLOCK] [, FILENAME=*string*] [, GROUP=*widget_id*] [, XSIZE=*pixels*] [, YSIZE=*pixels*]

## Arguments

None.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XBM_EDIT block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

### FILENAME

Set this keyword to a scalar string that contains the filename to be used for the new icon. If this argument is not specified, the name “idl.bm” is used. The filename can be changed in XBM_EDIT by editing the “Filename” field before selecting a file option.

### GROUP

The widget ID of the widget that calls XBM_EDIT. When this ID is specified, the death of the caller results in the death of XBM_EDIT.

### XSIZE

The number of pixels across the bitmap is in the horizontal direction. The default value is 16 pixels.

### YSIZE

The number of pixels across the bitmap is in the vertical direction. The default value is 16 pixels.

## Version History

Introduced: Pre 4.0

WIDGET_BUTTON

# XDISPLAYFILE

The XDISPLAYFILE procedure is a utility for displaying ASCII text files using a widget interface.

This routine is written in the IDL language. Its source code can be found in the file `xdisplayfile.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XDISPLAYFILE, *Filename* [, /BLOCK] [, DONE_BUTTON=*string*]
[, /EDITABLE] [, FONT=*string*] [, GROUP=*widget_id*] [, HEIGHT=*lines*]
[, /MODAL] [, TEXT=*string or string array*] [, TITLE=*string*]
[, WIDTH=*characters*] [, WTEXT=*variable*]

## Arguments

### Filename

A scalar string that contains the filename of the file to display. *Filename* can include a path to that file.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XDISPLAYFILE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

## DONE_BUTTON

Set this keyword to a string containing the text to use for the Done button label. If omitted, the text “Done with <filename>” is used.

## EDITABLE

Set this keyword to allow modifications to the text displayed in XDISPLAYFILE. Setting this keyword also adds a “Save” button in addition to the Done button.

## FONT

A string containing the name of the font to use. The font specified is a device font (an X Windows font on Motif systems; a TrueType or PostScript font on Windows systems). See “About Device Fonts” on page 3962 for details on specifying names for device fonts. If this keyword is omitted, the default font is used.

## GROUP

The widget ID of the widget that calls XDISPLAYFILE. If this keyword is specified, the death of the group leader results in the death of XDISPLAYFILE.

## HEIGHT

The number of text lines that the widget should display at one time. If this keyword is not specified, 24 lines is the default.

## MODAL

Set this keyword to create the XDISPLAYFILE dialog as a modal dialog. Setting the MODAL keyword allows you to call XDISPLAYFILE from another modal dialog.

## TEXT

A string or string array to be displayed in the widget instead of the contents of a file. If this keyword is present, the *Filename* input argument is ignored (but is still required). String arrays are displayed one element per line.

## TITLE

A string to use as the widget title rather than the file name or “XDisplayFile”.

## WIDTH

The width of the widget display in characters. If this keyword is not specified, 80 characters is the default.

### WTEXT

Set this keyword to a named variable that will contain the widget ID of the text widget. This allows setting text selections and cursor positions programmatically. For example, the following code opens the XDISPLAYFILE widget and selects the first 10 characters of the file displayed in the text widget:

```
XDISPLAYFILE, 'myfile.txt', /EDITABLE, WTEXT=w
WIDGET_CONTROL, w, SET_TEXT_SELECT=[0, 10]
```

## Version History

Introduced: Pre 4.0

# XDXF

The XDXF procedure is a utility for displaying and interactively manipulating DXF objects.

## Using XDXF

XDXF displays a resizeable top-level base with a menu and draw widget used to display and manipulate the orientation of a DXF object.

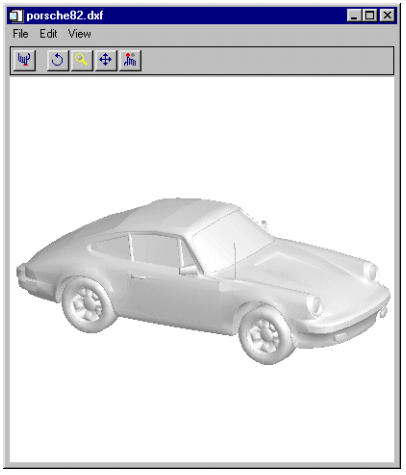

*Figure 32: The XDXF Utility*

XDXF also displays a dialog that contains block and layer information and allows the user to turn on and off the display of individual layers.

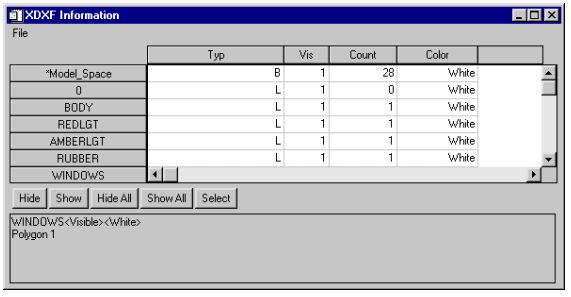

*Figure 33: The XDXF Information Dialog*

### The XDXF Toolbar

The XDXF toolbar contains the following buttons:

**Reset:** Resets rotation, scaling, and panning.

**Rotate:** Click the left mouse button on the object and drag to rotate.

**Pan:** Click the left mouse button on the object and drag to pan.

**Zoom:** Click the left mouse button on the object and drag to zoom in or out.

**Select:** Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

### The XDXF Information Dialog

The XDXF Information dialog displays information about the blocks and layers contained in the currently displayed object, and allows you to turn on and off the display of each layer.

To show or hide layers in the DXF object, select the layer from the list of layers on the left of the dialog, and click the **Show** or **Hide** button. Alternatively, you can click in the “Vis” field for the desired layer. To show or hide all layers, click the **Show All** or **Hide All** buttons.

If the **View Block Outlines** checkbox is selected, a green box will be displayed around the currently selected block, if any.

## Syntax

XDXF [, *Filename*] [, /BLOCK] [, GROUP=*widget_id*] [, SCALE=*value*] [, /TEST] [*keywords to XOBJVIEW*]

## Arguments

### Filename

A string specifying the name of the DXF file to display. If this argument is not specified, a file selection dialog is opened.

# Keywords

XDXF accepts the keywords to XOBJVIEW. (Note, however, that specifying the XOBJVIEW keyword MODAL is interpreted by XDXF as a call to the BLOCK keyword.) In addition, XDXF supports the following keywords:

## BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XDXF block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

## GROUP

The widget ID of the widget that calls XDXF. When this ID is specified, the death of the caller results in the death of XDXF.

## SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XDXF window, regardless of the object's orientation.

## TEST

If this keyword is set, the file `heart.dxf` in the IDL distribution is automatically opened in XDXF.

# Examples

Display the file `heart.dxf`, contained in the IDL distribution:

```
XDXF, FILEPATH('heart.dxf', $
   SUBDIR=['examples', 'data'])
```

## Version History

Introduced: 5.4

IDLffDXF

# XFONT

The XFONT function is a utility that creates a modal widget for selecting and viewing an X Windows font.

Calling XFONT resets the current X Windows font.

**Note**

This routine is only available on UNIX platforms.

This routine is written in the IDL language. Its source code can be found in the file `xfont.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

*Result* = XFONT( [, GROUP=*widget_id*] [, /PRESERVE_FONT_INFO] )

## Return Value

The function returns a string containing the name of the last selected font. If no font is selected, or the “Cancel” button is clicked, a null string is returned.

## Arguments

None.

## Keywords

### GROUP

The widget ID of the widget that calls XFONT. When this ID is specified, the death of the caller results in the death of XFONT.

### PRESERVE_FONT_INFO

Set this keyword to make XFONT save the server font directory in common blocks so that subsequent calls to XFONT start-up much faster. If this keyword is not set, the common block is cleaned.

## Version History

Introduced: Pre 4.0

EFONT, SHOWFONT

# XINTERANIMATE

The XINTERANIMATE procedure is a utility for displaying an animated sequence of images using off-screen pixmaps or memory buffers. The speed and direction of the display can be adjusted using the widget interface.

MPEG animation files can be created either programmatically using keywords to open and save a file, or interactively using the widget interface. Note that the MPEG standard does not allow movies with odd numbers of pixels to be created.

**Note**

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

**Note**

Only a single copy of XINTERANIMATE can run at a time. If you need to run multiple instances of the animation widget concurrently, use the CW_ANIMATE compound widget.

This routine is written in the IDL language. Its source code can be found in the file `xinteranimate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Using XINTERANIMATE

Displaying an animated series of images using XINTERANIMATE requires at least three calls to the routine: one to initialize the animation widget, one to load images, and one to display the images. When initialized using the SET keyword, XINTERANIMATE creates an approximately square pixmap or memory buffer, large enough to contain the requested number of frames of the requested size. Images are loaded using the IMAGE and FRAME keywords. Finally, images are displayed by copying them from the pixmap or memory buffer to the visible draw widget.

See CW_ANIMATE for a description of the widget interface controls used by XINTERANIMATE.

# Syntax

XINTERANIMATE [, *Rate*]

**Keywords for initialization:** [, SET=*[sizex, sizey, nframes]*] [, /BLOCK] [, /CYCLE] [, GROUP=*widget_id*] [, /MODAL] [, MPEG_BITRATE=*value*] [, MPEG_IFRAME_GAP=*integer value*] [, MPEG_MOTION_VEC_LENGTH={1 | 2 | 3}] [, /MPEG_OPEN, MPEG_FILENAME=*string*] [ MPEG_QUALITY=*value*{0 to 100}] [, /SHOWLOAD] [, /TRACK] [, TITLE=*string*]

**Keywords for loading images:** [, FRAME=*value*{0 to (*nframes*-1)}[, IMAGE=*value*]] [, /ORDER] [, WINDOW=*[window_num* [, *x0*, *y0*, *sx*, *sy*]*]*]

**Keywords for running animations:** [, /CLOSE] [, /KEEP_PIXMAPS] [, /MPEG_CLOSE] [, XOFFSET=*pixels*] [, YOFFSET=*pixels*]

# Arguments

## Rate

A value between 0 and 100 that represents the speed of the animation as a percentage of the maximum display rate. The fastest animation is with a value of 100 and the slowest is with a value of 0. The default animation rate is 100. The animation must be initialized using the SET keyword before calling XINTERANIMATE with a rate value.

# Keywords: Initialization

The following keywords are used to initialize the animation display. The SET keyword *must* be provided. Other keywords described in this section are optional; note that they work only when SET is specified.

## SET

Set this keyword to a three-element vector [*Sizex*, *Sizey*, *Nframes*] to initialize XINTERANIMATE. *Sizex* and *Sizey* represent the width and height of the images to be displayed, in pixels. *Nframes* is the number of frames in the animation sequence. Note that *Nframes* must be at least 2 frames.

## BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active

command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XINTERANIMATE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

## CYCLE

Normally, frames are displayed going either forward or backwards. If the CYCLE keyword is set, the animation reverses direction after the last frame in either direction is displayed.

## GROUP

Set this keyword to the widget ID of the widget that calls XINTERANIMATE. When GROUP is specified, the death of the calling widget results in the death of XINTERANIMATE.

## MODAL

Set this keyword to block processing of events from other widgets until the user quits XINTERANIMATE. A group leader must be specified (via the GROUP keyword) for the MODAL keyword to have any effect. By default, XINTERANIMATE does not block event processing.

## MPEG_BITRATE

Set this keyword to a double-precision value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

| MPEG Version | Range |
|---|---|
| MPEG 1 | 0.1 to 104857200.0 |
| MPEG 2 | 0.1 to 429496729200.0 |

*Table 111: BITRATE Value Range*

If you do not set this keyword, IDL computes the MPEG_BITRATE value based upon the value you have specified for the MPEG_QUALITY keyword.

**Note**

Only use the MPEG_BITRATE keyword if changing the MPEG_QUALITY keyword value does not produce the desired results. It is highly recommended to set the MPEG_BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

## MPEG_FILENAME

Set this keyword equal to a string specifying the name of the MPEG file. If no file name is specified, the default value (`idl.mpg`) is used.

## MPEG_IFRAME_GAP

Set this keyword to a positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

If you do not specify this keyword, IDL computes the MPEG_IFRAME_GAP value based upon the value you have specified for the MPEG_QUALITY keyword.

**Note**

Only use the MPEG_IFRAME_GAP keyword if changing the MPEG_QUALITY keyword value does not produce the desired results.

## MPEG_MOTION_VEC_LENGTH

Set this keyword to an integer value specifying the length of the motion vectors to be used to generate predictive frames. Valid values include:

- 1 = Small motion vectors.
- 2 = Medium motion vectors.
- 3 = Large motion vectors.

If you do not set this keyword, IDL computes the MPEG_MOTION_VEC_LENGTH value based upon the value you have specified for the MPEG_QUALITY keyword.

**Note**

Only use the MPEG_MOTION_VEC_LENGTH keyword if changing the MPEG_QUALITY value does not produce the desired results.

### MPEG_OPEN

Set this keyword to open an MPEG file.

### MPEG_QUALITY

Set this keyword to an integer value between 0 (low quality) and 100 (high quality) inclusive to specify the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

**Note**

Since MPEG uses JPEG (lossy) compression, the original picture quality can't be reproduced even when setting QUALITY to its highest setting.

### SHOWLOAD

Set this keyword to display each frame and update the frame slider as frames are loaded.

### TRACK

Set this keyword to cause the frame slider to track the current frame when the animation is in progress. The default is not to track.

### TITLE

Use this keyword to specify a string to be used as the title of the animation widget. If TITLE is not specified, the title is set to "XInterAnimate."

## Keywords: Loading Images

The following keywords are used to load images into the animation display. They have no effect when initializing or running animations.

### FRAME

Use this keyword to specify the frame number when loading frames. FRAME must be set to a number in the range 0 to *Nframes*-1.

### IMAGE

Use this keyword to specify a single image to be loaded at the animation position specified by the FRAME keyword. (FRAME *must* also be specified.)

### ORDER

Set this keyword to display images from the top down instead of the default bottom up.

### WINDOW

When this keyword is specified, an image is copied from an existing window to the animation pixmap or memory buffer. (When using some windowing systems, using this keyword is much faster than reading from the display and then calling XINTERANIMATE with a 2-D array.)

The value of this parameter is either an IDL window number (in which case the entire window is copied), or a vector containing the window index and the rectangular bounds of the area to be copied. For example:

```
WINDOW = [Window_Number, X0, Y0, Sx, Sy]
```

## Keywords: Running Animations

The following keywords are used when running the animation. They have no effect when initializing the animation or loading images.

### CLOSE

Set this keyword to delete the offscreen pixmaps or buffers and the animation widget itself. This also takes place automatically when the user presses the “Done With Animation” button or closes the window with the window manager.

### KEEP_PIXMAPS

If this keyword is set, XINTERANIMATE will not destroy the animation pixmaps or buffers when it is killed. Calling XINTERANIMATE again without going through the SET and LOAD steps will play the same animation without the overhead of creating the pixmaps.

### MPEG_CLOSE

Set this keyword to close and save the MPEG file. This keyword has no effect if MPEG_OPEN was not used during initialization.

### XOFFSET

Use this keyword to specify the horizontal offset, in pixels from the left of the frame, of the image in the destination window.

### YOFFSET

Use this keyword to specify the vertical offset, in pixels from the bottom of the frame, of the image in the destination window.

## Examples

Enter the following commands to open the file `ABNORM.DAT` (a series of images of a human heart) and animate the images it contains using XINTERANIMATE.

```
OPENR, unit, FILEPATH('abnorm.dat', SUBDIR=['examples','data']), $
   /GET_LUN
H = BYTARR(64, 64, 16)
READU, unit, H
CLOSE, unit

; Read the images into variable H:
H = REBIN(H, 128, 128, 16)

; Initialize XINTERANIMATE:
XINTERANIMATE, SET=[128, 128, 16], /SHOWLOAD

; Load the images into XINTERANIMATE:
FOR I=0,15 DO XINTERANIMATE, FRAME = I, IMAGE = H[*,*,I]

; Play the animation:
XINTERANIMATE, /KEEP_PIXMAPS
```

**Note**

Since the KEEP_PIXMAPS keyword was supplied, the same animation can be replayed (after the animation widget has been destroyed) with the single command `XINTERANIMATE`.

CW_ANIMATE

# XLOADCT

The XLOADCT procedure is a utility that provides a graphical widget interface to the LOADCT procedure. XLOADCT displays the current colortable and shows a list of available predefined color tables. Clicking on the name of a color table causes that color table to be loaded in true color decomposed visual. Many other options, such as Gamma correction, stretching, and transfer functions can also be applied to the colortable.

This routine is written in the IDL language. Its source code can be found in the file `xloadct.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XLOADCT [, /BLOCK] [, BOTTOM=*value*] [, FILE=*string*] [, GROUP=*widget_id*] [, /MODAL] [, NCOLORS=*value*] [, /SILENT]
[, UPDATECALLBACK=‘*procedure_name*’ [, UPDATECBDATA=*value*]]
[, /USE_CURENT]

## Arguments

None.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XLOADCT block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

## BOTTOM

The first color index to use. XLOADCT will use color indices from BOTTOM to BOTTOM+NCOLORS-1. The default is BOTTOM=0.

## FILE

Set this keyword to a string representing the name of the file to be used instead of the file `colors1.tbl` in the IDL directory.

## GROUP

The widget ID of the widget that calls XLOADCT. When this ID is specified, a death of the caller results in a death of XLOADCT.

## MODAL

Set this keyword to block processing of events from other widgets until the user quits XLOADCT. A group leader must be specified (via the GROUP keyword) for the MODAL keyword to have any effect. By default, XLOADCT does not block event processing.

## NCOLORS

The number of colors to use. Use color indices from 0 to the smaller of !D.TABLE_SIZE-1 and NCOLORS-1. The default is all available colors (!D.TABLE_SIZE).

## SILENT

Normally, no informational message is printed when a color map is loaded. If this keyword is set to zero, the message is printed.

## UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECBDATA keyword.

## UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any. If

the UPDATECBDATA keyword is not set the value accepted by the DATA keyword to the procedure specified by UPDATECALLBACK will be undefined.

### USE_CURRENT

Set this keyword to use the current color tables, regardless of the contents of the COLORS common block.

## Version History

Introduced: Pre 4.0

LOADCT, XPALETTE, TVLCT

# XMANAGER

The XMANAGER procedure provides the main event loop and management for widgets created using IDL. Calling XMANAGER "registers" a widget program with the XMANAGER event handler. XMANAGER takes control of event processing until all widgets have been destroyed.

Beginning with IDL version 5.0, IDL supports an *active command line* that allows the IDL command input line to continue accepting input while properly configured widget applications are running. See "A Note About Blocking in XMANAGER" on page 2417 for a more detailed explanation of the active command line.

This routine is written in the IDL language. Its source code can be found in the file `xmanager.pro` in the `lib` subdirectory of the IDL distribution.

**Warning**

Although this routine is written in the IDL language, it may change in the future in its internal implementation. For future upgradability, it is best not to modify or even worry about what this routine does internally.

## Syntax

XMANAGER [, *Name*, *ID*] [, /CATCH] [, CLEANUP=*string*]
[, EVENT_HANDLER='*procedure_name*'] [, GROUP_LEADER=*widget_id*]
[, /JUST_REG] [, /NO_BLOCK]

## Arguments

### Name

A string that contains the name of the routine that creates the widget (i.e., the name of the widget creation routine that is calling XMANAGER).

**Note**

The *Name* argument is stored in a COMMON block for use by the XREGISTERED routine. The stored name is case-sensitive.

### ID

The widget ID of the top-level base that is the root of the widget hierarchy being to be managed.

# Keywords

## BACKGROUND

*This keyword is obsolete and is included in XMANAGER for compatibility with existing code only. Its functionality has been replaced by the TIMER keyword to the WIDGET_CONTROL procedure.*

## CATCH

Set this keyword to cause XMANAGER to catch any errors, using the CATCH procedure, when dispatching widget events. If the CATCH keyword is set equal to zero, execution halts and IDL provides traceback information when an error is detected. This keyword is set by default (errors are caught and processing continues).

Do not specify either the *Name* or *ID* argument to XMANAGER when specifying the CATCH keyword (they are ignored). CATCH turns error catching on and off for *all* applications managed by XMANAGER. When CATCH is specified, XMANAGER changes its error-catching behavior and returns immediately, without taking any other action.

**Note**

Beginning with IDL version 5.0, the default behavior of XMANAGER is to catch errors and continue processing events. In versions of IDL prior to version 5.0, XMANAGER halted when an error was detected. This change in default behavior was necessary in order to allow multiple widget applications (all being managed by XMANAGER) to coexist peacefully. When CATCH is set equal to zero, (the old behavior), any error halts XMANAGER, and thus halts event processing for all running widget applications.

Note also that CATCH is only effective if XMANAGER is blocking to dispatch errors. If event dispatching for an active IDL command line is in use, the CATCH keyword has no effect.

The CATCH=0 setting (errors are not caught and processing halts in XMANAGER when an error is detected) is intended as a debugging aid. Finished programs should not set CATCH=0.

## CLEANUP

Set this keyword to a string that contains the name of the routine to be called when the widget program dies. If this keyword is not specified, the routine (if any) specified

for the program's top-level base by the KILL_NOTIFY keyword to WIDGET_BASE or WIDGET_CONTROL is used.

The routine specified by CLEANUP becomes the KILL_NOTIFY routine for the widget application, overriding any cleanup routines that have been set previously via the KILL_NOTIFY keyword to WIDGET_BASE or WIDGET_CONTROL.

**Note**

Specifying a routine for the widget application's top-level base via the KILL_NOTIFY keyword to WIDGET_CONTROL *after* the call to XMANAGER will override the value of the CLEANUP keyword.

The cleanup routine is called with the widget identifier as its only argument.

## EVENT_HANDLER

Set this keyword to a string that contains the name of a routine to be called when a widget event occurs in the widget program being registered. If this keyword is not supplied, XMANAGER will construct a default name by adding the "_event" suffix to the *Name* argument. See the example below for a more detailed explanation.

## GROUP_LEADER

The widget ID of the group leader for the widget being processed. When the leader dies either by the users actions or some other routine, all widgets that have that leader will also die.

For example, a widget that views a help file for a demo widget would have that demo widget as its leader. When the help widget is registered, it sets the keyword GROUP_LEADER to the widget ID of the demo widget. If the demo widget were destroyed, the help widget led by it would be killed by the XMANAGER.

## JUST_REG

Set this keyword to indicate that XMANAGER should just register the widget and return immediately. This keyword is useful if you want to register a group of related top-level widgets before beginning event processing and one or more of the registered widgets requests that XMANAGER block event processing. (Note that in this case a later call to XMANAGER without the JUST_REG keyword is necessary to begin blocking.)

(See "A Note About Blocking in XMANAGER" on page 2417 for further discussion of the active command line.)

**Warning**

JUST_REG is not the same as NO_BLOCK. See "JUST_REG vs. NO_BLOCK" on page 2417 for additional details.

## NO_BLOCK

Set this keyword to tell XMANAGER that the registering client does not require XMANAGER to block if active command line event processing is available. If active command line event processing is available *and* every current XMANAGER client specifies NO_BLOCK, then XMANAGER will not block and the user will have access to the command line while widget applications are running.

**Note**

NO_BLOCK is ignored by IDL Runtime. If a main procedure uses XMANAGER with the NO_BLOCK keyword set, IDL Runtime defers subsequent processing of the commands following the XMANAGER call until the widget associated with the call to XMANAGER is destroyed.

It is important to understand the result of making nested calls to XMANAGER. XMANAGER can only block event processing for one client at a time. In applications involving multiple calls to XMANAGER (either directly or via calls to other routines that call XMANAGER, such as XLOADCT), blocking occurs only for the outermost call to XMANAGER, unless XMANAGER is told not to block in that call. If an application contains two calls to XMANAGER, the second call cannot block unless the first call sets the NO_BLOCK keyword. If an application contains a call to XMANAGER, followed by a call to XLOADCT, XLOADCT will not block unless the NO_BLOCK keyword was set in the call to XMANAGER (and the BLOCK keyword to XLOADCT is set). Consider the following example:

```
PRO blocking_example_event, event
   ; The following call blocks only if the NO_BLOCK keyword to
   ; XMANAGER is set:
   XLOADCT, /BLOCK
END

PRO blocking_example
   base=WIDGET_BASE(/COLUMN)
   button1=WIDGET_BUTTON(base,VALUE='Run XLOADCT')
   WIDGET_CONTROL,base, /REALIZE
   XMANAGER,'blocking_example', base, /NO_BLOCK
END
```

If the NO_BLOCK keyword to XMANAGER was not set in the above example, XLOADCT would not block, even though the BLOCK keyword was set. Setting the

NO_BLOCK keyword to XMANAGER prevents XMANAGER from blocking, thereby allowing the subsequent call to XMANAGER (via XLOADCT) to block.

**Warning**

NO_BLOCK is not the same as JUST_REG. See "JUST_REG vs. NO_BLOCK" on page 2417 for additional details.

# A Note About Blocking in XMANAGER

By default, IDL widget application blocking is *enabled*. Unless you take the appropriate steps, widget applications will block all other processing from occurring in IDL. Keeping the following issues in mind when writing widget applications will give you the best chance to create applications that coexist with other applications and the IDL command line.

## Active Command Line

Beginning with IDL version 5.0, most versions of IDL's command-processing front-end are able to support an *active command line* while running properly constructed widget applications. What this means is that—provided the widget application is properly configured—the IDL command input line is available for input while a widget application is running and widget events are being processed.

There are currently 3 separate IDL command-processing front-end implementations:

- Microsoft Windows IDLDE
- Motif IDLDE (UNIX)
- UNIX plain tty

Note that widget applications must be well-behaved with respect to blocking widget event processing. Since in most cases XMANAGER is used to handle widget event processing, this means that in order for the command line to remain active, all widget applications must be run with the NO_BLOCK keyword to XMANAGER set. (Note that since NO_BLOCK is *not* the default, it is quite likely that some application will block.) If a single application runs in blocking mode, the command line will be inaccessible until the blocking application exits. When a blocking application exits, the IDL command line will once again become active.

## JUST_REG vs. NO_BLOCK

Although their names imply a similar function, the JUST_REG and NO_BLOCK keywords perform very different services. It is important to understand what they do and how they differ.

The JUST_REG keyword tells XMANAGER that it should simply register a client and then return immediately. The result is that the client becomes known to XMANAGER, and that future calls to XMANAGER will take this client into account. Therefore, JUST_REG only controls how the registering call to XMANAGER should behave. The client can still be registered as requiring XMANAGER to block by setting NO_BLOCK=0. In this case, *future* calls to XMANAGER will block.

**Note**

JUST_REG is useful in situations where you suspect blocking might occur—if the active command line is not supported and you wish to keep it active before beginning event processing, if no command line is available (as with IDL Runtime applications), or if blocking will be requested at a later time. If no blocking will occur or if the blocking behavior is useful, it is not necessary to use JUST_REG.

The NO_BLOCK keyword tells XMANAGER that the registered client does not require XMANAGER to block if the command-processing front-end is able to support active command line event processing. XMANAGER remembers this attribute of the client until the client exits, even after the call to XMANAGER that registered the client returns. NO_BLOCK is just a “vote” on how XMANAGER should behave—the final decision is made by XMANAGER by considering the NO_BLOCK attributes of *all* of its current clients as well as the ability of the command-processing front-end in use to support the active command line.

## Blocking vs. Non-blocking Applications

The issue of blocking in XMANAGER requires some explanation. IDL widget events are not processed until the WIDGET_EVENT function is called to handle them. Otherwise, they are queued by IDL indefinitely. Knowing how and when to call WIDGET_EVENT is the primary service provided by XMANAGER.

There are two ways blocking is typically handled:

1. The first call to XMANAGER processes events by calling WIDGET_EVENT as necessary until no managed widgets remain on the screen. This is referred to as “blocking” because XMANAGER does not return to the caller until it is done, and the IDL command line is not available.
2. XMANAGER does not block, and instead, the part of IDL that reads command input also watches for widget events and calls WIDGET_EVENT as necessary while also reading command input. This is referred to as “non-blocking” or “active command line” mode.

XMANAGER will block unless the following conditions are met:

- All registered widget applications have the NO_BLOCK keyword to XMANAGER set.
- No modal dialogs are displayed. (Modal dialogs always block until dismissed.)

In general, we suggest that new widget applications be written with XMANAGER blocking disabled (that is, with the NO_BLOCK keyword set), unless the widget application will be run on IDL Runtime.

**Note**

NO_BLOCK is ignored by IDL Runtime. If a main procedure uses XMANAGER with the NO_BLOCK keyword set, IDL Runtime defers subsequent processing of the commands following the XMANAGER call until the widget associated with the call to XMANAGER is destroyed.

Since a widget application that does block event processing for itself will block event processing for all other widget applications (and the IDL command line) as well, we suggest that older widget applications be upgraded to take advantage of the new, non-blocking behavior by adding the NO_BLOCK keyword to most calls to XMANAGER.

## Examples

The following code creates a widget named EXAMPLE that is just a base widget with a “Done” button and registers it with the XMANAGER. Widgets being registered with the XMANAGER must provide at least two routines. The first routine creates the widget and registers it with the manager and the second routine processes the events that occur within that widget. An example widget is supplied below that uses only two routines. A number of other “Simple Widget Examples”, can be viewed by entering WEXMASTER at the IDL prompt. These simple programs demonstrate many aspects of widget programming.

The following lines of code would be saved in a single file, named `example.pro`:

```
; Begin the event handler routine for the EXAMPLE widget:
PRO example_event, ev

; The uservalue is retrieved from a widget when an event occurs:
WIDGET_CONTROL, ev.id, GET_UVALUE = uv

; If the event occurred in the Done button, kill the widget
; example:
if (uv eq 'DONE') THEN WIDGET_CONTROL, ev.top, /DESTROY
```

```
; End of the event handler part:
END

; This is the routine that creates the widget and registers it with
; the XMANAGER:
PRO example

; Create the top-level base for the widget:
base = WIDGET_BASE(TITLE='Example')

; Create the Done button and set its uservalue to "DONE":
done = WIDGET_BUTTON(base, VALUE = 'Done', UVALUE = 'DONE')
; Realize the widget (i.e., display it on screen):
WIDGET_CONTROL, base, /REALIZE

; Register the widget with the XMANAGER, leaving the IDL command
; line active:
XMANAGER, 'example', base, /NO_BLOCK

; End of the widget creation part:
END
```

First the event handler routine is listed. The handler routine has the same name as the main routine with the characters "_event" added. If you would like to use another event handler name, you would need to pass its name to XMANAGER using the EVENT_HANDLER keyword.

Notice that the event routine is listed before the main routine. If you include both the event routine and the main routine in a single `.pro` file with the name of the main routine (a common practice), this is necessary to ensure that the event routine is compiled. If the event routine were placed after the main routine in the file, IDL would compile and execute the main routine — and the compiler would exit — before the event routine was compiled. Alternatively, you can save your event routine in its own file with its own name (which in the above example would be `example_event.pro`), and IDL will compile the routine when it is required.

Notice also the NO_BLOCK keyword to XMANAGER has been included. This allows IDL to continue processing events and accepting input at the command prompt while the `example` widget application is running.

## Version History

Introduced: Pre 4.0

XMTOOL, XREGISTERED, Chapter 26, “Creating Widget Applications” in the *Building IDL Applications* manual.

# XMNG_TMPL

The XMNG_TMPL procedure is a template for widgets that use the XMANAGER. Use this template instead of writing your widget applications from “scratch”. This template can be found in the file `xmng_tmpl.pro` in the `lib` subdirectory of the IDL distribution.

The documentation header should be altered to reflect the actual implementation of the XMNG_TMPL widget. Use a global search and replace to replace the word `XMNG_TMPL` with the name of the routine you would like to use. All the comments with a “`***`” in front of them should be read, decided upon and removed from the final copy of your new widget routine.

## Syntax

XMNG_TMPL [, /BLOCK] [, GROUP=*widget_id*]

## Arguments

None.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XMNG_TMPL block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

### GROUP

The widget ID of the widget that calls XMNG_TMPL. When this ID is specified, the death of the caller results in the death of XMNG_TMPL.

## Version History

Introduced: Pre 4.0

## See Also

CW_TMPL

# XMTOOL

The XMTOOL procedure displays a tool for viewing widgets currently being managed by the XMANAGER. Only one instance of the XMTOOL can run at one time.

This routine is written in the IDL language. Its source code can be found in the file `xmtool.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XMTOOL [, /BLOCK] [, GROUP=*widget_id*]

## Arguments

None.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XMTOOL block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

### GROUP

The widget ID of the widget that calls XMTOOL. If the calling widget is destroyed, the XMTOOL is also destroyed.

## Version History

Introduced: Pre 4.0

XMANAGER

# XOBJVIEW

The XOBJVIEW procedure is a utility used to quickly and easily view and manipulate IDL Object Graphics on screen. It displays given objects in an IDL widget with toolbar buttons and menus providing functionality for manipulating, printing, and exporting the resulting graphic. The mouse can be used to rotate, scale, or translate the overall model shown in a view, or to select graphic objects in a view.

This routine is written in the IDL language. Its source code can be found in the file `xobjview.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Using XOBJVIEW

XOBJVIEW displays a resizeable top-level base with a menu, toolbar and draw widget, as shown in the following figure:

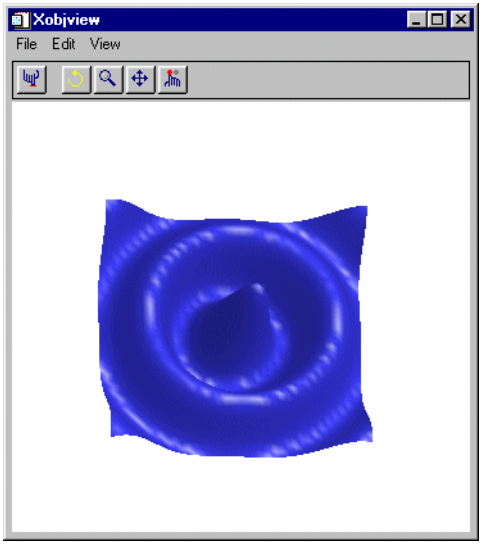

*Figure 34: The XOBJVIEW widget*

## The XOBJVIEW Toolbar

The XOBJVIEW toolbar contains the following buttons:

**Reset:** Resets rotation, scaling, and panning.

**Rotate:** Click the left mouse button on the object and drag to rotate.

**Pan:** Click the left mouse button on the object and drag to pan.

**Zoom:** Click the left mouse button on the object and drag to zoom in or out.

**Select:** Click on the object. The name of the selected object is displayed, if the object has a name, otherwise its class is displayed.

# Syntax

XOBJVIEW, *Obj* [, BACKGROUND=*[r, g, b]*] [, /BLOCK] [, /DOUBLE_VIEW ] [, GROUP=*widget_id*] [, /JUST_REG] [, /MODAL] [, REFRESH=*widget_id*] [, RENDERER={0 | 1}] [, SCALE=*value*] [, STATIONARY=*objref(s)*] [, /TEST] [, TITLE=*string*] [, TLB=*variable*] [, XOFFSET=*value*] [, XSIZE=*pixels*] [, YOFFSET=*value*] [, YSIZE=*pixels*]

# Arguments

## Obj

A reference to an atomic graphics object, an IDLgrModel, or an array of such references. If *Obj* is an array, the array can contain a mixture of such references. Also, if *Obj* is an array, all object references in the array must be unique (i.e. no two references in the array can refer to the same object).

*Obj* is not destroyed when XOBJVIEW is quit or killed.

# Keywords

## BACKGROUND

Set this keyword to a three-element [r, g, b] color vector specifying the background color of the XOBJVIEW window.

## BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes

all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XOBJVIEW block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

## DOUBLE_VIEW

Set this keyword to cause XOBJVIEW to set the DOUBLE property on the IDLgrView that it uses to display graphical data.

## GROUP

The widget ID of the widget that calls XOBJVIEW. When this ID is specified, the death of the caller results in the death of XOBJVIEW.

## JUST_REG

Set this keyword to indicate that the XOBJVIEW utility should just be registered and return immediately. This is useful if you want to register XOBJVIEW before beginning event processing and one or more widgets requests that XMANAGER block event processing.

**Note**

If your application will be distributed for use with an IDL Runtime license, and it allows users to control the contents of an XOBJVIEW window via a separate interface registered with XMANAGER, you must set the JUST_REG keyword. See "JUST_REG vs. NO_BLOCK" on page 2417 for additional details.

## MODAL

Set this keyword to block processing of events from other widgets until the user quits XOBJVIEW. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XOBJVIEW fabricates an invisible group leader for you.

**Note**

To be modal, XOBJVIEW does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures

were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See “Iconizing, Layering, and Destroying Groups of Top-Level Bases” on page 2128 for more information.)

To provide a simple means of invoking XOBJVIEW as a modal widget in applications that contain no other widgets, XOBJVIEW can be invoked as MODAL without specifying a group leader, in which case XOBJVIEW fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XOBJVIEW, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

## REFRESH

Set this keyword to the widget ID of the XOBJVIEW instance to be refreshed. To retrieve the widget ID of an instance of XOBJVIEW, first call XOBJVIEW with the TLB keyword. To refresh that instance of XOBJVIEW, call XOBVIEW again and set REFRESH to the value retrieved by the TLB keyword in the earlier call to XOBJVIEW. For example, in the initial call to XOBJVIEW, use the TLB keyword as follows:

```
XOBJVIEW, myobj, TLB=tlb
```

If the properties of `myobj` are changed in your application or at the IDL command line, refresh the view in XOBJVIEW by calling XOBJVIEW again with the REFRESH keyword:

```
XOBJVIEW, REFRESH=tlb
```

For an example application demonstrating the use of the REFRESH keyword, see “Example 3” on page 2433.

**Note**

Currently, the REFRESH keyword can only be used to refresh the object itself. All other keywords and arguments to XOBJVIEW are ignored when REFRESH is specified, therefore, properties such as the background color and scale are not affected.

## RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects in the XOBJVIEW draw window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See "Hardware vs. Software Rendering" in Chapter 34 of the *Using IDL* manual for details. Your choice of renderer may also affect the maximum size of the XOBJVIEW draw window. See "IDLgrWindow" on page 3705 for details.

## SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the object, while ensuring that no portion of the object will be clipped by the XOBJVIEW window, regardless of the object's orientation.

## STATIONARY

Set this keyword to a reference to an atomic graphics object, an IDLgrModel, or an array of such references. If this keyword is an array, the array can contain a mixture of such references. Also, if this keyword is an array, all object references in the array must be unique (i.e., no two references in the array can refer to the same object). Objects passed to XOBJVIEW via this keyword will not scale, rotate, or translate in response to mouse events. Default stationary objects are two lights. These two lights are replaced if one or more lights are supplied via this keyword. Objects specified via this keyword are not destroyed by XOBJVIEW when XOBJVIEW is quit or killed.

For example, to change the default lights used by XOBJVIEW, you could specify your own lights using the STATIONARY keyword as follows:

```
mylight1 = OBJ_NEW('IDLgrLight', TYPE=0, $
   COLOR=[255,0,0]) ; Ambient red
mylight2 = OBJ_NEW('IDLgrLight', TYPE=2, $
   COLOR=[255,0,0], LOCATION=[2,2,5]) ; Directional red

mymodel = OBJ_NEW('IDLgrModel')
mymodel -> Add, mylight1
mymodel -> Add, mylight2

XOBJVIEW, /TEST, STATIONARY=mymodel
```

## TLB

Set this keyword to a named variable that upon return will contain the widget ID of the top level base.

## TEST

If set, the *Obj* argument is not required (and is ignored if provided). A blue sinusoidal surface is displayed. This allows you to test code that uses XOBJVIEW without having to create an object to display.

## TITLE

Set this keyword to the string that appears in the XOBJVIEW title bar.

## XOFFSET

The horizontal offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## XSIZE

Set this keyword to the width of the drawable area in pixels. The default is 400.

## YOFFSET

The vertical offset of the widget in units specified by the UNITS keyword (pixels are the default) relative to its parent. This offset is specified relative to the upper left corner of the parent widget.

Specifying an offset relative to a row-major or column-major base widget does not work because those widgets enforce their own layout policies. This keyword is primarily of use relative to a plain base widget. Note that it is best to avoid using this style of widget layout.

## YSIZE

Set this keyword to the height of the drawable area in pixels. The default is 400.

# Examples

## Example 1

This example displays a simple IDLgrSurface object using XOBJVIEW:

```
oSurf = OBJ_NEW('IDLgrSURFACE', DIST(20))
XOBJVIEW, oSurf
```

## Example 2

This example displays an IDLgrModel object consisting of two separate objects:

```
; Create contour object:
oCont = OBJ_NEW('IDLgrContour', DIST(20), N_LEVELS=10)

; Create surface object:
oSurf = OBJ_NEW('IDLgrSurface', $
   DIST(20),INDGEN(20)+20, INDGEN(20)+20)

; Create model object:
oModel = OBJ_NEW('IDLgrModel')

; Add contour and surface objects to model:
oModel->Add, oCont
oModel->Add, oSurf

; View model:
XOBJVIEW, oModel
```

This code results in the following view in the XOBJVIEW widget:

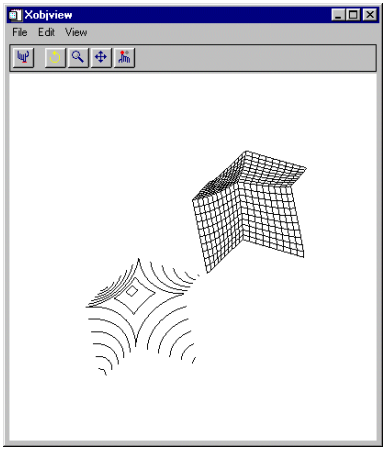

*Figure 35: Using XOBJVIEW to view a model consisting of two objects*

Note that when you click the Select button, and then click on an object, the class of that object appears next to the Select button. If the selected object has a non-null NAME property associated with it, that string value will be displayed, otherwise the name of the selected object's class will be displayed.

If you want the class of the model to appear when you click over any object in the model, you can set the SELECT_TARGET property of the model as follows:

```
oModel->SetProperty, /SELECT_TARGET
```

Also note that it is not necessary to create a model to view more than one object using XOBJVIEW. We could view the oCont and oSurf objects created in the above example by placing them in an array as follows:

```
XOBJVIEW, [oCont, oSurf]
```

## Example 3

This example demonstrates how the REFRESH keyword can be used to refresh the object displayed in an instance of XOBJVIEW.

```
PRO xobjview_refresh_event, event
   WIDGET_CONTROL, event.id, GET_UVALUE=uval
   WIDGET_CONTROL, event.top, GET_UVALUE=state
```

```
   CASE uval OF
      'red': BEGIN
          WIDGET_CONTROL, event.id, GET_VALUE=val
          state.myobj -> GetProperty, COLOR=c
          state.myobj -> SetProperty, COLOR=[val,c[1],c[2]]
          XOBJVIEW, REFRESH=state.tlb
          END
      'green':  BEGIN
          WIDGET_CONTROL, event.id, GET_VALUE=val
          state.myobj -> GetProperty, COLOR=c
          state.myobj -> SetProperty, COLOR=[c[0],val,c[2]]
          XOBJVIEW, REFRESH=state.tlb
          END
      'blue': BEGIN
          WIDGET_CONTROL, event.id, GET_VALUE=val
          state.myobj -> GetProperty, COLOR=c
          state.myobj -> SetProperty, COLOR=[c[0],c[1],val]
          XOBJVIEW, REFRESH=state.tlb
          END
   ENDCASE
END

PRO xobjview_refresh_cleanup, wID
   WIDGET_CONTROL, wID, GET_UVALUE=state
   OBJ_DESTROY, state.myobj
END

PRO xobjview_refresh
   base = WIDGET_BASE(/COLUMN, TITLE='Adjust Object Color', $
      XOFFSET=420, XSIZE=200)

   myobj = OBJ_NEW('IDLgrSurface', $
      BESELJ(SHIFT(DIST(40), 20, 20) / 2,0) * 20, $
      COLOR=[255, 60, 60], STYLE=2, SHADING=1)
   XOBJVIEW, myobj, TLB=tlb, GROUP=base, BACKGROUND=[0,0,0]

   red = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, TITLE='Red', $
      UVALUE='red', VALUE=255)
   green = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
      TITLE='Green', UVALUE='green', VALUE=60)
   blue = WIDGET_SLIDER(base, /DRAG, MIN=0, MAX=255, $
      TITLE='Blue', UVALUE='blue', VALUE=60)

   WIDGET_CONTROL, base, /REALIZE

   state = {myobj:myobj, tlb:tlb}
   WIDGET_CONTROL, base, SET_UVALUE=state
```

```
      XMANAGER, 'xobjview_refresh', base, /NO_BLOCK, $
         CLEANUP='xobjview_refresh_cleanup'
END
```

## Version History

Introduced: 5.3

XOBJVIEW_ROTATE, XOBJVIEW_WRITE_IMAGE

# XOBJVIEW_ROTATE

The XOBJVIEW_ROTATE procedure is used to programmatically rotate the object currently displayed in XOBJVIEW. XOBJVIEW must be called prior to calling XOBJVIEW_ROTATE. This procedure can be used to create animations of object displays.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_rotate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XOBJVIEW_ROTATE, *Axis*, *Angle* [, /PREMULTIPLY]

## Arguments

### Axis

A 3-element vector of the form [*x*, *y*, *z*] describing the axis about which the model is to be rotated.

### Angle

The amount of rotation, measured in degrees.

## Keywords

### PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

## Examples

The following example creates an animation of the test object (a surface) currently displayed in XOBJVIEW. It does this by rotating the surface through 360 degrees in increments of 10 degrees using XOBJVIEW_ROTATE, and writing the display image to a BMP file for each increment using XOBJVIEW_WRITE_IMAGE.

```
PRO RotateAndWriteObject

XOBJVIEW, /TEST
FOR i = 0, 359 DO BEGIN
   XOBJVIEW_ROTATE, [0, 1, 0], 1, /PREMULTIPLY;
   XOBJVIEW_WRITE_IMAGE, 'img' + $
   STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
ENDFOR

END
```

## Version History

Introduced: 5.5

XOBJVIEW, XOBJVIEW_WRITE_IMAGE

# XOBJVIEW_WRITE_IMAGE

The XOBJVIEW_WRITE_IMAGE procedure is used to write the object currently displayed in XOBJVIEW to an image file with the specified name and file format. XOBJVIEW must be called prior to calling XOBJVIEW_WRITE_IMAGE.

This routine is written in the IDL language. Its source code can be found in the file `xobjview_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XOBJVIEW_WRITE_IMAGE, *Filename*, *Format* [, DIMENSIONS=*[x, y]* ]

## Arguments

### Filename

A scalar string containing the name of the file to write.

### Format

A scalar string containing the name of the file format to write. See WRITE_IMAGE for a list of supported formats.

## Keywords

### DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current XOBJVIEW draw widget.

## Examples

See XOBJVIEW_ROTATE.

## Version History

Introduced: 5.5

## See Also

XOBJVIEW, XOBJVIEW_ROTATE

# XPALETTE

The XPALETTE procedure is a utility that displays a widget interface that allows interactive creation and modification of colortables using the RGB, CMY, HSV, or HLS color systems. Single colors can be defined or multiple color indices between two endpoints can be interpolated.

This routine is written in the IDL language. Its source code can be found in the file `xpalette.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Using the XPALETTE Interface

Calling XPALETTE causes a graphical interface to appear. The elements of this interface are described below.

### Plots on Left Side of Interface

Three plots show the current red, green, and blue vectors.

### Status Region

The center of the XPALETTE widget is a status region containing:

- The total number of colors.
- The current color index. XPALETTE allows changing one color at a time. This color is known as the “current color” and is indicated in the color spectrum display with a special marker.
- The current mark index. The mark is used to remember a color index. Click the “Set Mark Button” to make the current color index the mark index.
- A sample of the current color. The special marker used in the color spectrum display prevents the user from seeing the color of the current index, but it is visible here.

### Control Panel

A panel of 8 buttons control common XPALETTE functions:

- **Done:** Click this button to exit XPALETTE. The new color tables are saved in the COLORS common block and loaded to the display.
- **Predefined:** Click this button to start XLOADCT, allowing selection of one of the predefined color tables. Note that when you change the color map via XLOADCT, XPALETTE is not always able to keep its display accurate. This problem can be overcome by pressing the XPALETTE “Redraw” button after changing the colortable via XLOADCT.

- **Help:** Click this button to display help information.
- **Redraw:** Click this button to redraws the display using the current state of the color map.
- **Set Mark:** Click this button to set the value of the mark index to the current color index.
- **Switch Mark:** Click this button to exchange the mark and the current index.
- **Copy Current:** Click this button to make every color lying between the current index and the mark index (inclusive) the same color as the current color.
- **Interpolate:** Click this button to smoothly interpolate colors between the current index and the mark index.

### Color System Control

This section of the interface allows you to select the color system used to modify individual colors. The “Select Color System” pulldown menu lets you select from four different systems—RGB, CMY, HSV, and HLS. Depending upon the current system, 3 sliders below the pulldown menu allow you to alter the current color.

### Right Side Color Spectrum Display

A display on the right side of the XPALETTE interface shows the current color map as a series of squares. Color index 0 is at the upper left. The color index increases monotonically by rows going left to right and top to bottom. The current color index is indicated by a special marker symbol. There are 4 ways to change the current color:

- Click on any square in the color map display.
- Use the “By Index” slider to move to the desired color index.
- Use the “Row” Slider to move the marker vertically.
- Use the “Column” Slider to move the marker horizontally.

## A Note about the Colors Used in the Interface

XPALETTE uses two colors from the current color table as drawing foreground and background colors. These are used for the RGB plots on the left, and the current index marker on the right. This means that if the user set these two colors to the same value, the XPALETTE display could become unreadable (like writing on black paper with black ink). XPALETTE minimizes this possibility by noting changes to the color map and always using the brightest available color for the foreground color and the darkest for the background. Thus, the only way to make XPALETTE’s display

unreadable is to set the entire color map to a single color, which is highly unlikely. The only side effect of this policy is that you may notice XPALETTE redrawing the entire display after you've modified the current color. This simply means that the change has made XPALETTE pick new drawing colors.

# Syntax

XPALETTE [, /BLOCK] [, GROUP=*widget_id*]
[, UPDATECALLBACK='*procedure_name*' [, UPDATECBDATA=*value*]]

# Arguments

None.

# Keywords

## BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XPALETTE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

## GROUP

The widget ID of the widget that calls XPALETTE. When this ID is specified, a death of the caller results in a death of XPALETTE.

## UPDATECALLBACK

Set this keyword to a string containing the name of a user-supplied procedure that will be called when the color table is updated by XLOADCT. The procedure may optionally accept a keyword called DATA, which will be automatically set to the value specified by the optional UPDATECBDATA keyword.

### UPDATECBDATA

Set this keyword to a value of any type. It will be passed via the DATA keyword to the user-supplied procedure specified via the UPDATECALLBACK keyword, if any. If the UPDATECBDATA keyword is not set the value accepted by the DATA keyword to the procedure specified by UPDATECALLBACK will be undefined.

## Version History

Introduced: Pre 4.0

LOADCT, MODIFYCT, XLOADCT, TVLCT

# XPCOLOR

The XPCOLOR procedure is a utility that allows you to adjust the value of the current plotting color (foreground) using sliders, and store the desired color in the global system variable, !P.COLOR.

When XPCOLOR is called from the IDL input command line, the **Set Plot Color** dialog box appears. The dialog has two buttons (**Done** and **Help**) a single color swatch window, three sliders, and a pulldown menu with the four color systems: red, green, blue (RGB); cyan, magenta, yellow (CMY); hue, saturation, value (HSV); and hue, lightness, and saturation (HLS).

When you have chosen the color system and adjusted the sliders to your liking, click **Done** to store the color selected in the !P.COLOR system variable. Any plots generated in IDL afterwards use the color selected as the plotting (foreground) color until !P.COLOR is changed again.

**Note**

For a more flexible color editor, use the XPALETTE User Library routine.

This routine is written in the IDL language. Its source code can be found in the file `xpcolor.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XPCOLOR [, GROUP=*widget_id* ]

## Arguments

None.

## Keywords

### GROUP

Set this keyword to the group leader widget ID as passed to XMANAGER.

## Version History

Introduced: 4.0

# XPLOT3D

The XPLOT3D procedure is a utility for creating and interactively manipulating 3-D plots.

This routine is written in the IDL language. Its source code can be found in the file `xplot3d.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Using XPLOT3D

XPLOT3D displays a resizeable top-level base with a menu, toolbar and draw widget, as shown in the following figure:

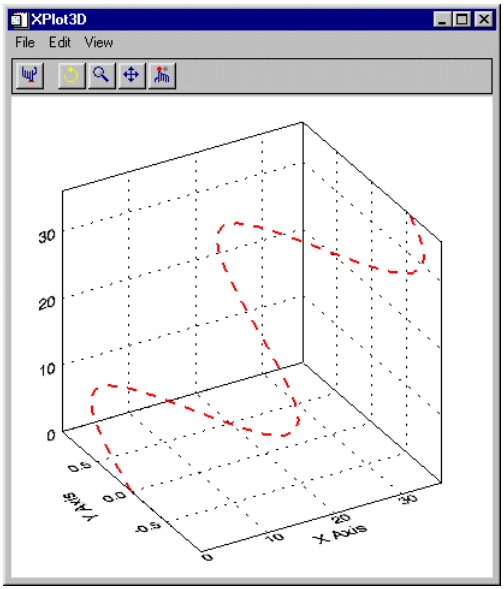

*Figure 36: The XPLOT3D Utility*

### The XPLOT3D Toolbar

The XPLOT3D toolbar contains the following buttons:

**Reset:** Resets rotation, scaling, and panning.

**Rotate:** Click the left mouse button on the plot and drag to rotate.

**Zoom:** Click the left mouse button on the plot and drag to zoom in or out.

**Pan:** Click the left mouse button on the plot and drag to pan.

**Select:** Click on a curve to display the curve name (if defined with the NAME keyword) on the XPLOT3D toolbar. If no name was defined for the curve, “IDLGRPOLYLINE” is displayed.

### Projecting Data onto Plot “Walls”

To turn on or off the projection of data onto the walls of the box enclosing the 3-D plot, select **All On**, **All Off**, **XY**, **YZ**, or **XZ** from the **View** → **2D Projection** menu.

### Changing the Axis Type

The **View** → **Axes** menu allows you to select one of the following types of axes:

- Simple Axes — displays the X, Y, and Z axes as lines.
- Box Axes — displays the X, Y, and Z axes as planes.
- No Axes — turns off the display of axes.

## Syntax

XPLOT3D, *X*, *Y*, *Z* [, /BLOCK] [, COLOR=*[r,g,b]*] [, /DOUBLE_VIEW]
[, GROUP=*widget_id*] [, LINESTYLE={0 | 1 | 2 | 3 | 4 | 5 | 6}] [, /MODAL]
[, NAME=*string*] [, /OVERPLOT] [, SYMBOL=*objref(s)*] [, /TEST]
[, THICK=*points*{1.0 to 10.0}] [, TITLE=*string*] [, XRANGE=*[min, max]*]
[, YRANGE=*[min, max]*] [, ZRANGE=*[min, max]*] [, XTITLE=*string*]
[, YTITLE=*string*] [, ZTITLE=*string*]

## Arguments

### X

A vector of X data values.

### Y

A vector of Y data values.

### Z

A vector of Z data values.

# Keywords

## BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XPLOT3D block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

## COLOR

Set this keyword to an [*r*, *g*, *b*] triplet specifying the color of the curve.

## DOUBLE_VIEW

Set this keyword to cause XPLOT3D to set the DOUBLE property on the IDLgrView that it uses to display the plot.

## GROUP

Set this keyword to the widget ID of the widget that calls XPLOT3D. When this keyword is specified, the death of the caller results in the death of XPLOT3D.

## LINESTYLE

Set this keyword to a value indicating the line style that should be used to draw the curve. The value can be either an integer value specifying a pre-defined line style, or a 2-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE keyword to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot

- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where repeat indicates the number of times consecutive runs of 1s or 0s in the bitmask should be repeated. (That is, if three consecutive 0s appear in the bitmask and the value of repeat is 2, then the line that is drawn will have six consecutive bits turned off.) The value of repeat must be in the range $1 \leq \text{repeat} \leq 255$.

The bitmask indicates which pixels are drawn and which are not along the length of the line. The bitmask is most conveniently specified as a 16-bit hexadecimal value.

For example, LINESTYLE = [2, 'F0F0'X] describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

## MODAL

Set this keyword to block processing of events from other widgets until the user quits XPLOT3D. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XPLOT3D fabricates an invisible group leader for you.

**Note**

To be modal, XPLOT3D does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See “Iconizing, Layering, and Destroying Groups of Top-Level Bases” on page 2128 for more information.)

To provide a simple means of invoking XPLOT3D as a modal widget in applications that contain no other widgets, XPLOT3D can be invoked as MODAL without specifying a group leader, in which case XPLOT3D fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XPLOT3D, /MODAL. As with other IDL widget procedures with names prefixed with “X”, specify the group leader via the GROUP keyword.

## NAME

Set this keyword to a string specifying the name for the data curve being plotted. The name is displayed on the XPLOT3D toolbar when the curve is selected with the

mouse. (To select the curve with the mouse, XPLOT3D must be in select mode. You can put XPLOT3D in select mode by clicking on the rightmost button on the XPLOT3D toolbar.)

## OVERPLOT

Set this keyword to draw the curve in the most recently created view. The TITLE, [XYZ]TITLE, [XYZ]RANGE, and MODAL keywords are ignored if this keyword is set.

## SYMBOL

Set this keyword to a vector containing one or more instances of the IDLgrSymbol object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set SYMBOL to a scalar.

## TEST

If set, the *X*, *Y*, and *Z* arguments are not required (and are ignored if provided). A sinusoidal curve is displayed instead. This allows you to test code that uses XPLOT3D without having to specify plot data.

## THICK

Set this keyword to a value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. The default is 1.0 points.

## TITLE

Set this keyword to a string to appear in the XPLOT3D title bar.

## XRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the X-axis range.

## YRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the Y-axis range.

### ZRANGE

Set this keyword to a 2-element array of the form [*min*, *max*] specifying the Z-axis range.

### XTITLE

Set this keyword to a string specifying the title for the X axis of the plot.

### YTITLE

Set this keyword to a string specifying the title for the Y axis of the plot.

### ZTITLE

Set this keyword to a string specifying the title for the Z axis of the plot.

## Examples

The following example displays two curves in XPLOT3D, using a custom plotting symbol for one of the curves:

```
;Define plot data:
X = INDGEN(20)
Y1 = SIN(X/3.)
Y2 = COS(X/3.)
Z = X

;Display curve 1 in XPLOT3D:
XPLOT3D, X, Y1, Z, NAME='Curve1', THICK=2

;Define custom plotting symbols:
oOrb = OBJ_NEW('orb', COLOR=[0, 0, 255])
oOrb->Scale, .75, .1, .5
oSymbol = OBJ_NEW('IDLgrSymbol', oOrb)

;Overplot curve 2 in XPLOT3D:
XPLOT3D, X, Y2, Z, COLOR=[0,255,0], NAME='Curve2', $
   SYMBOL=oSymbol, THICK=2, /OVERPLOT
```

This code results in the following:

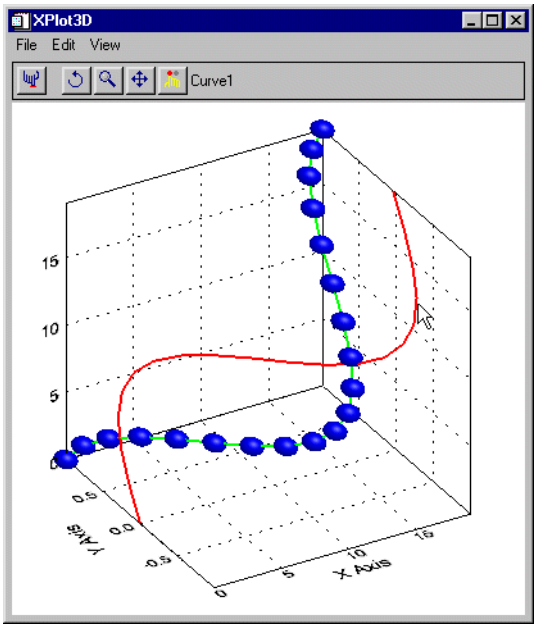

*Figure 37: Two curves displayed in XPLOT3D*

## Version History

Introduced: 5.4

## See Also

IPLOT

# XREGISTERED

The XREGISTERED function returns the number of instances of the widget named as its argument that are currently registered with the XMANAGER. The registered widget is brought to the front of the desktop unless the NOSHOW keyword is set.

If the specified widget is not currently registered with XMANAGER, XREGISTERED returns zero.

This routine is written in the IDL language. Its source code can be found in the file `xregistered.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = XREGISTERED(*Name* [, /NOSHOW] )

## Arguments

### Name

A string containing the name of the widget in question.

**Note**

XREGISTERED checks for *Name* in a COMMON block created by XMANAGER. The stored name is case-sensitive.

## Keywords

### NOSHOW

If the widget in question is registered, it is brought to the front of all the other windows by default. Set this keyword to keep the widget from being brought to the front.

## Examples

Suppose that you have a widget program that registers itself with the XMANAGER with the command:

```
XMANAGER, 'mywidget', base
```

You could limit this widget to one instantiation by adding the following line as the first line (after the procedure definition statement) of the widget creation routine:

```
IF ( XREGISTERED('mywidget') NE 0 ) THEN RETURN
```

## Version History

Introduced: Pre 4.0

XMANAGER

# XROI

The XROI procedure is a utility for interactively defining regions of interest (ROIs), and obtaining geometry and statistical data about these ROIs.

This routine is written in the IDL language. Its source code can be found in the file `xroi.pro` in the `lib/utilities` subdirectory of the IDL distribution.

**Note**

See "Using XROI" on page 2460, for detailed information describing importing images, modifying image and ROI colors, retrieving ROI information and growing regions.

## Syntax

XROI [, *ImageData*] [, *R*] [, *G*] [, *B*] [, /BLOCK]
[[, /FLOATING] , GROUP=*widget_ID*] [, /MODAL] [, REGIONS_IN=*value*]
[, REGIONS_OUT=*value*] [, REJECTED=*variable*] [, RENDERER={0 | 1}]
[, ROI_COLOR=*[r, g, b] or variable*] [, ROI_GEOMETRY=*variable*]
[, ROI_SELECT_COLOR=*[r, g, b] or variable*] [, STATISTICS=*variable*]
[, TITLE=*string*] [, TOOLS=*string/string array* {valid values are 'Translate-Scale', 'Rectangle', 'Ellipse', 'Freehand Draw', 'Polygon Draw', and 'Selection'}]
[, X_SCROLL_SIZE=*value*] [, Y_SCROLL_SIZE=*value*]

## Arguments

### ImageData

*ImageData* is both an input and output argument. It is an array representing an 8-bit or 24-bit image to be displayed. *ImageData* can be any of the following:

- [*m*, *n*] — 8-bit image
- [3, *m*, *n*] — 24-bit image
- [*m*, 3, *n*] — 24-bit image
- [*m*, *n*, 3] — 24-bit image

If *ImageData* is not supplied, the user will be prompted for a file via DIALOG_PICKFILE. On output, *ImageData* will be set to the current image data. (The current image data can be different than the input image data if the user imported an image via the **File** → **Import Image** menu item.)

### R, G, B

*R*, *G*, and *B* are arrays of bytes representing red, green, or blue color table values, respectively. *R*, *G*, and *B* are both input and output arguments. On input, these values are applied to the image if the image is 8-bit. To get the red, green, or blue color table values for the image on output from XROI, specify a named variable for the appropriate argument. (If the image is 24-bit, this argument will output a 256-element byte array containing the values given at input, or BINDGEN(256) if the argument was undefined on input.)

## Keywords

### BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XROI block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

### FLOATING

Set this keyword, along with the GROUP keyword, to create a floating top-level base widget. If the windowing system provides Z-order control, floating base widgets appear above the base specified as their group leader. If the windowing system does not provide Z-order control, the FLOATING keyword has no effect.

**Note**

Floating widgets must have a group leader. Setting this keyword without also setting the GROUP keyword causes an error.

### GROUP

Set this keyword to the widget ID of the widget that calls XROI. When this keyword is specified, the death of the caller results in the death of XROI.

## MODAL

Set this keyword to block other IDL widgets from receiving events while XROI is active.

## REGIONS_IN

Set this keyword to an array of IDLgrROI references. This allows you to open XROI with previously defined regions of interest (see Example 3). This is also useful when using a loop to open multiple images in XROI. By using the same named variable for both the REGIONS_IN and REGIONS_OUT keywords, you can reuse the same ROIs in multiple images (see Example 2). This keyword also accepts –1, or OBJ_NEW() (Null object) to indicate that there are no ROIs to read in. This allows you to assign the result of a previous REGIONS_OUT to REGIONS_IN without worrying about the case where the previous REGIONS_OUT is undefined.

## REGIONS_OUT

Set this keyword to a named variable that will contain an array of IDLgrROI references. This keyword is assigned the null object reference if there are no ROIs defined. By using the same named variable for both the REGIONS_IN and REGIONS_OUT keywords, you can reuse the same ROIs in multiple images (see Example 2).

**Note**

This keyword must be used in conjunction with the BLOCK keyword.

## REJECTED

Set this keyword to a named variable that will contain those REGIONS_IN that are not in REGIONS_OUT. The objects defined in the variable specified for REJECTED can be destroyed with a call to OBJ_DESTROY, allowing you to perform cleanup on objects that are not required (see Example 2). This keyword is assigned the null object reference if no REGIONS_IN are rejected by the user.

**Note**

This keyword must be used in conjunction with the BLOCK keyword.

## RENDERER

Set this keyword to an integer value to indicate which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation (the default)

## ROI_COLOR

This keyword is both an input and an output parameter. Set this keyword to a 3-element byte array, [*r*, *g*, *b*], indicating the color of ROI outlines when they are not selected. This color will be used by XROI unless and until the color is changed by the user via the "Unselected Outline Color" portion of the "ROI Outline Colors" dialog (which is accessed by selecting **Edit → ROI Outline Colors**). If this keyword is assigned a named variable, that variable will be set to the current [*r*, *g*, *b*] value at the time that XROI returns.

## ROI_GEOMETRY

Set this keyword to a named variable that will contain an array of anonymous structures, one for each ROI that is valid when this routine returns. The structures will contain the following fields:

| Field | Description |
|---|---|
| area | The area of the region of interest, in square pixels. |
| centroid | The coordinates (*x*, *y*, *z*) of the centroid of the region of interest, in pixels. |
| perimeter | The perimeter of the region of interest, in pixels. |

*Table 112: Fields of the structure returned by ROI_GEOMETRY*

If there are no valid regions of interest when this routine returns, ROI_GEOMETRY will be undefined.

**Note**

If there are no REGIONS_IN, XROI must either be modal or must block control flow in order for ROI_GEOMETRY to be defined upon exit from XROI. Otherwise, XROI will return before an ROI can be defined, and ROI_GEOMETRY will therefore be undefined.

**Note**

This keyword must be used in conjunction with the BLOCK keyword.

## ROI_SELECT_COLOR

This keyword is both an input and an output parameter. Set this keyword to a 3-element byte array, [*r*, *g*, *b*], indicating the color of ROI outlines when they are selected. This color will be used by XROI unless and until the color is changed by the user via the “Selected Outline Color” portion of the “ROI Outline Colors” dialog (which is accessed by selecting **Edit → ROI Outline Colors**). If this keyword is assigned a named variable, that variable will be set to the current [*r*, *g*, *b*] value at the time that XROI returns.

## STATISTICS

Set this keyword to a named variable to receive an array of anonymous structures, one for each ROI that is valid when this routine returns. The structures will contain the following fields:

| Field | Description |
|---|---|
| count | Number of pixels in region. |
| minimum | Minimum pixel value. |
| maximum | Maximum pixel value. |
| mean | Mean pixel value. |
| stddev | Standard deviation of pixel values. |

*Table 113: Fields of the structure returned by STATISTICS*

If *ImageData* is 24-bit, or if there are no valid regions of interest when the routine exits, STATISTICS will be undefined.

**Note**

If there are no REGIONS_IN, XROI must either be modal or must block control flow in order for STATISTICS to be defined upon exit from XROI. Otherwise, XROI will return before an ROI can be defined, and STATISTICS will therefore be undefined.

## TITLE

Set this keyword to a string to appear in the XROI title bar.

## TOOLS

Set this keyword a string or vector of strings from the following list to indicate which ROI manipulation tools should be supported when XROI is run:

- 'Translate-Scale' — Translation and scaling of ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.
- 'Rectangle' — Rectangular ROI drawing. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.
- 'Ellipse' — Elliptical ROI drawing. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.
- 'Freehand Draw' — Freehand ROI drawing. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.
- 'Polygon Draw' — Polygon ROI drawing. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.
- 'Selection' — ROI selection. Mouse down/up selects the nearest region. The nearest vertex in that region is identified with a crosshair symbol.

If more than one string is specified, a series of bitmap buttons will appear at the top of the XROI widget in the order specified (to the right of the fixed set of bitmap buttons used for saving regions, displaying region information, copying to clipboard, and flipping the image). If only one string is specified, no additional bitmap buttons will appear, and the manipulation mode is implied by the given string. If this keyword is not specified, bitmap buttons for all three manipulation tools are included on the XROI toolbar.

## X_SCROLL_SIZE

Set this keyword to the width of the scroll window. If this keyword is larger than the image width then it will be set to the image width. The default is to use the image width or the screen width, whichever is smaller.

### Y_SCROLL_SIZE

Set this keyword to the height of the scroll window. If this keyword is larger than the image height then it will be set to the image height. The default is to use the image height or the screen height, whichever is smaller.

## Using XROI

XROI displays a top-level base with a menu, toolbar and draw widget. After defining an ROI, the **ROI Information** window appears, as shown in the following figure:

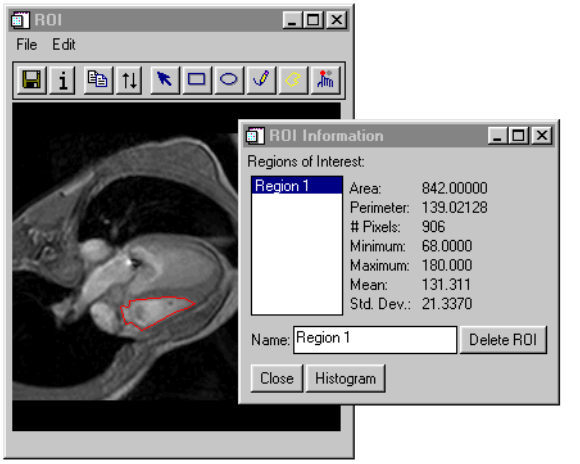

*Figure 38: The XROI Utility*

As you move the mouse over an image, the x and y pixel locations are shown in the status line on the bottom of the XROI window. For 8-bit images, the data value (z) is also shown. If an ROI is defined, the status line also indicates the mouse position relative to the ROI using the text “Inside”, “Outside”, “On Edge,” or “On Vertex.”

### The XROI Toolbar

The XROI toolbar contains the following buttons:

**Save:** Opens a file selection dialog for saving the currently defined ROIs to a save file.

**Info:** Opens the **ROI Information** window.

**Copy:** Copies the contents of the display area to the clipboard.

**Flip:** Flips image vertically. Note that only the image is flipped; any ROIs that have been defined do not move.

Depending on the value of the TOOLS keyword, the XROI toolbar may also contain the following buttons:

**Translate/ Scale:** Click this button to translate or scale ROIs. Mouse down inside the bounding box selects a region, mouse motion translates (repositions) the region. Mouse down on a scale handle of the bounding box enables scaling (stretching, enlarging and shrinking) of the region according to mouse motion. Mouse up finishes the translation or scaling.

**Draw Rectangle:** Click this button to draw rectangular ROIs. Mouse down positions one corner of the rectangle, mouse motions creates the rectangle, positioning the rectangle's opposite corner, mouse up finishes the rectangular region.

**Draw Ellipse:** Click this button to draw elliptical ROIs. Mouse down positions the center of the ellipse, mouse motion positions the corner of the ellipse's imaginary bounding box, mouse up finishes the elliptical region.

**Draw Freehand:** Click this button to draw freehand ROIs. Mouse down begins a region, mouse motion adds vertices to the region (following the path of the mouse), mouse up finishes the region.

**Draw Polygon:** Click this button to draw polygon ROIs. Mouse down begins a region, subsequent mouse clicks add vertices, double-click finishes the region.

**Select:** Click this button to select an ROI region. Clicking the image causes a cross hairs symbol to be drawn at the nearest vertex of the selected ROI.

## Importing an Image into XROI

To import an image into XROI, select **File → Import Image**. This opens a DIALOG_READ_IMAGE dialog, which can be used to preview and select an image.

## Changing the Image Color Table

To change the color table properties for the current image, select **Edit → Image Color Table**. This opens the CW_PALETTE_EDITOR dialog, which is a compound widget used to edit color palettes. See CW_PALETTE_EDITOR for more information. This menu item is grayed out if the image does not have a color palette.

## Changing the ROI Outline Colors

To change the outline colors for selected and unselected ROIs, select **Edit → ROI Outline Colors**. This opens the **ROI Outline Colors** dialog, which consists of two CW_RGBSLIDER widgets for interactively adjusting the ROI outline colors. The left widget is used to define the color for the selected ROI, and the right widget is used to define the color of unselected ROIs. You can select the RGB, CMY, HSV, or HLS color system from the **Color System** drop-down list.

## Viewing ROI Information

To view geometry and statistical data about the currently selected ROI, click the **Info** button or select **Edit → ROI Information**. This opens the **ROI Information** dialog, which displays area, perimeter, number of pixels, minimum and maximum pixel values, mean, and standard deviation. Values for statistical information (minimum, maximum, mean, and standard deviation) appear as “N/A” for 24-bit images.

## Viewing a Histogram Plot for an ROI

To view a histogram for an ROI, use either the shortcut menu or the ROI Information dialog.

To view an ROI’s histogram plot using the shortcut menu:

1. Position the cursor on the line defining the boundary of an ROI in the drawing window and click the right mouse button. This selects the region and brings up its shortcut menu.
2. Select the **Plot Histogram** menu option from the shortcut menu.

To view an ROI’s histogram plot using the ROI Information dialog:

1. Open the ROI Information dialog by clicking the **Info** button or selecting **Edit → ROI Information**.

2. Select a region from the list and click the **Histogram** button on the ROI Information dialog.

Either of the previous methods opens a LIVE_PLOT dialog showing the ROI's histogram that can be used to interactively control the plot properties.

**Note**

XROI's histogram plot feature now supports RGB images.

## Growing an ROI

Once a region has been created, it may be used as a source ROI for region growing. Region growing is a process of generating one or more new ROIs based upon the image pixel values that fall within the source ROI and the values of the neighboring pixels. New pixels are added to the new grown region if those image pixel values fall within a specified threshold.

**Note**

This option is an interactive implementation of the REGION_GROW function.

To create a new, grown region, do the following:

1. Within the draw area, click the right mouse button on the ROI that is to be grown. This will select the region and bring up its shortcut menu.
2. Select **Grow Region → By threshold** or select **Grow Region → By std. dev. multiple** from the shortcut menu to control how the region is grown.

   The **By threshold** option grows the region to include all neighboring pixels that fall within a specified threshold range. By default, the range is defined by the minimum and maximum pixel values occurring within the original region. To specify a different threshold range, see Using the Region Grow Properties Dialog in the following section.

   The **By std. dev. multiple** option grows a region to include all neighboring pixels that fall within the range of:

   ```
   Mean +/- StdDevMultiplier * StdDev
   ```

   where `Mean` is the mean value of the pixel values within the source ROI, `StdDevMultiplier` is a multiplier that is set using the Region Grow Properties dialog (described below), and `StdDev` is the sample standard deviation of the pixel values within the original region.

## Using the Region Grow Properties Dialog

The Region Grow Properties dialog allows you to view and edit the properties associated with a region growing process. To bring up the Region Grow Properties dialog, do one of the following:

- Click the right mouse button on an ROI in the drawing window and select **Grow Region → Properties...** shortcut menu option.
- Select **Edit → Region Grow Properties**... from the XROI menu bar.

This brings up the Region Grow Properties dialog, shown in the following figure.

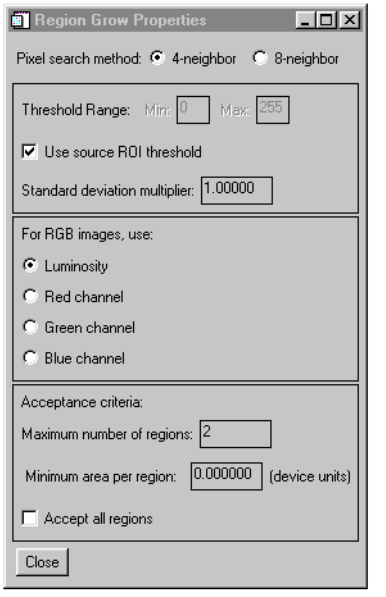

*Figure 39: XROI's Region Grow Properties Dialog*

The Region Grow Properties dialog offers the following options:

| Option | Description |
|---|---|
| Pixel search method: | Describes which pixels are searched when growing the original ROI. The option are:<br>• **4-neighbor** — Searches only the four neighboring pixels that share a common edge with the current pixel. This is the default.<br>• **8-neighbor** — Searches all eight neighboring pixels, including those that are located diagonally relative to the original pixel and share a common corner. |
| Threshold range: | Represents the minimum and maximum image pixel values that are to be included in the grown region when using the **Grow Region → By threshold** option (described in "Growing an ROI" on page 2463). By default, the range of pixel values used are those occurring in the ROI to be grown.<br>To change the threshold values, uncheck **Use source ROI threshold** and enter the minimum and maximum threshold values in the **Min:** and **Max:** fields provided. |
| Standard deviation multiplier: | Represents the factor by which the sample standard deviation of the original ROI's pixel values is multiplied. This factor only applies when the **Grow Region → By std. dev. multiple** option (described in "Growing an ROI" on page 2463) is used.<br>Change the multiplier value by typing the value into the **Standard deviation multiplier** field provided. |

*Table 114: Options of the Region Grow Properties Dialog*

| Option | Description |
|---|---|
| For RGB image, use: | Determines the basis of region growing for an RGB (rather than indexed) image. The image data values used when growing a RGB region can be one of the following:<br>• **Luminosity** — Uses the luminosity values associated with an RGB image. This is the default method. Luminosity is computed as:<br>Luminosity = (0.3 * Red) + (0.59 * Green) + (0.11 * Blue)<br>• **Red Channel**, **Green Channel** or **Blue Channel** — Uses the ROI's red, green or blue channel as a basis for region growing. Click the channel's associated button to specify the channel to be used.<br>**Note -** For indexed images, the image data itself is always used for region growing. |
| Acceptance criteria: | Determines which contours of the grown region are accepted as new regions, (which will also be displayed in the draw area and in the ROI Information dialog list of regions). The region growing process can result in a large number of contours, some of which may be considered insignificant. By default, no more than two regions (those with the greatest geometrical area) are accepted. Modify the acceptance criteria by altering the following values:<br>• **Maximum number of regions:** — Specifies the upper limit of the number of regions to create when growing an ROI.<br>• **Minimum area per region:** — Specifies that only contours having a geometric area (computed in device coordinates) of at least the value stated are accepted and displayed.<br>• **Accept all regions:** — Select this option to accept all generated contours, regardless of count or area. |

*Table 114: Options of the Region Grow Properties Dialog (Continued)*

### Deleting an ROI

An ROI can be deleted using either the shortcut menu or using the ROI Information dialog.

To delete an ROI using the shortcut menu:

1. Click the right mouse button on the line defining the boundary of the ROI in the drawing area that you wish to delete. This selects the region and bring up the shortcut menu.
2. Select the **Delete** menu option from the shortcut menu.

To delete an ROI using the ROI Information dialog:

1. Click the **Info** button or select **Edit → ROI Information**. This opens the **ROI Information** dialog.
2. In the **ROI Information** dialog, select the ROI you wish to delete from the list of ROIs. You can also select an ROI by clicking the **Select** button on the XROI toolbar, then clicking on an ROI on the image.
3. Click the **Delete ROI** button.

## Examples

### Example 1

This example opens a single image in XROI:

```
image = READ_PNG(FILEPATH('mineral.png', $
   SUBDIR=['examples', 'data']))
XROI, image
```

### Example 2

This example reads 3 images from the file `mr_abdomen.dcm`, and calls XROI for each image. A single list of regions is maintained, saving the user from having to redefine regions on each image:

```
;Read 3 images from mr_abdomen.dcm and open each one in XROI:
FOR i=0,2 DO BEGIN
   image = READ_DICOM(FILEPATH('mr_abdomen.dcm',$
      SUBDIR=['examples', 'data']), IMAGE_INDEX=i)
   XROI, image, r, g, b, REGIONS_IN = regions, $
      REGIONS_OUT = regions, $
      ROI_SELECT_COLOR = roi_select_color, $
      ROI_COLOR = roi_color, REJECTED = rejected, /BLOCK
```

```
   OBJ_DESTROY, rejected
ENDFOR

OBJ_DESTROY, regions
```

Perform the following steps:

1. Draw an ROI on the first image, then close that XROI window. Note that the next image contains the ROI defined in the first image. This is accomplished by setting REGIONS_IN and REGIONS_OUT to the same named variable in the FOR loop of the above code.
2. Draw another ROI on the second image.
3. Click the **Select** button and select the first ROI. Then click the **Info** button to open the **ROI Information** window, and click the **Delete ROI** button.
4. Close the second XROI window. Note that the third image contains the ROI defined in the second image, but not the ROI deleted on the second image. This example sets the REJECTED keyword to a named variable, and calls OBJ_DESTROY on that variable. Use of the REJECTED keyword is not necessary to prevent deleted ROIs from appearing on subsequent images, but allows you perform cleanup on objects that are no longer required.

## Example 3

XROI's **File** → **Save ROIs** option allows you to save selected regions of interest. This example shows how to restore such a save file. Suppose you have a file named `mineralRoi.sav` that contains regions of interest selected in the `mineral.png` image file. You would need to complete the following steps to restore the file:

1. First, restore the file, `mineralRoi.sav`. Provide a value for the RESTORE procedure's RESTORED_OBJECTS keyword. Using the scenario stated above, you could enter the following:

```
RESTORE, 'mineralRoi.sav', RESTORED_OBJECTS = myRoi
```

2. Pass the restored object data containing your regions of interest into XROI by specifying `myRoi` as the value for REGIONS_IN as follows:

```
XROI, READ_PNG(FILEPATH('mineral.png', SUBDIRECTORY = $
    ['examples', 'data'])), REGIONS_IN = myRoi
```

   This opens the previously selected regions of interest in the XROI utility.

## Version History

IIMAGE

# XSQ_TEST

The XSQ_TEST function computes the Chi-square goodness-of-fit test between observed frequencies and the expected frequencies of a theoretical distribution.

Expected frequencies of magnitude less than 5 are combined with adjacent elements resulting in a reduction of cells used to formulate the chi-squared test statistic. If the observed frequencies differ significantly from the expected frequencies, the Chi-square test statistic will be large and the fit is poor. This situation requires the rejection of the hypothesis that the given observed frequencies are an accurate approximation to the expected frequency distribution.

This routine is written in the IDL language. Its source code can be found in the file `xsq_test.pro` in the `lib` subdirectory of the IDL distribution.

## Syntax

*Result* = XSQ_TEST( *Obfreq*, *Exfreq* [, EXCELL=*variable*] [, OBCELL=*variable*] [, RESIDUAL=*variable*] )

## Return Value

The result is a two-element vector containing the Chi-square test statistic X2 and the one-tailed probability of obtaining a value of X2 or greater.

## Arguments

### Obfreq

An *n*-element integer, single-, or double-precision floating-point vector containing observed frequencies.

### Exfreq

An *n*-element integer, single-, or double-precision floating-point vector containing expected frequencies.

# Keywords

## EXCELL

Set this keyword to a named variable that will contain a vector of expected frequencies used to formulate the Chi-square test statistic. If each of the expected frequencies contained in *Exfreq*, has a magnitude of 5 or greater, then this vector is identical to *Exfreq*. If *Exfreq* contains elements of magnitude less than 5, adjacent expected frequencies are combined. The identical combinations are performed on the corresponding elements of *Obfreq*.

## OBCELL

Set this keyword to a named variable that will contain a vector of observed frequencies used to formulate the Chi-square test statistic. The elements of this vector are often referred to as the “cells” of the observed frequencies. The length of this vector is determined by the length of EXCELL described below.

## RESIDUAL

Set this keyword to a named variable that will contain a vector of signed differences between corresponding cells of observed frequencies and expected frequencies.

```
RESIDUAL[i] = OBCELL[i] - EXCELL[i].
```

The length of this vector is determined by the length of EXCELL described above.

# Examples

```
; Define the vectors of observed and expected frequencies:
obfreq = [2, 1, 4, 15, 10, 5, 3]
exfreq = [0.5, 2.1, 5.9, 10.3, 10.7, 7.0, 3.5]

; Test the hypothesis that the given observed frequencies are an
; accurate approximation to the expected frequency distribution:
result = XSQ_TEST(obfreq, exfreq)
PRINT, result
```

### IDL Output

```
3.05040       0.383920
```

Since the vector of expected frequencies contains elements of magnitude less than 5, adjacent expected frequencies are combined resulting in fewer cells. The identical combinations are performed on the corresponding elements of observed frequencies.

The computed value of 0.383920 indicates that there is no reason to reject the proposed hypothesis at the 0.05 significance level.

## Version History

Introduced: 4.0

CTI_TEST

# XSURFACE

The XSURFACE procedure is a utility that provides a graphical interface to the SURFACE and SHADE_SURF commands. Different controls are provided to change the viewing angle and other plot parameters. The command used to generate the resulting surface plot is shown in a text window. Note that this procedure does not accept SURFACE or SHADE_SURF keywords.

This routine is written in the IDL language. Its source code can be found in the file `xsurface.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XSURFACE, *Data* [, /BLOCK] [, GROUP=*widget_id*]

## Arguments

### Data

The two-dimensional array to display as a wire-mesh or shaded surface.

## Keywords

### BLOCK

Set this keyword to have XMANAGER *block* when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting BLOCK=1 will cause *all* widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XSURFACE block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

### GROUP

Set this keyword to the widget ID of the widget that calls XSURFACE. When GROUP is specified, the death of the calling widget results in the death of XSURFACE.

## Examples

```
; Make a 2-D array:
z = DIST(30)

; Call XSURFACE. The XSURFACE widget appears:
XSURFACE, z
```

## Version History

Introduced: Pre 4.0

# XVAREDIT

The XVAREDIT procedure is a utility that provides a widget-based editor for any IDL variable. Use the input fields to change desired values of the variable or array. Click “Accept” to write the new values into the variable. Click “Cancel” to exit XVAREDIT without saving changes.

This routine is written in the IDL language. Its source code can be found in the file `xvaredit.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XVAREDIT, *Var* [, NAME='*variable_name*'{ignored if variable is a structure}] [, GROUP=*widget_id*] [, X_SCROLL_SIZE=*columns*] [, Y_SCROLL_SIZE=*rows*]

## Arguments

### Var

The variable to be edited. On output, this variable contains the edited value if the user selects the “Accept” button, or the original value if the user selects the “Cancel” button.

## Keywords

### NAME

The NAME of the variable. This keyword is overwritten with the structure name if the variable is a structure.

### GROUP

The widget ID of the widget that calls XVAREDIT. When this ID is specified, a death of the caller results in a death of XVAREDIT.

### X_SCROLL_SIZE

Set this keyword to the column width of the scrolling viewport. The default is 4.

### Y_SCROLL_SIZE

Set this keyword to the row width of the scrolling viewport. The default is 4.

## Version History

Introduced: Pre 4.0

# XVOLUME

The XVOLUME procedure is a utility for viewing and interactively manipulating volumes and isosurfaces.

This routine is written in the IDL language. Its source code can be found in the file `xvolume.pro` in the `lib/utilities` subdirectory of the IDL distribution.

**Tip**

The XVOLUME_ROTATE and XVOLUME_WRITE_IMAGE procedures, which can be called only after a call to XVOLUME, can be used to easily create animations of volumes and isosurfaces displayed in XVOLUME. See XVOLUME_ROTATE for an example.

## Using XVOLUME

XVOLUME displays a resizeable top-level base with a toolbar, a menu, a graphical interface for controlling volume and isosurface properties, and a draw widget for displaying and manipulating the volume, as shown in the following figure:

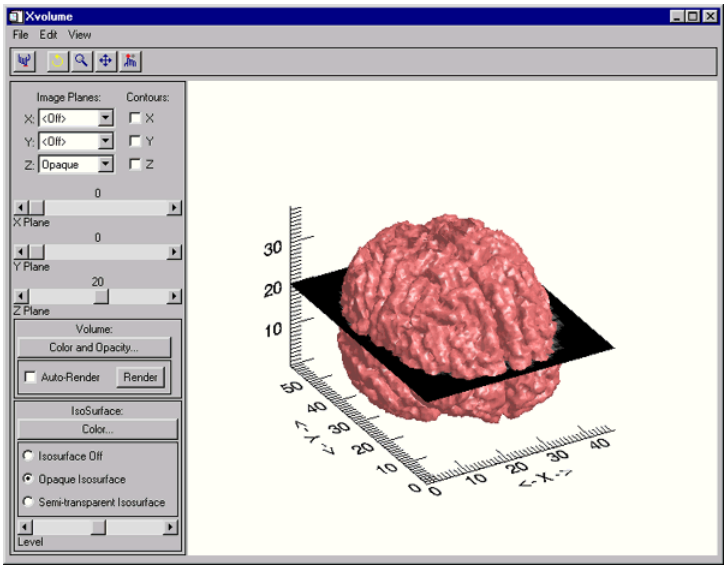

*Figure 40: The XVOLUME Utility*

## The XVOLUME Toolbar

The XVOLUME toolbar contains the following buttons.

**Note**

If you have the **Auto-Render** option selected, the Rotate, Zoom, and Pan features may be more difficult to use. For the best performance while manipulating the orientation of a volume using these features, uncheck the **Auto-Render** option.

**Reset:** Resets rotation, scaling, and panning.

**Rotate:** Click the left mouse button on the volume and drag to rotate.

**Zoom:** Click the left mouse button on the volume and drag to zoom in or out.

**Pan:** Click the left mouse button on the volume and drag to pan.

**Select:** Click in the draw widget to identify the selected item. A name identifying the selected item is displayed next to the Select button.

## The XVOLUME Interface

The XVOLUME interface provides the following elements for controlling the display of image planes and contours, volumes, and isosurfaces:

### Image Planes and Contours

Image planes and contours allow you to visualize the values associated with the volume or isosurface at a specified X, Y, or Z plane.

- **Image Planes** — Select one of the following options from the drop-down list for each dimension to control the display of image planes:
  - **Off**: Turns off the image plane display.
  - **Opaque**: Displays an opaque image plane at the location specified by the corresponding plane slider.
  - **Transparent**: Displays a transparent image plane at the location specified by the corresponding plane slider. The transparency value of the plane is taken from the volume at the current location of the image plane.

- **Contours** — Check this option to display contours on the specified plane at the location specified by corresponding the plane slider.
- **Plane Sliders** — Move these sliders to change the position of the plane in each dimension.

### Volume

- **Color and Opacity**: Click this button to change the color and/or opacity of the current volume. This opens a CW_PALETTE_EDITOR dialog, which is a compound widget used to edit color palettes. See CW_PALETTE_EDITOR for more information.
- **Auto-Render**: Select this option to have rendering executed automatically after each change you make to the volume. If **Auto-Render** is unchecked, you must manually click the **Render** button to see changes you have made to the volume. If **Auto-Render** is checked, the **Render** button will be grayed out.
- **Render**: Click on this button to execute rendering computations and display the current volume. If **Auto-Render** is checked, this button will be grayed out.

### Isosurface

An isosurface is a 3-D surface on which the data values are constant along the entire surface. Use the following elements to control the appearance of the isosurface:

- **Color**: Click this button to change the color system and/or values for the current isosurface. This opens a CW_RGBSLIDER dialog, which is a compound widget that provides a drop-down list for selecting the RGB, CMY, HSV, or HLS color system, and three sliders for adjusting the values associated with each color system.
- **Isosurface Off**: Select this option to turn off the isosurface display.
- **Opaque Isosurface**: Select this option to display an opaque isosurface.
- **Semi-transparent Isosurface**: Select this option to display a semi-transparent isosurface.
- **Level**: Use this slider to adjust the threshold value of the isosurface.

## Syntax

XVOLUME, *Vol*, [, /BLOCK] [, GROUP=*widget_id*] [, /INTERPOLATE] [, /MODAL] [, RENDERER={0 | 1}] [, /REPLACE] [, SCALE=*value*] [, /TEST] [, XSIZE=*pixels*] [, YSIZE=*pixels*]

# Arguments

## Vol

A 3-dimensional array of the form [*x*, *y*, *z*] that specifies a data volume.

# Keywords

## BLOCK

Set this keyword to have XMANAGER block when this application is registered. By default, BLOCK is set equal to zero, providing access to the command line if active command line processing is available. Note that setting the BLOCK keyword causes all widget applications to block, not just this application. For more information, see the documentation for the NO_BLOCK keyword to XMANAGER.

**Note**

Only the outermost call to XMANAGER can block. Therefore, to have XVOLUME block, any earlier calls to XMANAGER must have been called with the NO_BLOCK keyword. See the documentation for the NO_BLOCK keyword to XMANAGER for an example.

## GROUP

Set this keyword to the widget ID of the widget that calls XVOLUME. When this keyword is specified, the death of the caller results in the death of XVOLUME.

## INTERPOLATE

Set this keyword to indicate that trilinear interpolation is to be used when rendering the volume and the image planes. Setting this keyword improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default.

## MODAL

Set this keyword to block processing of events from other widgets until the user quits XVOLUME. The MODAL keyword does not require a group leader to be specified. If no group leader is specified, and the MODAL keyword is set, XVOLUME fabricates an invisible group leader for you.

**Note**

To be modal, XVOLUME does not require that its caller specify a group leader. This is unlike other IDL widget procedures such as XLOADCT, which, to be modal, do require that their caller specify a group leader. These other procedures were implemented this way to encourage the caller to create a modal widget that will be well-behaved with respect to layering and iconizing. (See "Iconizing, Layering, and Destroying Groups of Top-Level Bases" on page 2128 for more information.)

To provide a simple means of invoking XVOLUME as a modal widget in applications that contain no other widgets, XVOLUME can be invoked as MODAL without specifying a group leader, in which case XVOLUME fabricates an invisible group leader for you. For applications that contain multiple widgets, however, it is good programming practice to supply an appropriate group leader when invoking XVOLUME, /MODAL. As with other IDL widget procedures with names prefixed with "X", specify the group leader via the GROUP keyword.

## RENDERER

Set this keyword to an integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL (the default)
- 1 = IDL's software implementation

## REPLACE

If this keyword is set, and there is a current instance of XVOLUME running, the volume displayed in XVOLUME is replaced with the volume specified by *Vol*. For example, display volume1 using the command

```
XVOLUME, volume1
```

To replace volume1 with volume2, you would use the command

```
XVOLUME, volume2, /REPLACE
```

## SCALE

Set this keyword to the zoom factor for the initial view. The default is 1/SQRT(3). This default value provides the largest possible view of the volume, while ensuring that no portion of the volume will be clipped by the XVOLUME window, regardless of the volume's orientation.

When using the SCALE keyword for XVOLUME, you can scale with a 3-element array of values [x, y, z].

### TEST

If set, the *Vol* argument is not required (and is ignored if provided). A volume of random numbers is displayed instead. This allows you to test code that uses XVOLUME without having to specify volume data.

### XSIZE

The width of the drawable area in pixels.

### YSIZE

The height of the drawable area in pixels.

## Examples

Create a volume and display using XVOLUME:

```
; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol
```

## Version History

Introduced: 5.4

## See Also

IVOLUME, XVOLUME_ROTATE, XVOLUME_WRITE_IMAGE, IDLgrVolume, INTERPOLATE, ISOSURFACE, SHADE_VOLUME, SLICER3, “Volume Objects” in Chapter 32 of the *Using IDL* manual.

# XVOLUME_ROTATE

The XVOLUME_ROTATE procedure is used to programmatically rotate the volume currently displayed in XVOLUME. XVOLUME must be called prior to calling XVOLUME_ROTATE. This procedure can be used to create animations of volumes and isosurfaces.

This routine is written in the IDL language. Its source code can be found in the file `xvolume_rotate.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XVOLUME_ROTATE, *Axis*, *Angle* [, /PREMULTIPLY]

## Arguments

### Axis

A 3-element vector of the form [*x*, *y*, *z*] describing the axis about which the model is to be rotated.

### Angle

The amount of rotation, measured in degrees.

## Keywords

### PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

## Examples

The following example creates an animation of the volume currently displayed in XVOLUME. It does this by rotating the volume through 360 degrees in increments of 10 degrees using XVOLUME_ROTATE, and writing the volume to a BMP file for each increment using XVOLUME_WRITE_IMAGE. It then loops through the images and uses TV to display each image.

First, display a volume as follows:

```
; Create a volume:
vol = BYTSCL(RANDOMU((SEED=0),5,5,5))
vol = CONGRID(vol, 30,30,30)

; Display volume:
XVOLUME, vol
```

Now, use the XVOLUME interface to modify the orientation and appearance of the volume or isosurface as desired. Once you have the volume or isosurface displayed the way you want it, run the following program:

```
PRO spin_volume

   inc = 10. ; degrees.
   ; Create images
   FOR i=0,(360./inc)-2 DO BEGIN
      XVOLUME_WRITE_IMAGE, $
         'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', 'bmp'
      XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY
   ENDFOR
   XVOLUME_ROTATE, [0,0,1], inc, /PREMULTIPLY

   ; Read images
   img = READ_BMP('spin0.bmp')
   siz = SIZE(img, /DIM)
   arr = BYTARR(3, siz[1], siz[2], 360./inc-1)
   FOR i=0,360./inc-2 DO BEGIN
      img = READ_BMP( $
         'spin' + STRCOMPRESS(i, /REMOVE_ALL) + '.bmp', /RGB)
      arr[0,0,0, i] = img
      PRINT, i
   ENDFOR

   ; Display animation
   FOR i=0,2 DO BEGIN ; num rotations
      FOR j=0,(360./inc)-2 DO BEGIN
         TV, arr[*,*,*,j], /TRUE
      ENDFOR
   ENDFOR

   TV, arr[*,*,*,0], /TRUE

END
```

# Version History

Introduced: 5.4

XVOLUME, XVOLUME_WRITE_IMAGE

# XVOLUME_WRITE_IMAGE

The XVOLUME_WRITE_IMAGE procedure is used to write the volume currently displayed in XVOLUME to an image file with the specified name and file format. XVOLUME must be called prior to calling XVOLUME_WRITE_IMAGE.

This routine is written in the IDL language. Its source code can be found in the file `xvolume_write_image.pro` in the `lib/utilities` subdirectory of the IDL distribution.

## Syntax

XVOLUME_WRITE_IMAGE, *Filename*, *Format* [, DIMENSIONS=*[x, y]* ]

## Arguments

### Filename

A scalar string containing the name of the file to write.

### Format

A scalar string containing the name of the file format to write. See QUERY_IMAGE for a list of supported formats.

## Keywords

### DIMENSIONS

Set this keyword to a 2-element vector of the form [*x*, *y*] specifying the size of the output image, in pixels. If this keyword is not specified, the image will be written using the dimensions of the current XVOLUME draw widget.

## Examples

See XVOLUME_ROTATE.

## Version History

Introduced: 5.4

## See Also

XVOLUME, XVOLUME_ROTATE

# XYOUTS

The XYOUTS procedure draws text on the currently-selected graphics device starting at the designated coordinate.

Arguments *X*, *Y*, and *String* can be any combination of scalars or arrays. If the arguments are arrays, multiple strings are output.

If the optional *X* and *Y* arguments are omitted, the text is positioned at the end of the most recently output text string.

Important keywords that control the appearance and positioning of the text include: ALIGNMENT, the justification of the text; CHARSIZE, the size of the text; FONT, chooses between vector drawn and hardware fonts; COLOR, the color of the text; and ORIENTATION, the angle between the baseline of the text and the horizontal. With hardware fonts, most of the text attributes, (e.g., size and orientation), are predetermined and not changeable.

**Note**

Specify the Z coordinate with the Z keyword when positioning text in three dimensions.

## Syntax

XYOUTS, [*X*, *Y*,] *String* [, ALIGNMENT=*value*{0.0 to 1.0}] [, CHARSIZE=*value*] [, CHARTHICK=*value*] [, TEXT_AXES={0 | 1 | 2 | 3 | 4 | 5}] [, WIDTH=*variable*]

**Graphics Keywords:**[, CLIP=*[$X_0$, $Y_0$, $X_1$, $Y_1$]*] [, COLOR=*value*][, /DATA | , /DEVICE | , /NORMAL] [, FONT=*integer*]
[, ORIENTATION=*ccw_degrees_from_horiz*] [, /NOCLIP] [, /T3D] [, Z=*value*]

## Arguments

### X, Y

The horizontal and vertical coordinates used to position the string(s). *X* and *Y* are normally interpreted in data coordinates. The DEVICE and NORMAL keywords can be used to specify the coordinate units.

*X* and *Y* can be arrays of positions if *String* is an array.

### String

The string(s) to be output. This argument can be a scalar string or an array of strings. If this argument is not a string, it is converted prior to use using the default formatting rules. If *String* is an array, *X*, *Y*, and the COLOR keyword can also be arrays so that each string can have a separate location and color.

## Keywords

### ALIGNMENT

Specifies the alignment of the text baseline. An alignment of 0.0 (the default) aligns the left edge of the text baseline with the given (*x*, *y*) coordinate. An alignment of 1.0 right-justifies the text, while 0.5 results in text centered over the point (*x*, *y*).

### CHARSIZE

The overall character size for the annotation. A CHARSIZE of 1.0 is normal. Setting CHARSIZE = -1 suppresses output of the text string. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see "Scaled Hardware Fonts" on page 2490.

### CHARTHICK

The line thickness of the vector drawn font characters. This keyword has no effect when used with the hardware drawn fonts; for exceptions, see "Scaled Hardware Fonts" on page 2490. The default value is 1.0.

### TEXT_AXES

This keyword specifies the plane of vector drawn text when three-dimensional plotting is enabled. By default, text is drawn in the plane of the XY axes. The horizontal text direction is in the X plane, and the vertical text direction is in the Y plane. Values for this keyword can range from 0 to 5, with the following effects: 0 for XY, 1 for XZ, 2 for YZ, 3 for YX, 4 for ZX, and 5 for ZY. The notation ZY means that the horizontal direction of the text lies in the Z plane, and the vertical direction of the text is drawn in the Y plane.

### WIDTH

Set this keyword to a named variable in which to return the width of the text string, in normalized coordinate units.

### Graphics Keywords Accepted

See Appendix B, “Graphics Keywords” for the description of graphics and plotting keywords not listed above. CLIP, COLOR, DATA, DEVICE, FONT, NOCLIP, NORMAL, ORIENTATION, T3D, Z.

## Examples

Print the string “This is text” at device coordinate position (100,100):

```
XYOUTS, 100, 100, 'This is text', /DEVICE
```

Print an array of strings with each element of the array printed at a different location. Use larger text than in the previous example:

```
XYOUTS, [0, 200, 250], [200, 50, 100], $
   ['This', 'is', 'text'], CHARSIZE = 3, /DEVICE
```

Determine the text size for a window device before opening an on-screen window:

```
WINDOW, /FREE, /PIXMAP, XSIZE=myWinXSize, YSIZE=myWinYSize
XYOUTS, 'Check this out', WIDTH=w
WDELETE
```

*myWinXSize* and *myWinYSize* are chosen to match your onscreen window. Since we can not know the characteristics of a given device (such as character size) until a window has been opened, the PIXMAP keyword to WINDOW allows you to compute appropriate dimensions for text with an invisible window before displaying a window on your screen.

## Scaled Hardware Fonts

One example of hardware fonts which can be scaled are PostScript fonts. If you are using PostScript fonts, the keywords CHARTHICK and CHARSIZE will have an effect on a call to XYOUTS. Of the devices we provide that support hardware fonts, only the PostScript device uses scalable PostScript fonts for its “hardware” font system. All other devices use a bitmapped font technology.

Scaling is related to whether or not a device supports Hershey formatting commands when hardware fonts are used. Formatting requires the ability to scale the text on a per-character basis (i.e. for subscripting). To see if a given device supports Hershey formatting when hardware fonts are used, look at bit 12 of !D.FLAGS. You can also use this indicator to determine whether or not the hardware fonts will be scaled.

## Version History

ANNOTATE, PRINT/PRINTF

# ZOOM

The ZOOM procedure displays part of an image from the current window enlarged in a new (“zoom”) window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

**Note**

ZOOM only works with color systems.

This routine is written in the IDL language. Its source code can be found in the file `zoom.pro` in the `lib` subdirectory of the IDL distribution.

### Using ZOOM

After calling ZOOM, place the mouse cursor over an image in an IDL graphics window. Click the left mouse button to display a magnified version of the image in a new window. The zoomed image is centered around the pixel selected in the original window. Click the middle mouse button to display a menu of zoom factors. Click the right mouse button to exit the procedure.

### Using ZOOM with Draw Widgets

Note that the ZOOM procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the CW_ZOOM function.

## Syntax

ZOOM [, /CONTINUOUS] [, FACT=*integer*] [, /INTERP] [, /KEEP]
[, /NEW_WINDOW] [, XSIZE=*value*] [, YSIZE=*value*]
[, ZOOM_WINDOW=*variable*]

## Arguments

None.

## Keywords

### CONTINUOUS

Set this keyword to make the zoom window track the mouse without requiring the user to press the left mouse button. This feature only works well on fast computers.

### FACT

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

### INTERP

Set this keyword to use bilinear interpolation. The default is to use pixel replication.

### KEEP

Set this keyword to keep the zoom window after exiting the procedure.

### NEW_WINDOW

Normally, if ZOOM is called with KEEP and then called again, it will use the same window to display the new zoomed image. Set the NEW_WINDOW keyword to force ZOOM to create a new window for this purpose.

### XSIZE

Use this keyword to specify the X size of the zoom window. The default is 512.

### YSIZE

Use this keyword to specify the Y size of the zoom window. The default is 512.

### ZOOM_WINDOW

Set this keyword to a named variable that will contain the index of the zoom window. KEEP must also be set. If KEEP is not set, ZOOM_WINDOW will contain the integer -1.

## Version History

Introduced: Original

## See Also

CW_ZOOM, ZOOM_24

# ZOOM_24

The ZOOM_24 procedure displays part of a 24-bit color image from the current window expanded in a new (“zoom”) window, and provides information about cursor location and color values in an auxiliary (“data”) window. The cursor is used to mark the center of the zoom area, and different zoom factors can be specified interactively.

**Note**

ZOOM only works on 24-bit color systems.

This routine is written in the IDL language. Its source code can be found in the file `zoom_24.pro` in the `lib` subdirectory of the IDL distribution.

## Using ZOOM_24

After calling ZOOM_24, windows titled “Zoomed Image” (the zoom window) and “Pixel Values” (the data window) appear on the screen. Place the mouse cursor over a 24-bit color image in an IDL graphics window and click the left mouse button to display a magnified version of the image in the zoom window. The zoomed image is centered around the pixel selected in the original window. Move the mouse cursor in the zoom window to determine the coordinates (in the original image) and color values of individual pixels.

With the cursor located in the zoom window, click the right mouse button to return to selection mode, which allows you to either choose a new zoom center, change the zoom factor, or exit the procedure. Move the cursor to the original image and click the middle mouse button to display a menu of zoom factors, or click the right mouse button to exit the procedure.

## Using ZOOM_24 with Draw Widgets

Note that the ZOOM_24 procedure is only for use with IDL graphics windows. It should not be used with draw widgets. To obtain a zooming effect in a draw widget, use the CW_ZOOM function.

# Syntax

ZOOM_24 [, FACT=*integer*] [, /RIGHT] [, XSIZE=*value*] [, YSIZE=*value*]

# Arguments

None.

# Keywords

## FACT

Use this keyword to specify the zoom factor, which must be an integer. The default zoom factor is 4.

## RIGHT

Set this keyword to position the zoom and data windows to the right of the original window.

## XSIZE

Use this keyword to specify the X size of the zoom window. The default is 512.

## YSIZE

Use this keyword to specify the Y size of the zoom window. The default is 512.

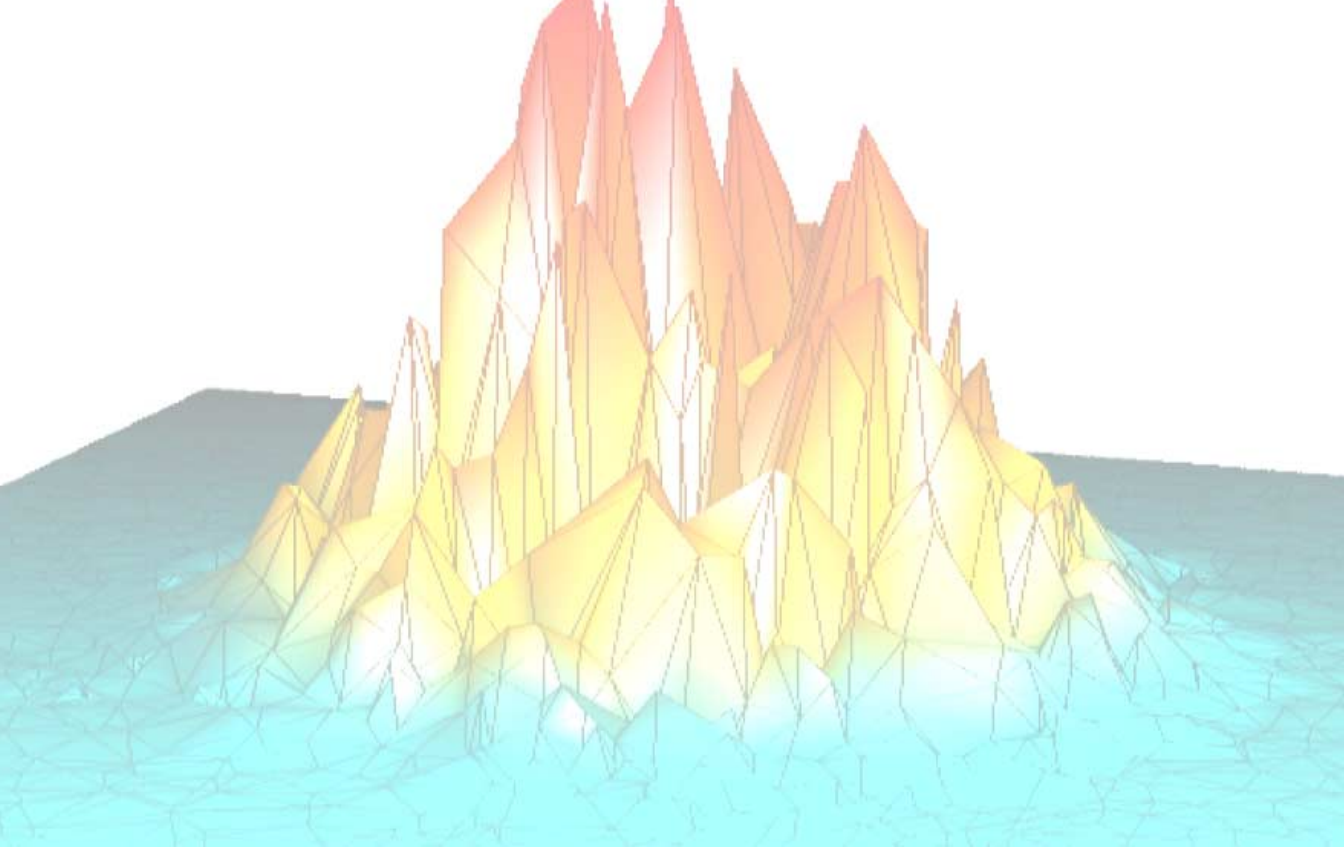
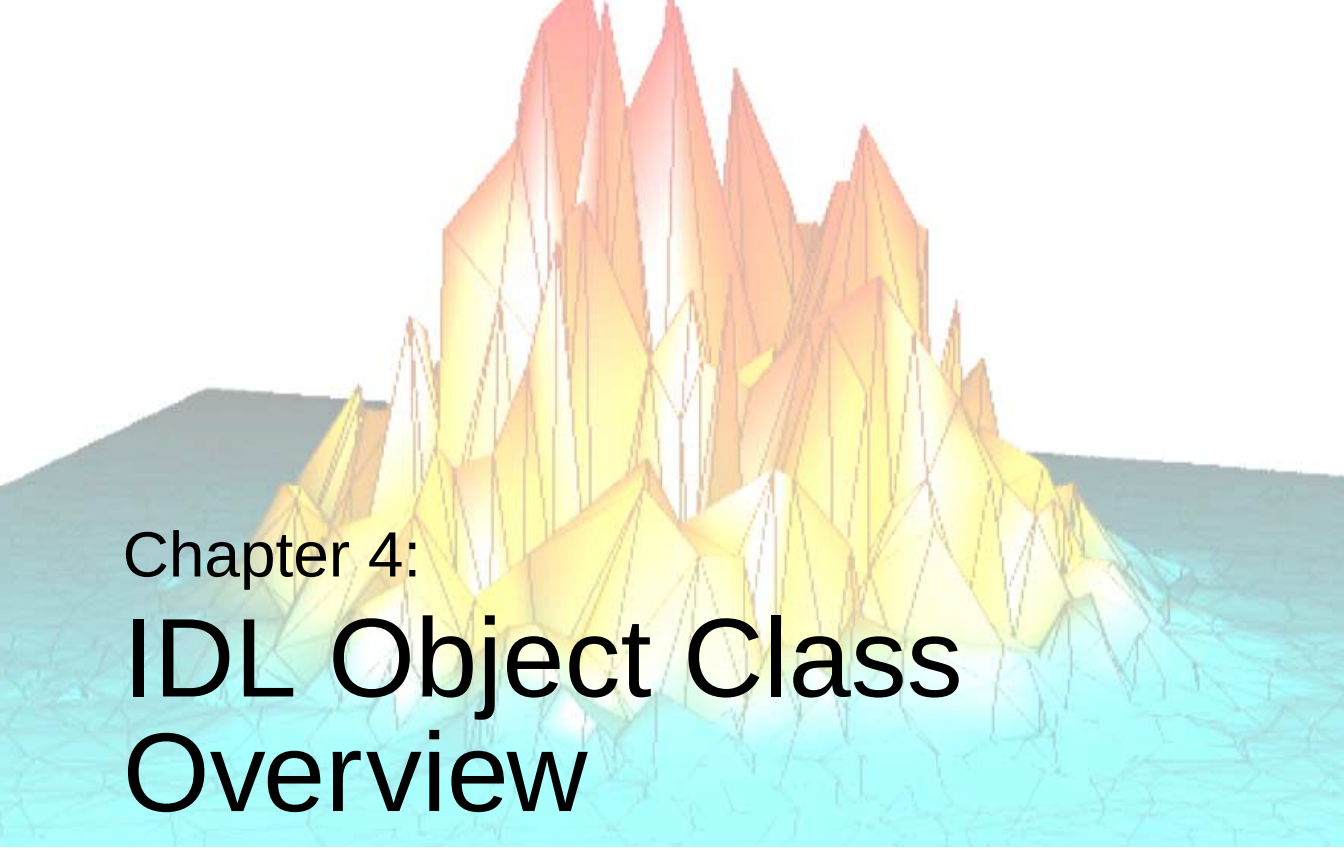
CW_ZOOM, ZOOM



# Part II: Object Class and Method Reference



# Chapter 4: IDL Object Class Overview

This section describes IDL's object class library.

# Using the Class Reference

IDL's object class library is documented in this section. The page or pages describing each class include references to any superclasses of the class, to the properties of the class, and to the methods associated with the class. Class methods are documented alphabetically following the description of the class itself.

A description of each method follows its name. Beneath the general description of the method are a number of sections that describe the Syntax for the method, its arguments (if any), its keywords (if any). These sections are described below.

## Syntax

The Syntax section shows the proper syntax for calling the method.

### Procedure Methods

IDL procedure methods have the syntax:

*Obj -> Procedure_Name*, *Argument* [, *Optional_Arguments*]

where *Obj* is a valid object reference, *Procedure_Name* is the name of the procedure method, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter to the procedure method. The square brackets around optional arguments are not used in the actual call to the procedure, they are simply used to denote the optional nature of the arguments within this document.

### Function Methods

IDL function methods have the syntax:

*Result* = *Obj -> Function_Name*(*Argument* [, *Optional_Arguments*])

where *Obj* is a valid object reference, *Result* is the returned value of the function method, *Function_Name* is the name of the function method, *Argument* is a required parameter, and *Optional_Argument* is an optional parameter. The square brackets around optional arguments are not used in the actual call to the function, they are simply used to denote the optional nature of the arguments within this document.

**Note**

All arguments and keywords to functions should be supplied *within* the parentheses that follow the function's name.

# Arguments

The *Arguments* section describes each valid argument to the method.

**Note**

These arguments are positional parameters that must be supplied in the order indicated by the method's syntax.

## Named Variables

Often, arguments that contain values upon return from the function or procedure method ("output arguments") are described as accepting "named variables." A named variable is simply a valid IDL variable name. This variable *does not* need to be defined before being used as an output argument. Note, however that when an argument calls for a named variable, only a named variable can be used—sending an expression causes an error.

## Keywords

The *Keywords* section describes each valid keyword argument to the method.

**Note**

Keyword arguments are formal parameters that can be supplied in any order.

Keyword arguments are supplied to IDL methods by including the keyword name followed by an equal sign ("=") and the value to which the keyword should be set. Note that keywords can be abbreviated to their shortest unique length. For example, the XSTYLE keyword can be abbreviated to XST.

**Note**

In the case of Init, GetProperty and SetProperty methods, keywords often correspond to object *properties*. See "Object Properties" on page 2503 for additional discussion.

## Setting Keywords

When the documentation for a keyword says something similar to, "Set this keyword to enable logarithmic plotting," the keyword is simply a switch that turns an option on and off. Usually, setting such keywords equal to 1 causes the option to be turned on. Explicitly setting the keyword to zero (or not including the keyword) turns the option off.

There is a “shortcut” that can be used to set a keyword equal to 1 without the usual syntax (i.e., `KEYWORD=1`). To “set” a keyword, simply preface it with a slash character (“/”). For example, to create a surface object with a skirt around it, set the SKIRT keyword to the SURFACE routine as follows:

```
mySurface = OBJ_NEW('IDLgrSurface', DIST(10), /SKIRT)
```

## Creating Objects from the Class Library

To create an object from the IDL object class library, use the OBJ_NEW function. See “OBJ_NEW” on page 1396. The Init method for each class describes the arguments and keywords available when you are creating a new object.

For example, to create a new object from the IDLgrAxis class, use the following call to OBJ_NEW along with the arguments and keywords accepted by the IDLgrAxis::Init method:

```
myAxis = OBJ_NEW(IDLgrAxis, DIRECTION = 1, RANGE = [0.0, 40.0])
```

# Object Properties

Some IDL objects have *properties* associated with them — things like color, line style, size, and so on. Properties are set or changed by supplying property-value pairs in a call to the object class' Init or SetProperty method:

```
Obj -> OBJ_NEW('ObjectClass', PROPERTY = value, ... )
```

*or*

```
Obj -> SetProperty, PROPERTY = value, ...
```

where *PROPERTY* is the name of a property and *value* is the associated property value.

Property values are retrieved by supplying property-value pairs in a call to the object class' GetProperty method:

```
Obj -> GetProperty, PROPERTY = variable, ...
```

where *PROPERTY* is the name of a property and *variable* is the name of an IDL variable that will hold the associated property value.

**Note**

Property-value pairs behave in exactly the same way as Keyword-value pairs. This means that you can set the value of a boolean property to 1 by preceding the name of the property with a "/" character. The following are equivalent:

```
Obj -> SetProperty, PROPERTY = 1

Obj -> SetProperty, /PROPERTY
```

If you are familiar with IDL Direct Graphics, you will note that many of the properties of IDL objects correspond to keywords to the Direct Graphics routines. Unlike IDL Direct Graphics, the IDL Object Graphics system allows you to change the value of an object's properties without re-creating the entire object. Objects must be redrawn, however, with a call to the destination object's Draw method, for the changes to become visible.

## Properties and the Property Sheet Interface

In addition to being able to set and change object property values programmatically, IDL provides a way for users to change property values via a graphical user interface. The WIDGET_PROPERTYSHEET function creates a user interface that allows users to select and change property values using the mouse and keyboard.

For an object property to be displayed in a property sheet, the property must be registered. See “Registered Properties” on page 2507 for additional discussion.

## Setting Properties at Initialization

Often, you will set an object’s properties when creating the object for the first time, which is done by specifying any keywords to the object’s Init method directly in the call of OBJ_NEW that creates the object. For example, suppose you are creating a plot and wish to use a red line to draw the plot line. You could specify the COLOR keyword to the IDLgrPlot::Init method directly in the call to OBJ_NEW:

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata, COLOR = [255, 0, 0])
```

In most cases, an object’s Init method cannot be called directly. Arguments to OBJ_NEW are passed directly to the Init method when the object is created.

For some graphics objects, you can specify a keyword that has the same meaning as an argument. In Object Graphics, the value of the keyword overrides the value set by the argument. For example,

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata, DATAX = newXData)
```

The Plot object uses the data in `newXData` for the plot’s X data.

## Setting Properties of Existing Objects

After you have created an object, you can also set its properties using the object’s SetProperty method. For example, the following two statements duplicate the single call to OBJ_NEW shown above:

```
myPlot = OBJ_NEW('IDLgrPlot', xdata, ydata)
myPlot -> SetProperty, COLOR = [255, 0, 0]
```

**Note**

Not all keywords available when the object is being initialized are necessarily available via the SetProperty method. Keywords available when using an object’s SetProperty method are noted with the word “Set” in the table included after the text description of the property.

## Retrieving Property Settings

You can retrieve the value of a particular property using an object’s GetProperty method. The GetProperty method accepts a list of keyword-variable pairs and returns

the value of the specified properties in the variables specified. For example, to return the value of the COLOR property of the plot object in our example, use the statement:

```
myPlot -> GetProperty, COLOR = plotcolor
```

The value of the COLOR property is returned in the IDL variable `plotcolor`.

You can retrieve the values of all of the properties associated with a graphics object by using the ALL keyword to the object's GetProperty method. The following statement:

```
myPlot -> GetProperty, ALL = allprops
```

returns an anonymous structure in the variable `allprops`; the structure contains the values of all of the retrievable properties of the object.

**Note**

Not all keywords available when the object is being initialized are necessarily available via the GetProperty method. Keywords available when using an object's GetProperty method are noted with the word "Get" in the table included after the text description of the property.

# About Object Property Descriptions

In the documentation for the IDL object class library, the description of each class is followed by a section describing the properties of the class. Each property description is followed by a table that looks like this:

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | Hide | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

where

- **Property Type** describes the property type associated with the property. If the property is *registered*, the property type will be one of the types described in "Registered Property Data Types" on page 2508. If the property is not registered, this field will describe the generic IDL data type of the property value.
- **Name String** is the default value of the Name property attribute. If the property is registered, this is the value that appears in the left-hand column when the property is displayed in a property sheet widget. If the property is not registered, this field will contain the words *not displayed*.

- **Get**, **Set**, and **Init** describe whether the property can be specified as a keyword to the GetProperty, SetProperty, and Init methods, respectively.
- **Registered** describes whether the property is registered for display in a property sheet widget. See “Registered Properties” on page 2507 for details on registered properties.

# Registered Properties

In order for an object property to be displayed in the WIDGET_PROPERTYSHEET interface, which makes it possible for a user to interactively change the value of the property using the mouse and keyboard, the following two conditions must be met:

- The property must belong to an object that subclasses from the IDLitComponent class. IDLitComponent provides the infrastructure necessary to display property sheets.
- The property must be *registered*. Properties that are not registered will never be displayed in a property sheet. (Note that registered properties can also be *hidden*, which prevents them from being displayed in a property sheet.)

**Note**

This section provides a brief overview of property registration. See Chapter 4, "Property Management" in the *iTool Developer's Guide* manual for a more in-depth discussion.

## Registering a Property

To register a property, use the RegisterProperty method of the IDLitComponent class:

```
Obj -> IDLitComponent::RegisterProperty, PropertyIdentifier, $
   [, TypeCode] [, ATTRIBUTE = value]
```

where *PropertyIdentifier* is a string that uniquely identifies the property, *TypeCode* is an integer between 0 and 9 specifying the property data type, and *ATTRIBUTE* is a property attribute.

Property identifier strings must obey certain rules; see "Property Identifiers" in Chapter 4 of the *iTool Developer's Guide* manual for details. Property type codes are discussed in "Registered Property Data Types" on page 2508. Property attributes are discussed in "Property Attributes" in Chapter 4 of the *iTool Developer's Guide* manual.

## Registering All Available Properties

Some of the classes in the IDL object class library include a mechanism to register all available properties in a single operation. If an object class has a REGISTER_PROPERTIES property, then setting that property to 1 when creating the object automatically registers all properties that can be registered. If a property

contains a “Yes” in the Registered box of the property description table, it will be registered automatically if the REGISTER_PROPERTIES property is set when the object is created. (See “About Object Property Descriptions” on page 2505 for a description of the property description table.)

## Registered Property Data Types

Registered properties must be of one of the data types listed in Table 4-1.

**Note**

Properties of objects that are *not* registered (that is, properties that can not appear in a property sheet) can be of any IDL data type.

| Type Code | Type | Description |
|---|---|---|
| 0 | USERDEF | User Defined properties can contain values of any IDL type, but must also include a string value that will be displayed in the property sheet. See “Property Data Types” in Chapter 4 of the *iTool Developer’s Guide* manual for additional discussion of User Defined property types. |
| 1 | BOOLEAN | Boolean properties contain either the integer 0 or the integer 1. |
| 2 | INTEGER | Integer properties contain an integer value. If a property of integer data type has a VALID_RANGE attribute that includes an increment value, the property is displayed in a property sheet using a slider. If no increment value is supplied, the property sheet allows the user to edit values manually. |
| 3 | FLOAT | Float properties contain a double-precision floating-point value. If a property of float data type has a VALID_RANGE attribute that includes an increment value, the property is displayed in a property sheet using a slider. If no increment value is supplied, the property sheet allows the user to edit values manually. |
| 4 | STRING | String properties contain a scalar string value |

*Table 4-1: iTools property data types.*

| Type Code | Type | Description |
|---|---|---|
| 5 | COLOR | Color properties contain an RGB color triple |
| 6 | LINESTYLE | Linestyle properties contain an integer value between 0 and 6, corresponding to the following IDL line styles:<br>• 0 = Solid<br>• 1 = Dotted<br>• 2 = Dashed<br>• 3 = Dash Dot<br>• 4 = Dash Dot Dot<br>• 5 = Long Dashes<br>• 6 = No Line<br>See Appendix B, "Property Controls" in the *iTool User's Guide* manual for a visual example of the available line styles. |
| 7 | SYMBOL | Symbol properties contain an integer value between 0 and 8, corresponding to the following IDL symbol types:<br>• 0 = No symbol<br>• 1 = Plus sign<br>• 2 = Asterisk<br>• 3 = Period (Dot)<br>• 4 = Diamond<br>• 5 = Triangle<br>• 6 = Square<br>• 7 = X<br>• 8 = Arrow Head<br>See Appendix B, "Property Controls" in the *iTool User's Guide* manual for a visual example of the available symbols. |

*Table 4-1: iTools property data types.*

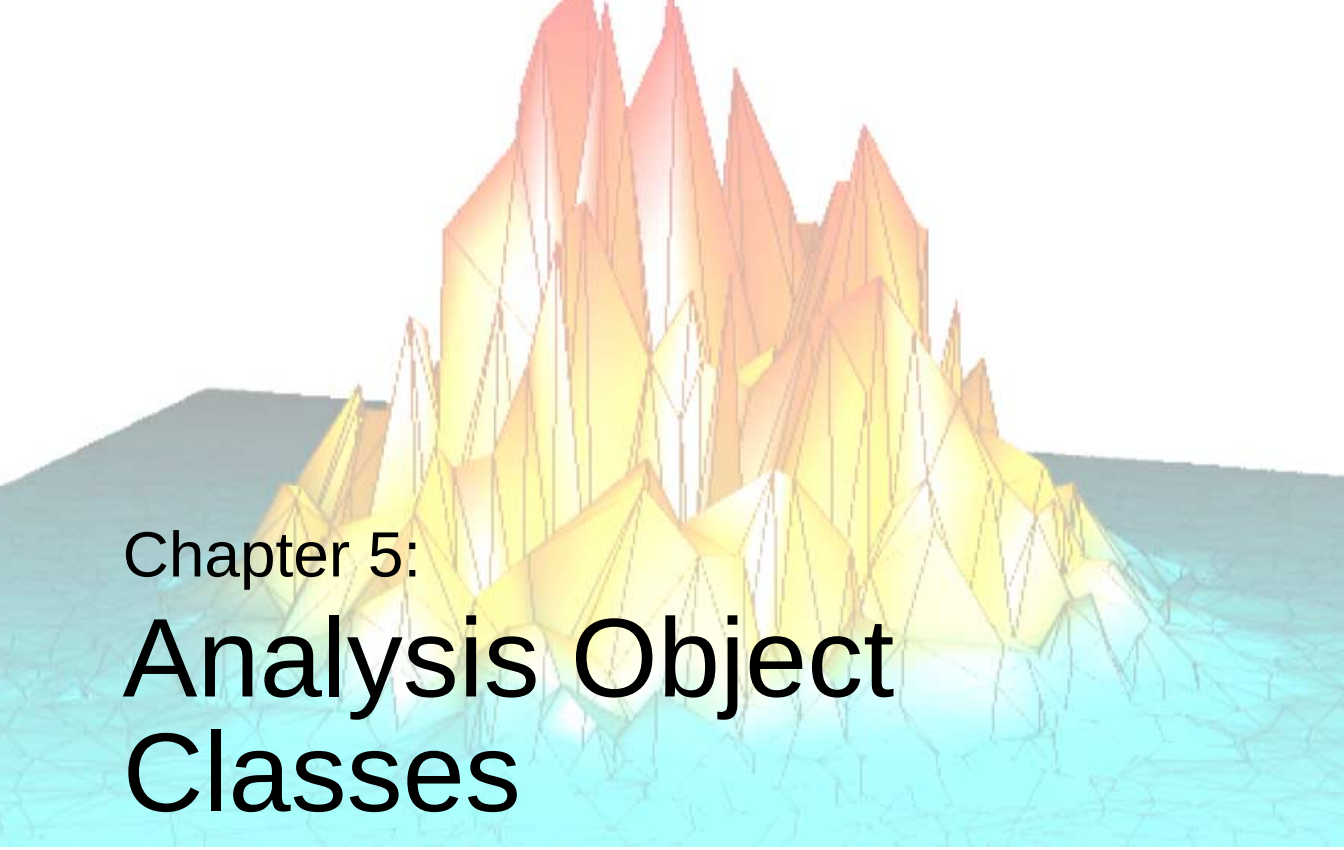
| Type Code | Type | Description |
|---|---|---|
| 8 | THICKNESS | Thickness properties contain an integer value between 1 and 10, corresponding to the thickness (in pixels) of the line. |
| 9 | ENUMLIST | Enumerated List properties contain an array of string values defined when the property is registered. The GetProperty method returns the zero-based index of the selected item. |

*Table 4-1: iTools property data types.*

# Undocumented Object Classes

Some of IDL's object classes are subclassed from more generic IDL objects. You may see references to the generic IDL objects when using IDL's HELP procedure to get information on an object, or when you use the OBJ_ISA or OBJ_CLASS functions. You may also notice that the generic objects are not documented in this section. This is not an oversight.

We have chosen not to document the workings of the more generic objects from which the IDL graphics objects are subclassed because we reserve the right to make changes to their operation. We strongly recommend that you do not use the undocumented object classes directly, or subclass your own object classes from them. RSI does not guarantee that user-written code that uses undocumented features will continue to function in future releases of IDL.



# Chapter 5: Analysis Object Classes

This chapterdescribes IDL’s built-in analysis class library.

# IDLanROI

The IDLanROI object class represents a region of interest.

**Note**

The IDLan* naming convention is used for objects in the analysis domain.

Regions of interest are described as a set of vertices that may be connected to generate a path or a polygon, or may be treated as separate points. This object may be used as a source for analytical computations on regions. (For additional information about display of ROIs in Object Graphics, refer to the IDLgrROI object class.)

## Superclasses

None

## Creation

See IDLanROI::Init.

## Properties

Objects of this class have the following properties. See “IDLanROI Properties” on page 2516 for details on individual properties.

- ALL
- BLOCK_SIZE
- DATA
- DOUBLE
- INTERIOR
- N_VERTS
- ROI_XRANGE
- ROI_YRANGE
- ROI_YRANGE
- ROI_ZRANGE
- TYPE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

The IDLanROI class has the following methods.

- IDLanROI::AppendData
- IDLanROI::Cleanup
- IDLanROI::ComputeGeometry
- IDLanROI::ComputeMask
- IDLanROI::ContainsPoints
- IDLanROI::GetProperty
- IDLanROI::Init
- IDLanROI::RemoveData
- IDLanROI::ReplaceData
- IDLanROI::Rotate
- IDLanROI::Scale
- IDLanROI::SetProperty
- IDLanROI::Translate

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.3

# IDLanROI Properties

IDLanROI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLanROI::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLanROI::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLanROI::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the state of this object. State information about the object includes things like block size, type, etc., but not vertex data.

**Note**

The fields in this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## BLOCK_SIZE

The number of vertices to allocate per block as needed for the region. When additional vertices are required, an additional block is allocated. The default is 100.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DATA

A *2 x n* or a *3 x n* array that defines the 2-D or 3-D vertex data, respectively. DATA is equivalent to the optional arguments, X, Y, and Z. This property is stored as double

precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is stored as single precision floating point.

| **Property Type** | Array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DOUBLE

A non-zero value that indicates whether or not data should be stored in this object in double precision floating point. Set this keyword to zero to indicate that the data should be stored in single precision floating point, which is the default. The DOUBLE property controls the precision used for storing the data in the AppendData, Init, and ReplaceData methods via the X, Y, and Z arguments and in SetProperty method via the DATA keyword. IDL converts any data already stored in the object to the requested precision, if necessary. Note that this keyword does not need to be set if any of the X, Y, or Z arguments or the DATA parameters are of type DOUBLE. However, setting this keyword may be desirable if the data consists of large integers that cannot be accurately represented in single precision floating point. This property is also automatically set to one if any of the X, Y or Z arguments or the DATA parameter is stored using a variable of type DOUBLE.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## INTERIOR

A Boolean variable that marks this region as an interior region (i.e., a region treated as a hole). By default, the region is treated as an exterior region.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## N_VERTS

An integer that contains the number of vertices currently being used by the region.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ROI_XRANGE

A two-element double-precision floating-point vector of the form [*xmin, xmax*] that specifies the range of X data coordinates covered by the region.

| | | | |
|---|---|---|---|
| **Property Type** | Vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ROI_YRANGE

A two-element double-precision floating-point vector of the form [*ymin, ymax*] specifying the range of Y data coordinates covered by the region.

| | | | |
|---|---|---|---|
| **Property Type** | Vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ROI_ZRANGE

A two-element double-precision floating-point vector of the form [*zmin, zmax*] specifying the range of Z data coordinates covered by the region.

| | | | |
|---|---|---|---|
| **Property Type** | Vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## TYPE

An integer that indicates the type of the region. The TYPE keyword determines how computational operations, such as mask generation, are performed. Valid values include:

- 0 = points
- 1 = path
- 2 = closed polygon (the default)

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLanROI::AppendData

The IDLanROI::AppendData procedure method appends vertices to the region.

## Syntax

*Obj* -> [IDLanROI::]AppendData, *X* [, *Y*] [, *Z*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

## Arguments

### X

A vector providing the X components of the vertices to be appended. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2,*] or [3,*]), in which case, X[0,*] represents the X values, X[1,*] represents the Y values, and X[2,*] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

### Y

A vector providing the Y components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

### Z

A vector providing the Z components of the vertices to be appended. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

# Keywords

## XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin, xmax*], representing the *X* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

## YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin, ymax*], representing the *Y* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

## ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin, zmax*], representing the *Z* range of the modification to the region. The reported range accounts for the last vertex in the region before the append occurred, as well as all vertices appended. This data is returned in double-precision floating-point.

# Version History

Introduced: 5.3

# IDLanROI::Cleanup

The IDLanROI::Cleanup procedure method performs all cleanup for a region of interest object.

**Note**

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLanROI::]Cleanup (In a subclass' Cleanup method only)

## Arguments

None.

## Keywords

None.

## Version History

Introduced: 5.3

# IDLanROI::ComputeGeometry

The IDLanROI::ComputeGeometry function method computes the geometrical values for area, perimeter, and/or centroid of the region.

## Syntax

*Result* = *Obj* `->` [IDLanROI::]ComputeGeometry( [, AREA=*variable*] [, CENTROID=*variable*] [, PERIMETER=*variable*] [, SPATIAL_OFFSET=*vector*] [, SPATIAL_SCALE=*vector*] )

## Return Value

### Result

This function method returns a 1 for success, or a 0 for failure. Each computed value is returned in the *variable* name assigned to each keyword.

## Arguments

None.

## Keywords

### AREA

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the area of the region. Interior regions (holes) return a negative area.

Note that the computed area represents the geometric area described by the region's vertex data. A pixel-based area can be computed as follows:

1. Compute a mask for the region.

```
mask = oROI -> ComputeMask()
```

2. Call IMAGE_STATISTICS to count number of samples within the mask.

```
IMAGE_STATISTICS, myImage, MASK = mask, COUNT = nSamples
```

3. Compute pixel area.

```
pixelArea = nSamples * pixelXSize * pixelYSize
```

### CENTROID

Set this keyword to a named variable that upon return contains a double-precision floating-point vector [*x*,*y*,*z*] representing the centroid for the region. If the TYPE of the region is 0 (points), the centroid is computed as the average of each of the vertices in the region. If the TYPE of the region is 1 (path), the centroid is computed as the weighted average of each of the midpoints of the lines in the region. Weights are proportional to the length of the lines. If the TYPE of the region is 2 (polygon), the centroid is computed as a weighted average of the centroids of the polygons making up the ROI (interior centroids use negative weights). Weights are proportional to the polygon area.

### PERIMETER

Set this keyword to a named variable that upon return contains a double-precision floating-point value representing the perimeter of the region.

### SPATIAL_OFFSET

Set this keyword to a two or three-element vector, [*tx*, *ty*] or [*tx*, *ty, tz*], representing the spatial calibration offset factors to be applied for the geometry calculations. The value of SPATIAL_SCALE is applied before the spatial offset values are applied. The default is [0.0, 0.0, 0.0]. IDL converts and maintains this value in double-precision floating-point.

### SPATIAL_SCALE

Set this keyword to a two or three-element vector, [*sx*, *sy*] or [*sx*, *sy, sz*], representing the spatial calibration scaling factors to be applied for the geometry calculations. The spatial calibration scale is applied first, then the value of SPATIAL_OFFSET is applied. The default is [1.0, 1.0, 1.0]. IDL converts and maintains this value in double-precision floating-point.

## Version History

Introduced: 5.3

# IDLanROI::ComputeMask

The IDLanROI::ComputeMask function method prepares a two-dimensional mask for the region.

## Syntax

*Result* = *Obj* -> [IDLanROI::]ComputeMask( [, INITIALIZE={ –1 | 0 | 1 }] [, DIMENSIONS=*[xdim, ydim]*] | [, MASK_IN=*array*] [, LOCATION=*[x, y* [, *z]]*] [, MASK_RULE={ 0 | 1 | 2 }] [, PIXEL_CENTER=*[x, y]*] [, PLANE_NORMAL=*[x, y, z]*] [, PLANE_XAXIS=*[x,y,z]*] [, /RUN_LENGTH] )

## Return Value

### Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = \mathrm{MAX}(\mathrm{MIN}(255, (M_{\mathrm{roi}} * Ext) + M_{\mathrm{in}}), 0)$$

where $M_{\mathrm{roi}}$ is 255 and *Ext* is 1 for points within an exterior region and –1 for points within an interior region.

If the TYPE of the region is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the region is 1 (path), one-pixel-wide line segments are set within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a region, and the pixel falls within the region (according to the MASK_RULE).

## Arguments

None.

# Keywords

## DIMENSIONS

Set this keyword to a two-element vector, [*xdim*, *ydim*], specifying the requested dimensions of the returned mask. If MASK_IN is provided, the value of this keyword is ignored and the dimensions of that mask are used. Otherwise, the default dimensions are [100, 100].

## INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- –1 = The mask is not initialized. This option is useful when updating an already existing mask. This is the default if the MASK_IN keyword is set.
- 0 = The mask is initialized so that each pixel is set to 0. This is the default if the MASK_IN keyword is not set.
- 1 = The mask is initialized so that each pixel is set to 255.

## LOCATION

Set this keyword to a vector of the form [*X*, *Y*[, *Z*]] specifying the location of the origin of the mask. The default is [0, 0, 0]. IDL converts and maintains this value in double-precision floating-point.

## MASK_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type BYTE and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the DIMENSIONS keyword.

### MASK_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- 0 = Boundary only. All pixels falling on a region's boundary are set.
- 1 = Interior only. All pixels falling within the region's boundary, but not on the boundary, are set.
- 2 = Boundary + Interior. All pixels falling on or within a region's boundary are set.

### PIXEL_CENTER

Set this keyword to a 2-element vector, [*x*, *y*], to indicate where the lower-left mask pixel is to centered relative to a Cartesian grid. The default value is [0.0, 0.0], indicating that the lower-left pixel is centered at [0.0, 0.0].

### PLANE_NORMAL

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the normal vector for the plane on which the mask is to be computed. The default is [0, 0, 1].

### PLANE_XAXIS

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is [1, 0, 0].

### RUN_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

## Version History

Introduced: 5.3

RUN_LENGTH keyword: 5.6

# IDLanROI::ContainsPoints

The IDLanROI::ContainsPoints function method determines whether the given data coordinates are contained within the closed polygon region.

## Syntax

*Result* = *Obj* -> [IDLanROI::]ContainsPoints( *X* [, *Y* [, *Z*]] )

## Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly out of bounds of the ROI.
- 1 = Interior. The point lies strictly inside the bounds of the ROI.
- 2 = On edge. The point lies on an edge of the ROI boundary.
- 3 = On vertex. The point matches a vertex of the ROI.

A point is considered to be exterior if:

- the point falls within the boundary of an interior region (hole).
- the point does not lie in the plane of the region.
- the region TYPE property is set to 0 (points) or 1 (path).

## Arguments

### X

A vector providing the *X* components of the points to be tested. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values.

### Y

A vector providing the *Y* components of the points to be tested.

### Z

A scalar or vector providing the *Z* component(s) of the points to be tested. If not provided, the *Z* components default to 0.0.

## Keywords

None.

## Version History

Introduced: 5.3

# IDLanROI::GetProperty

The IDLanROI::GetProperty procedure method retrieves the value of a property or group of properties for the region.

## Syntax

*Obj* -> [IDLanROI::]GetProperty [, ALL=*variable*] [, N_VERTS=*variable*] [, ROI_XRANGE=*variable*] [, ROI_YRANGE=*variable*] [, ROI_ZRANGE=*variable*]

## Arguments

None.

## Keywords

Any property listed under “IDLanROI Properties” on page 2516 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 5.3

# IDLanROI::Init

The IDLanROI::Init function method initializes a region of interest object.

**Note**

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW( 'IDLanROI' [, *X* [, *Y* [, *Z* ]]] [, BLOCKSIZE{Get, Set}=*vertices*] [, DATA{Get, Set}=*array*] [, /DOUBLE{Get, Set}] [, /INTERIOR{Get, Set}] [, TYPE{Get}={ 0 | 1 | 2 }] )

or

*Result* = *Obj* -> [IDLanROI::]Init( [*X* [, *Y* [, *Z* ]]] ) (*Only in a subclass' Init method.*)

**Note**

Keywords can be used in either form. They are omitted in the second form for brevity.

## Arguments

### X

A vector providing the *X* components of the vertices for the region. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

### Y

A vector providing the *Y* components of the vertices. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

### Z

A scalar or vector providing the *Z* component(s) of the vertices. If not provided, *Z* values default to 0.0. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise, it is converted to single-precision floating-point.

## Keywords

Any property listed under “IDLanROI Properties” on page 2516 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.3

# IDLanROI::RemoveData

The IDLanROI::RemoveData procedure method removes vertices from the region.

## Syntax

*Obj* -> [IDLanROI::]RemoveData[, COUNT=*vertices*] [, START=*index*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

## Arguments

None.

## Keywords

### COUNT

Set this keyword to the number of vertices to remove. The default is one vertex.

### START

Set this keyword to an index (into the region's current vertex list) where the removal is to begin. By default, the final vertex is removed.

### XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin, xmax*], that represents the *X* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

### YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin, ymax*], that represents the *Y* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

### ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin*, *zmax*], that represents the *Z* range of the modification to the region. The reported range accounts for the vertex just before the removal (if any), the vertex just after the removal (if any), and the removed vertices. This data is returned in double-precision floating-point.

## Version History

Introduced: 5.3

# IDLanROI::ReplaceData

The IDLanROI::ReplaceData procedure method replaces vertices in the region with alternate values. The number of replacement values need not match the number of values being replaced.

## Syntax

*Obj* -> [IDLanROI::]ReplaceData, *X*[, *Y*[, *Z*]] [, START=*index*] [, FINISH=*index*] [, XRANGE=*variable*] [, YRANGE=*variable*] [, ZRANGE=*variable*]

## Arguments

### X

A vector providing the X components of the new replacement vertices. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimensions either 2 or 3 ([2, *] or [3, *]), in which case, X[0, *] represents the X values, X[1, *] represents the Y values, and X[2, *] represents the Z values. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

### Y

A vector providing the Y components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

### Z

A vector providing the Z components of the new replacement vertices. If the DOUBLE property is non-zero, the data is converted to double precision and is appended to the existing double precision data. Otherwise it is converted to single precision floating point and appended to the existing single precision data.

# Keywords

## FINISH

Set this keyword to the index of the region's current subregion vertex list where the replacement ends. If the START keyword value is ≥ 0, the default FINISH is given by

FINISH = ((START + N_NEW – 1) MOD N_OLD)

where N_NEW is the number of replacement vertices provided via the [*X*, *Y*, *Z*] arguments and N_OLD is the number of vertices (prior to replacement) in the current subregion.

If the START keyword is not set or is negative, the default FINISH is given by

FINISH = N_OLD – 1

FINISH may be less than START in which case the vertices, including and following START and the vertices preceding and including FINISH, are replaced with the new values.

## START

Set this keyword to an index of the region's current subregion vertex list where the replacement begins. If the FINISH keyword value is ≥ 0, the default START is given by

START = ((FINISH – N_NEW + 1) MOD N_OLD)

where N_NEW is the number of replacement vertices provided via the [*X*, *Y*, *Z*] arguments and N_OLD is the number of vertices (prior to replacement) in the current subregion.

If the FINISH keyword is not set (or negative), the default START is clamped to 0 and is given by

N_OLD – N_NEW

## XRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*xmin*, *xmax*], representing the *X* range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

### YRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*ymin, ymax*], representing the *Y* range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

### ZRANGE

Set this keyword to a named variable that upon return contains a two-element vector, [*zmin, zmax*], representing the *Z* range of the modification to the region. The reported range accounts for the replaced vertices, the vertex just before the replacement (if any), the vertex just after the replacement (if any), and the new replacement vertices. This data is returned in double-precision floating-point.

## Version History

Introduced: 5.3

# IDLanROI::Rotate

The IDLanROI::Rotate procedure method modifies the vertices for the region by applying a rotation.

## Syntax

*Obj* -> [IDLanROI::]Rotate, *Axis*, *Angle* [, CENTER=*[x, y*[, *z*]*]*]

## Arguments

### Axis

A three-element vector of the form [*x, y, z*] describing the axis about which the region is to be rotated.

### Angle

The angle, measured in degrees, by which the rotation is to occur.

## Keywords

### CENTER

Set this keyword to a two or three-element vector of the form [*x, y*], or [*x, y, z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

## Version History

Introduced: 5.3

# IDLanROI::Scale

The IDLanROI::Scale procedure method modifies the vertices for the region by applying a scale.

## Syntax

*Obj* -> [IDLanROI::]Scale, *Sx*[, *Sy*[, *Sz*]]

## Arguments

### Sx

The *X* scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in *X*, *Sx*[1] represents the scale in *Y*, *Sx*[2] represents the scale in *Z*. IDL converts and applies this data in double-precision floating-point.

### Sy

The *Y* scale factor. IDL converts and applies this data in double-precision floating-point.

### Sz

The *Z* scale factor. IDL converts and applies this data in double-precision floating-point.

## Keywords

None.

## Version History

Introduced: 5.3

# IDLanROI::SetProperty

The IDLanROI::SetProperty procedure method sets the value of a property or group of properties for the region.

## Syntax

*Obj* -> [IDLanROI::]SetProperty

## Arguments

None.

## Keywords

Any property listed under “IDLanROI Properties” on page 2516 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.3

# IDLanROI::Translate

The IDLanROI::Translate procedure method modifies the vertices for the region by applying a translation.

## Syntax

*Obj* -> [IDLanROI::]Translate, *Tx*[, *Ty*[, *Tz*]]

## Arguments

### Tx

The X translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in *X*, *Tx*[1] represents translation in *Y*, *Tx*[2] represents translation in *Z*. IDL converts and applies this data in double-precision floating-point.

### Ty

The *Y* translation factor. IDL converts and applies this data in double-precision floating-point.

### Tz

The *Z* translation factor. IDL converts and applies this data in double-precision floating-point.

## Keywords

None.

## Version History

Introduced: 5.3

# IDLanROIGroup

The IDLanROIGroup object class is an analytical representation of a group of regions of interest.

## Superclasses

This class is a subclass of TrackBall.

## Creation

See IDLanROIGroup::Init.

## Properties

Objects of this class have the following properties. See “IDLanROIGroup Properties” on page 2544 for details on individual properties.

- ALL
- ROIGROUP_XRANGE
- ROIGROUP_YRANGE
- ROIGROUP_ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

The IDLanROIGroup class has the following methods:

- IDLanROIGroup::Add
- IDLanROIGroup::Cleanup
- IDLanROIGroup::ComputeMask
- IDLanROIGroup::ComputeMesh
- IDLanROIGroup::ContainsPoints
- IDLanROIGroup::GetProperty
- IDLanROIGroup::Init
- IDLanROIGroup::Rotate

- IDLanROIGroup::Scale
- IDLanROIGroup::Translate

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.3

# IDLanROIGroup Properties

IDLanROIGroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via “IDLanROIGroup::GetProperty” on page 2555. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via “IDLanROIGroup::Init” on page 2556.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure with the values of all of the properties associated with the state of this object.

**Note**

The fields in this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ROIGROUP_XRANGE

A two-element double-precision floating-point vector of the form [*xmin, xmax*] specifying the range of X data coordinates covered by the region.

| **Property Type** | Vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ROIGROUP_YRANGE

A two-element double-precision floating-point vector of the form [*ymin, ymax*] specifying the range of Y data coordinates covered by the region.

| | | | |
|---|---|---|---|
| **Property Type** | Vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ROIGROUP_ZRANGE

A two-element double-precision floating-point vector of the form [*zmin, zmax*] specifying the range of Z data coordinates covered by the region.

| | | | |
|---|---|---|---|
| **Property Type** | Vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLanROIGroup::Add

The IDLanROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLanROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

## Syntax

*Obj* -> [IDLanROIGroup::]Add, *ROI*

## Arguments

### ROI

A reference to an instance of the IDLanROI object class representing the region of interest to be added to the group.

## Keywords

Accepts all keywords accepted by the IDL_Container::Add method.

## Version History

Introduced: 5.3

# IDLanROIGroup::Cleanup

The IDLanROIGroup::Cleanup procedure method performs all cleanup for a region of interest group object.

**Note**

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLanROIGroup::]Cleanup (In a subclass' Cleanup method only.)

## Arguments

None.

## Keywords

None.

## Version History

Introduced: 5.3

# IDLanROIGroup::ComputeMask

The IDLanROIGroup::ComputeMask function method prepares a two-dimensional mask for this group of regions.

# Syntax

*Result* = *Obj* -> [IDLanROIGroup::]ComputeMask( [, INITIALIZE={ -1 | 0 | 1 }] [, DIMENSIONS=*[xdim, ydim]*] | [, MASK_IN=*array*] [, LOCATION=*[x, y* [, *z]]*] [, MASK_RULE={ 0 | 1 | 2 }] [, /RUN_LENGTH] )

# Return Value

## Result

The return value is a two-dimensional array of bytes whose values range from 0 to 255. The mask is computed by applying the following formula to the current mask for each mask point contained within the ROI:

$$M_{out} = \text{MAX}(\text{MIN}(0, (M_{roi} * Ext) + M_{in}), 255)$$

where $M_{roi}$ is 255 and *Ext* is 1 for points within an exterior region and –1 for points within an interior region.

If the TYPE of the contained regions is 0 (points), a single mask pixel is set for each region vertex that falls within the bounds of the mask.

If the TYPE of the contained regions is 1 (path), each pixel along the paths of the regions is set if it falls within the mask.

If the TYPE of the region is 2 (closed polygon), a mask pixel is set if that pixel is on the plane of a contained region, and the pixel falls within that region (according to the MASK_RULE).

# Arguments

None.

# Keywords

## DIMENSIONS

Set this keyword to a two-element vector, [*xdim*, *ydim*], specifying the requested dimensions of the returned mask. If MASK_IN is provided, the value of this keyword

is ignored, and the dimensions of that mask are used. Otherwise, the default dimensions are [100, 100].

## INITIALIZE

Set this keyword to indicate how the mask should be initialized. Valid values include:

- –1 = The mask is not initialized; the default if the MASK_IN keyword is set. This option is useful when updating an already existing mask.
- 0 = The mask is initialized with each pixel set to 0; the default if the MASK_IN keyword is not set.
- 1 = The mask is initialized with each pixel set to 255.

## LOCATION

Set this keyword to a vector of the form [*X, Y*[, *Z*]] specifying the location of the origin of the mask. The default is [0, 0, 0].

## MASK_IN

Set this keyword to a two-dimensional array representing a mask that is already allocated and to be updated for this region. If the variable specified by this keyword is of type BYTE and is also specified as the function result, then this method updates the mask data in-place without copying. If this keyword is not provided, a mask is allocated by default to match the dimensions specified via the DIMENSIONS keyword.

## MASK_RULE

Set this keyword to an integer specifying the rule used to determine whether a given pixel should be set within the mask. Valid values include:

- 0 = Boundary Only. All pixels falling on a region’s boundary are set.
- 1 = Interior Only. All pixels falling within the region’s boundary, but not on the boundary, are set.
- 2 = Boundary + Interior. All pixels falling on or within a region’s boundary are set.

## PLANE_NORMAL

Set this keyword to a three-element vector, [*x, y, z*], specifying the normal vector for the plane on which the mask is to be computed. The default is [0, 0, 1].

### PLANE_XAXIS

Set this keyword to a three-element vector, [*x*, *y*, *z*], specifying the direction vector along which each row of mask pixels is to be computed (starting at LOCATION). The default is [1, 0, 0].

### RUN_LENGTH

Set this keyword to a non-zero value to return a run-length encoded representation of the mask, stored in a one-dimensional unsigned long array. When run-length encoded, each element with an even subscript contains the length of the run, and the following element contains the starting index of the run.

## Version History

Introduced: 5.3

RUN_LENGTH keyword: 5.6

# IDLanROIGroup::ComputeMesh

The IDLanROIGroup::ComputeMesh function method triangulates a surface mesh with optional capping from the stack of regions contained within this group.

**Note**

The contained regions may be concave. However, this method will fail under the following conditions:

- The region group contains fewer than two regions.
- The TYPE property of the contained regions is 0 (points) or 1 (path).
- Any of the contained regions are not simple (i.e., a region is self-intersecting).
- The region group contains interior regions (holes).
- More than one region lies on the same plane (i.e., the region group contains branches).

Each region pair is normalized by perimeter and the triangulation is computed by walking the contours in parallel, keeping the normalized progress along each contour in sync. The returned triangulation minimizes the mesh surface area. Each vertex may appear only once in the output, and the resulting polygon mesh is solid with outward facing normals computed via the right-hand rule. If capping is requested, it is computed using the IDLgrTessellator on the top and bottom regions, and/or the regions on either side of an inter-slice gap.

# Syntax

*Result* = *Obj*->[IDLanROIGroup::]ComputeMesh( *Vertices*, *Conn* [, CAPPED={ 0 | 1 | 2}] [, SURFACE_AREA=*variable*] )

# Return Value

## Result

The return value of this function method is the number of triangles generated if the surface mesh triangulation is successful, or zero if unsuccessful.

# Arguments

## Vertices

An output [3, n] array of vertices. If all regions in the group are defined with single precision vertices (DOUBLE property is zero), then IDL returns a single precision floating point array. Otherwise, if any of the regions in the group are defined with double precision vertices (DOUBLE property is non-zero), then IDL returns a double precision floating point array.

## Conn

An output polygon mesh connectivity array.

# Keywords

## CAPPED

Set this keyword to a value to indicate whether flat caps are to be computed at the top-most or bottom-most regions (as selected by a counter-clockwise rule), or at the regions on either side of an inter-slice gap. The value of this keyword is a bit-wise OR of the values shown below. For example, to cap the top-most and bottom-most regions only, set the CAPPED keyword to 3. The default is 0 (no caps).

- 0 = no caps
- 1 = cap the top-most region
- 2 = cap the bottom-most region

## SURFACE_AREA

Set this keyword to a named variable that upon return contains the overall surface area of the computed triangulation. This value was minimized in the computation of the triangulation. IDL returns this value in a double-precision floating-point variable.

# Version History

Introduced: 5.3

# IDLanROIGroup::ContainsPoints

The IDLanROIGroup::ContainsPoints function method determines whether the given points (in data coordinates) are contained within this region group.

The regions within this group must have a TYPE of 2 (closed polygon) and must fall on parallel planes for successful containment testing to occur.

For each point to be tested:

- If the point lies directly on one of the region planes, it is tested for containment within each of the regions that fall on that plane.
- If the point lies between two of the region planes, it is projected onto the nearest region plane, and tested for containment within each of the regions on that plane.
- If the point lies above or below the stack of parallel region planes, the point will be considered to be exterior to the region group.

On a given plane, a point will be considered to be exterior if either of the following conditions are true:

- The point does not fall within any of the regions on that plane.
- The point falls within as many or more holes than non-hole regions on that plane.

## Syntax

*Result* = *Obj* `->` [IDLanROIGroup::]ContainsPoints( *X*[, *Y*[, *Z*]] )

## Return Value

The return value is a vector of values, one per provided point, indicating whether that point is contained. Valid values within this return vector include:

- 0 = Exterior. The point lies strictly outside the bounds of the ROI.
- 1 = Interior. The point lies strictly inside the bounds of the ROI.
- 2 = On Edge. The point lies on an edge of the ROI boundary.
- 3 = On Vertex. The point matches a vertex of the ROI.

# Arguments

## X

A vector providing the *X* components of the points to be tested. If the *Y* and *Z* arguments are not specified, *X* must be a two-dimensional array with the leading dimension either 2 or 3 ([2,*] or [3,*]), in which case, *X*[0,*] represents the *X* values, *X*[1,*] represents the *Y* values, and *X*[2,*] represents the *Z* values.

## Y

A vector providing the *Y* components of the points to be tested.

## Z

A scalar or vector providing the *Z* components of the points to be tested. If not provided, the *Z* components default to 0.0.

# Keywords

None.

# Version History

Introduced: 5.3

# IDLanROIGroup::GetProperty

The IDLanROIGroup::Get Property procedure method retrieves the value of a property or group of properties for the region group.

## Syntax

*Obj* -> [IDLanROIGroup::]GetProperty[, ALL=*variable*]
[, ROIGROUP_XRANGE=*variable*] [, ROIGROUP_YRANGE=*variable*]
[, ROIGROUP_ZRANGE=*variable*]

## Arguments

None.

## Keywords

Any property listed under “IDLanROIGroup Properties” on page 2544 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 5.3

# IDLanROIGroup::Init

The IDLanROIGroup::Init function method initializes a region of interest group object.

**Note**

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLanROIGroup')

or

*Result* = *Obj* -> [IDLanROIGroup::]Init( ) (*Only in a subclass' Init method*.)

## Arguments

None.

## Keywords

Any property listed under "IDLanROIGroup Properties" on page 2544 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.3

# IDLanROIGroup::Rotate

The IDLanROIGroup::Rotate procedure method modifies the vertices for all regions within the group by applying a rotation.

## Syntax

*Obj* -> [IDLanROIGroup::]Rotate, *Axis*, *Angle*[, CENTER=*[ x, y*[, *z* ]*]* ]

## Arguments

### Axis

A three-element vector of the form [*x, y, z*] describing the axis about which the region group is to be rotated.

### Angle

The angle, measured in degrees, by which to rotate the ROI group.

## Keywords

### CENTER

Set this keyword to a two or three-element vector of the form [*x, y*], or [*x, y, z*] specifying the center of rotation. The default is [0, 0, 0]. IDL converts and applies this data in double-precision floating-point.

## Version History

Introduced: 5.3

# IDLanROIGroup::Scale

The IDLanROIGroup::Scale procedure method modifies the vertices for the region by applying a scale.

## Syntax

*Obj* -> [IDLanROIGroup::]Scale, *Sx*[, *Sy*[, *Sz*]]

## Arguments

### Sx

The *X* scale factor. If the *Sy* and *Sz* arguments are not specified, *Sx* must be a two or three-element vector, in which case *Sx*[0] represents the scale in *X*, *Sx*[1] represents the scale in *Y*, *Sx*[2] represents the scale in *Z*. IDL converts and applies this data in double-precision floating-point.

### Sy

The *Y* scale factor. IDL converts and applies this data in double-precision floating-point.

### Sz

The *Z* scale factor. IDL converts and applies this data in double-precision floating-point.

## Keywords

None.

## Version History

Introduced: 5.3

# IDLanROIGroup::Translate

The IDLanROIGroup::Translate procedure method modifies the vertices of all regions within the group by applying a translation.

## Syntax

*Obj* -> [IDLanROIGroup::]Translate, *Tx*[, *Ty*[, *Tz*]]

## Arguments

### Tx

The *X* translation factor. If the *Ty* and *Tz* arguments are not specified, *Tx* must be a two or three-element vector, in which case *Tx*[0] represents translation in *X*, *Tx*[1] represents translation in *Y, Tx*[2] represents translation in *Z*. IDL converts and applies this data in double-precision floating-point.

### Ty

The *Y* translation factor. IDL converts and applies this data in double-precision floating-point.

### Tz

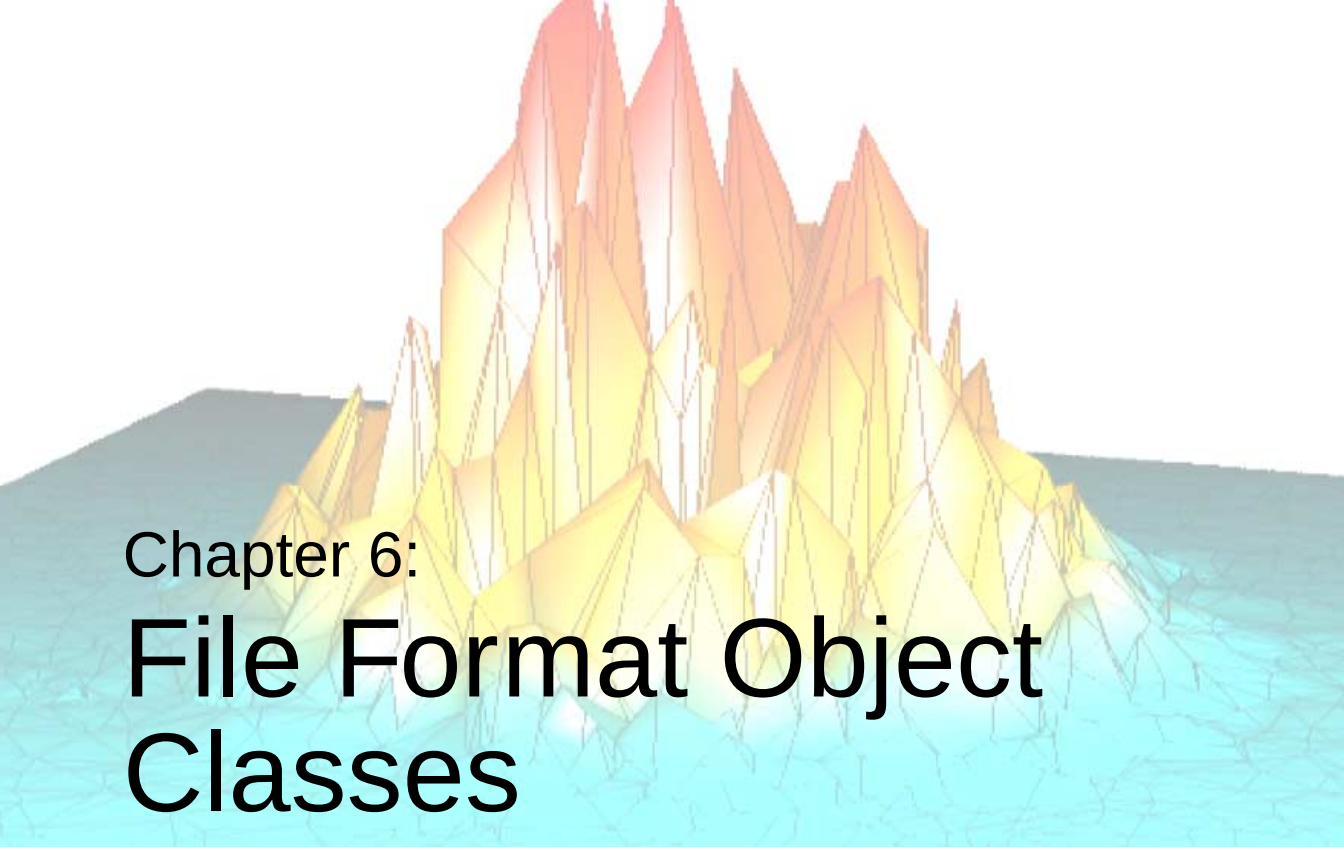
The *Z* translation factor. IDL converts and applies this data in double-precision floating-point.

## Keywords

None.

## Version History

Introduced: 5.3



# Chapter 6: File Format Object Classes

This chapter describes IDL's built-in file format class library.

# IDLffDICOM

An IDLffDICOM object contains the data for one or more images embedded in a DICOM Part 10 file. The API to the IDLffDICOM object provides accessor methods to the basic data elements of a DICOM file, namely the group/element tag, value representation, length, and data values. Additional methods deal with the file header preamble, data dictionary description for individual elements, and embedded sequences of elements. Most methods take a DICOM group/element tag as a parameter. An alternative parameter to the DICOM tag in some methods is the reference. A reference value is a LONG integer that is unique to each element in the DICOM object. This value can be used to directly access a specific element and to differentiate between elements in the DICOM file that have the same group/element tag. Valid reference values are always positive.

See "IDL DICOM v3.0 Conformance Summary" on page 2564 for information regarding IDL DICOM file reading support.

## Superclasses

This class has no superclasses.

## Creation

See "IDLffDICOM::Init" on page 2591.

## Properties

Objects of this class have the following properties. See "IDLffDICOM Properties" on page 2568 for details on individual properties.

- VERBOSE

## Methods

This class has the following methods:

- IDLffDICOM::Cleanup
- IDLffDICOM::DumpElements
- IDLffDICOM::GetChildren
- IDLffDICOM::GetDescription

- IDLffDICOM::GetElement
- IDLffDICOM::GetGroup
- IDLffDICOM::GetLength
- IDLffDICOM::GetParent
- IDLffDICOM::GetPreamble
- IDLffDICOM::GetReference
- IDLffDICOM::GetValue
- IDLffDICOM::GetVR
- IDLffDICOM::Init
- IDLffDICOM::Read
- IDLffDICOM::Reset

## Version History

Introduced: 5.2

# IDL DICOM v3.0 Conformance Summary

## Introduction

This section is an abbreviated DICOM conformance statement for IDL, and specifies the compliance of RSI IDL DICOM file reading support to the DICOM v3.0 standard. As described in the DICOM Standard PS 3.2 (Conformance), the purpose of this document is to outline the level of conformance to the DICOM standard and to enumerate the supported DICOM Service Classes, Information Objects, and Communications Protocols supported by this implementation.

IDL does not contain or support any of the DICOM services such as Storage, Query/Retrieve, Print, Verification, etc., so there will be no conformance claims relating to these services and no mention of any Application Entities for these services. Communications Protocol profiles will also be absent from this document for the same reasons. The remainder of this document will describe how IDL handles the various Information Objects it is capable of reading.

## Reading of DICOM Part 10 files

IDL supports reading files that conform to the DICOM Standard PS 3.10 DICOM File Format. This format provides a means to encapsulate in a file the Data Set representing a SOP (Service Object Pair) Instance related to a DICOM IOD (Information Object Definition). Files written to disk in this DICOM File Format will be referred to as DICOM Part 10 files for the remainder of this document. Note that IDL does NOT support the writing of files in this DICOM File Format, only reading.

## Encapsulated Transfer Syntaxes Supported

IDL supports reading DICOM Part 10 files whose contents have been written using the following Transfer Syntaxes. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

| UID Value | UID Name |
|---|---|
| 1.2.840.10008.1.2 | Implicit VR Little Endian: Default Transfer Syntax for DICOM |
| 1.2.840.10008.1.2.1 | Explicit VR Little Endian |
| 1.2.840.10008.1.2.2 | Explicit VR Big Endian |

*Table 0-1: Encapsulated Transfer Syntaxes Supported*

## Encapsulated Transfer Syntaxes NOT Supported

IDL does NOT support reading DICOM Part 10 files whose contents have compressed data that has been written using the following Transfer Syntaxes. IDL will NOT be able to access the data element (DICOM Tag field (7FE0,0010)) of files with these types of compressed data. The Transfer Syntax UID is in the file's DICOM Tag field (0002,0010).

| UID Value | UID Name |
|---|---|
| 1.2.840.10008.1.2.4.50 | JPEG Baseline (Process 1): Default Transfer Syntax for Lossy JPEG 8 Bit Image Compression |
| 1.2.840.10008.1.2.4.51 | JPEG Extended (Process 2 & 4): Default Transfer Syntax for Lossy JPEG 12 Bit Image Compression (Process 4 only) |
| 1.2.840.10008.1.2.4.52 | JPEG Extended (Process 3 & 5) |
| 1.2.840.10008.1.2.4.53 | JPEG Spectral Selection, Non-Hierarchical (Process 6 & 8) |
| 1.2.840.10008.1.2.4.54 | JPEG Spectral Selection, Non-Hierarchical (Process 7 & 9) |
| 1.2.840.10008.1.2.4.55 | JPEG Full Progression, Non-Hierarchical (Process 10 & 12) |
| 1.2.840.10008.1.2.4.56 | JPEG Full Progression, Non-Hierarchical (Process 11 & 13) |
| 1.2.840.10008.1.2.4.57 | JPEG Lossless, Non-Hierarchical (Process 14) |
| 1.2.840.10008.1.2.4.58 | JPEG Lossless, Non-Hierarchical (Process 15) |
| 1.2.840.10008.1.2.4.59 | JPEG Extended, Hierarchical (Process 16 & 18) |
| 1.2.840.10008.1.2.4.60 | JPEG Extended, Hierarchical (Process 17 & 19) |
| 1.2.840.10008.1.2.4.61 | JPEG Spectral Selection, Hierarchical (Process 20 & 22) |
| 1.2.840.10008.1.2.4.62 | JPEG Spectral Selection, Hierarchical (Process 21 & 23) |
| 1.2.840.10008.1.2.4.63 | JPEG Full Progression, Hierarchical (Process 24 & 26) |
| 1.2.840.10008.1.2.4.64 | JPEG Full Progression, Hierarchical (Process 25 & 27) |
| 1.2.840.10008.1.2.4.65 | JPEG Lossless, Hierarchical (Process 28) |

*Table 0-2: Encapsulated Transfer Syntaxes NOT Supported*

| UID Value | UID Name |
|---|---|
| 1.2.840.10008.1.2.4.66 | JPEG Lossless, Hierarchical (Process 29) |
| 1.2.840.10008.1.2.4.70 | JPEG Lossless, Non-Hierarchical, First-Order Prediction (Process 14 [Selection Value 1]): Default Transfer Syntax for Lossless JPEG Image Compression |
| 1.2.840.10008.1.2.5 | RLE Lossless |

*Table 0-2: Encapsulated Transfer Syntaxes NOT Supported (Continued)*

## Encapsulated SOP Classes Supported

IDL supports reading DICOM Part 10 files whose contents encapsulate the data of the following SOP Classes. The SOP Class UID is in the file's DICOM Tag field (0008,0016).

| UID Value | UID Name |
|---|---|
| 1.2.840.10008.5.1.4.1.1.1 | CR Image Storage |
| 1.2.840.10008.5.1.4.1.1.2 | CT Image Storage |
| 1.2.840.10008.5.1.4.1.1.4 | MR Image Storage |
| 1.2.840.10008.5.1.4.1.1.6.1 | Ultrasound Image Storage |
| 1.2.840.10008.5.1.4.1.1.7 | Secondary Capture Image Storage |
| 1.2.840.10008.5.1.4.1.1.12.1 | X-Ray Angiographic Image Storage |
| 1.2.840.10008.5.1.4.1.1.12.2 | X-Ray Radiofluoroscopic Image Storage |
| 1.2.840.10008.5.1.4.1.1.20 | Nuclear Medicine Image Storage |
| 1.2.840.10008.5.1.4.1.1.128 | Positron Emission Tomography Image Storage |

*Table 0-3: Encapsulated SOP Classes Supported*

## Handling of odd length data elements

The DICOM Standard PS 3.5 (Data Structures and Encoding) specifies that the data element values which make up a DICOM data stream must be padded to an even length. The toolkit upon which IDL’s DICOM reading functionality is built strictly enforces this specification. If IDL encounters an incorrectly formed odd length data field while reading a DICOM Part 10 file it will report an error and stop the reading process.

## Handling of undefined VRs

The VR (Value Representation) of a data element describes the data type and format of that data element's values. If IDL encounters an undefined VR while reading a DICOM Part 10 file, it will set that data element's VR to be UN (unknown).

## Handling of retired and private data elements

Certain data elements are no longer supported under the v3.0 of the DICOM standard and are denoted as retired. Also, some DICOM implementations may require the communication of information that cannot be contained in standard data elements, and thus create private data elements to contain such information. Retired and private data elements should pose no problem to IDL’s DICOM Part 10 file reading capability. When IDL encounters a retired or private data element tag during reading a DICOM Part 10 file, it will treat it just like any standard data element: read the data value and allow it to be accessed via the IDLffDICOM::GetValue method.

# IDLffDICOM Properties

IDLffDICOM objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set via IDLffDICOM::Init.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## VERBOSE

A Boolean value that indicates whether informational messages are printed to the Output Log during the operational life of the object. If this value is true, the informational messages are printed to the Output Log. Otherwise, the messages are not printed.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLffDICOM::Cleanup

The IDLffDICOM::Cleanup procedure method destroys the IDLffDICOM object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLffDICOM::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER="*"))
obj->DumpElements
OBJ_DESTROY, obj

; Executing this statement should produce an invalid object
; reference error since obj no longer exists:
obj->DumpElements
```

## Version History

Introduced: 5.2

# IDLffDICOM::DumpElements

The IDLffDICOM::DumpElements procedure method dumps a description of the DICOM data elements of the IDLffDICOM object to the screen or to a file.

## Syntax

*Obj* -> [IDLffDICOM::]DumpElements [, *Filename*]

## Arguments

### Filename

A scalar string containing the full path and filename of the file to which to dump the elements. The file is written as ASCII text.

## Keywords

None

## Examples

The columns output by DumpElements are the element reference, the (group, element) tuple, the value representation, the description, the value length, and some of the data values.

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements

; Dump the contents of the current DICOM object to a file under
; Windows:
obj->DumpElements, 'c:\rsi\elements.dmp'

; Dump the contents of the current DICOM object to a file under
; UNIX:
obj->DumpElements, '/rsi/elements.dmp'

OBJ_DESTROY, obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::GetChildren

The IDLffDICOM::GetChildren function method is used to find the member element references of a DICOM sequence. It takes as an argument a scalar reference to a DICOM element representing the parent of the sequence.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]GetChildren(*Reference*)

## Return Value

Returns an array of references to the elements of the object that are members of that sequence. The scalar parent reference is possibly obtained by a previous call to GetReference or any method that generates a reference list. Any member of a sequence may also itself be the parent of another sequence. If the scalar reference argument is not the parent of a sequence, the method returns -1.

## Arguments

### Reference

A scalar reference to a DICOM element that is known to be the parent of a DICOM sequence.

## Keywords

None

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get a list of references to all elements that are sequences:
refs = obj->GetReference(VR='SQ')

; Cycle through the returned list and print out the immediate
; children references and descriptions of each sequence:
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   IF (refs[i] NE -1) THEN $
      BEGIN
         children = obj->GetChildren(refs[i])
```

```
            FOR j = 0, N_ELEMENTS(children)-1 DO $
               BEGIN
                  PRINT,children[j]
                    PRINT,obj->GetDescription(REFERENCE=children[j])
            ENDFOR
      ENDIF
   ENDFOR
   OBJ_DESTROY,obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::GetDescription

The IDLffDICOM::GetDescription function method takes optional DICOM group and element arguments and returns an array of STRING descriptions.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]GetDescription([*Group* [, *Element*]] [, REFERENCE=*list of element references*])

## Return Value

Returns an array of strings describing the field's contents as per the data dictionary in the DICOM specification PS 3.6. If no arguments or keywords are specified, the returned array contains the descriptions for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no DICOM elements can be found matching the search criteria, -1 will be returned.

## Arguments

### Group

An optional argument representing the value for the DICOM group to search for, i.e. '0018'x. If this argument is omitted, then all of the DICOM array elements are returned.

### Element

An optional argument specified only if the *Group* argument has also been specified. Set this argument to the value for the DICOM element for which to search, such as '0010'x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

## Keywords

### REFERENCE

Set this keyword to a list of element reference values from which to return description values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the description of the patient name element:
arr = obj->GetDescription('0010'x,'0010'x)
PRINT, arr

; Get array of all of the descriptions from the patient info group:
arr = obj->GetDescription('0010'x)
FOR i = 0, N_ELEMENTS(arr)-1 DO BEGIN
   PRINT, arr[i]
ENDFOR

OBJ_DESTROY, obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::GetElement

The IDLffDICOM::GetElement function method takes optional DICOM group and/or element arguments and returns an array of DICOM Element numbers for those parameters.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]GetElement([*Group* [, *Element*]] [, REFERENCE=*list of element references*])

## Return Value

Returns an array of integers representing the DICOM Element numbers for the parameters of the *Group* and *Element* arguments. If no arguments or keywords are specified, the returned array contains Element numbers for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

## Arguments

### Group

An optional argument representing the value for the DICOM group to search for, i.e. ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

### Element

An optional argument specified only if the Group argument has also been specified. Set this argument to the value for the DICOM element to search for, such as ‘0010’x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

## Keywords

### REFERENCE

Set this keyword to a list of element reference values from which to return element number values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')

; Get the element numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   num = obj->GetElement(REFERENCE=refs[i])
   PRINT,num
ENDFOR

; Get the element numbers from the Patient Info group, 0010:
elements = obj->GetElement('0010'x)
PRINT, elements

OBJ_DESTROY,obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::GetGroup

The IDLffDICOM::GetGroup function method takes optional DICOM group and/or element arguments and returns an array of DICOM Group numbers for those parameters.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]GetGroup([*Group*[, *Element*]]
[, REFERENCE=*list of element references*])

## Return Value

Returns an array of integers representing the DICOM Group numbers for *Group* parameters. If no arguments or keywords are specified, the returned array contains Group numbers for all groups in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

## Arguments

### Group

An optional argument representing the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

### Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as ‘0010’x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

## Keywords

### REFERENCE

Set this keyword to a list of element references from which to return group number values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get references to all elements with "patient" in the description:
refs = obj->GetReference(DESCRIPTION='patient')

; Get the group numbers of the elements containing "patient":
FOR i = 0, N_ELEMENTS(refs)-1 DO BEGIN
   num = obj->GetGroup(REFERENCE=refs[i])
   PRINT, num
ENDFOR

; Get the group numbers from the Patient Info group, 0010:
grp = obj->GetGroup('0010'x)
PRINT, grp

OBJ_DESTROY,obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::GetLength

The IDLffDICOM::GetLength function method takes optional DICOM group and/or element arguments and returns an array of LONGs.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]GetLength([*Group* [, *Element*]] [, REFERENCE=*list of element references*])

## Return Value

Returns an array of longword integers. The length is the field length that explicitly exists in the DICOM file, and represents the length of the element value in bytes. If no arguments or keywords are specified, the returned array contains the lengths for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

## Arguments

### Group

An optional argument representing the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, all DICOM array elements are returned.

### Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as ‘0010’x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

## Keywords

### REFERENCE

Set this keyword to a list of element references from which to return length values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the length of the patient name element:
arr = obj->GetLength('0010'x,'0010'x)
PRINT, arr

; Get an array of all of the lengths from the patient info group:
arr = obj->GetLength('0010'x)
PRINT, arr
OBJ_DESTROY, obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::GetParent

The IDLffDICOM::GetParent function method is used to find the parent references of a set of elements in a DICOM sequence.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]GetParent(*ReferenceList*)

## Return Value

Returns the parent references of a set of elements in a DICOM sequence. It takes as an argument an array of references that represent DICOM elements. If no members of the *ReferenceList* are members of a sequence, a -1 is returned, and for each member of the *ReferenceList* which is not a member of a sequence, a -1 is returned.

## Arguments

### ReferenceList

An array of references to DICOM elements that are known to be members of a DICOM sequence.

## Keywords

None

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj -> Read(DIALOG_PICKFILE(FILTER = '*'))

; Get the reference to the Referenced Study Sequence
; element, if it exists:
ref = obj -> GetReference('0008'x, '1110'x)
PRINT, ref
PRINT, obj -> GetDescription(REFERENCE = ref)

; Get and print the parent sequence, if it exists.
; This should result in a -1 since this element is not
; a member of a sequence:
parent = obj -> GetParent(ref)
PRINT, parent
```

```
PRINT, obj -> GetDescription(REFERENCE=parent)

; Get the children of the  Referenced Study Sequence
; element, if it exists:
refs = obj -> GetChildren(ref[0])
PRINT, refs
PRINT, obj -> GetDescription(REFERENCE = refs)
OBJ_DESTROY, obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::GetPreamble

The IDLffDICOM::GetPreamble function method returns the preamble of a DICOM v3.0 Part 10 file.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]GetPreamble()

## Return Value

Returns a 128-element byte array containing the preamble, which is a fixed 128 byte field available for implementation specified usage. If it is not used by the implementor of the file, it will be set to all zeroes.

## Arguments

None

## Keywords

None

## Examples

```
; Create a DICOM object, read a DICOM file:
obj = OBJ_NEW('IDLffDICOM')
var  = obj -> Read(DIALOG_PICKFILE(FILTER = '*'))

; Get an array of the byte contents of the DICOM file preamble:
arr = obj -> GetPreamble()
PRINT, arr

OBJ_DESTROY, obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::GetReference

The IDLffDICOM::GetReference function method takes optional DICOM group and/or element arguments and returns an array of references to matching elements in the object.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]GetReference([*Group* [, *Element*]] [, DESCRIPTION=*string*] [, VR=*DICOM VR string*])

## Return Value

Returns an array referencing the matching elements in the object. References are opaque, meaning that they have no specific significance other than a correspondence to the element they refer to. If no arguments or keywords are specified, the returned array contains references to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

## Arguments

### Group

An optional argument representing the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

### Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element to search for, such as ‘0010’x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

## Keywords

### DESCRIPTION

Set this keyword to a string containing text to be searched for in each element’s DICOM description. An element will be returned only if the text in this string can be found in the description. The text comparison is case-insensitive.

### VR

Set this keyword to a DICOM VR string. An element will be returned only if its value representation matches this string.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj -> Read(DIALOG_PICKFILE(FILTER = '*'))

; Get the reference to the patient name element:
ref = obj -> GetReference('0010'x,'0010'x)
PRINT, ref

; Get references to all elements with "patient" in the description:
refs = obj -> GetReference(DESCRIPTION = 'patient')
FOR i = 0, (N_ELEMENTS(refs) - 1) DO BEGIN
   PRINT, refs[i]
   PRINT, obj -> GetDescription(REFERENCE = refs[i])
ENDFOR

; Get references to all elements with a VR of DA (date):
refs = obj -> GetReference(vr = 'DA')
FOR i = 0, (N_ELEMENTS(refs) - 1) DO BEGIN
   PRINT, refs[i]
   PRINT, obj -> GetDescription(REFERENCE = refs[i])
ENDFOR

OBJ_DESTROY, obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::GetValue

This method takes optional DICOM group and/or element arguments and returns an array of POINTERs to the values of the elements matching those parameters.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]GetValue([*Group* [, *Element*]]
[, REFERENCE=*list of element references*] [, /NO_COPY])

## Return Value

Returns an array of pointers to the values of the elements matching the *Group* and *Element* parameters. If no arguments or keywords are specified, the returned array contains pointers to all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

## Arguments

### Group

Set this optional argument to the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

### Element

This optional argument can be specified only if the Group argument has also been specified. Set this to the value for the DICOM element for which to search, such as ‘0010’x. If this argument is omitted and the Group argument was specified, then all elements of the specified Group are returned.

## Keywords

### REFERENCE

Set this keyword to a list of element references from which to return pointer values.

### NO_COPY

If this keyword is set, the pointers returned point to the actual data in the object for the specified DICOM fields. If not set (the default), the pointers point to copies of the data instead, and need to be freed by using PTR_FREE.

## Examples

### Example 1

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the image data
array = obj->GetValue('7fe0'x, '0010'x)
OBJ_DESTROY, obj

TVScl, *array[0]
PTR_FREE, array
```

### Example 2

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get all of the image data element(s), 7fe0,0010, from the file:
array = obj->GetValue('7fe0'x,'0010'x,/NO_COPY)

; Get the row & column size of the image(s):
rows = obj->GetValue('0028'x,'0010'x,/NO_COPY)
cols = obj->GetValue('0028'x,'0011'x,/NO_COPY)

; If the image has a samples per pixel value greater than 1
; it is most likely a color image, get the samples per pixel:
isColor = 0
samples = obj->GetValue('0028'x,'0002'x,/NO_COPY)
IF (SIZE(samples,/N_DIMENSIONS) NE 0) THEN BEGIN
   IF (*samples[0] GT 1) THEN isColor = 1
ENDIF

; Next, we need to differentiate between files with color data
; that is either color-by-plane or color-by-pixel, get the planar
; configuration:
IF (isColor EQ 1) THEN BEGIN
   isPlanar = 0
   planar = obj->GetValue('0028'x,'0006'x, /NO_COPY)
   IF (SIZE(planar, /N_DIMENSIONS) NE 0) THEN BEGIN
```

```
      IF (*planar[0] EQ 1) THEN isPlanar = 1
   ENDIF
ENDIF

; Display the first NumWin images from the file:
IF N_ELEMENTS(array) GT 10 THEN NumWin = 10 $
ELSE NumWin = N_ELEMENTS(array)
offset = 0
FOR index = 0, NumWin-1 DO BEGIN
   ; Create window for each image that is the size of the image:
   WINDOW,index,XSize=*cols[0],YSize=*rows[0],XPos=offset,YPos=0
   WSET,index
   ; Display the image data
   IF (isColor EQ 1) THEN $
       IF (isPlanar EQ 1) THEN $

# IDLffDICOM::GetVR

The IDLffDICOM::GetVR function method takes optional DICOM group and/or element arguments and returns an array of VR (Value Representation) STRINGs for those parameters.

## Syntax

*array* = *Obj* -> [IDLffDICOM::]GetVR([*Group* [, *Element*]]
[, REFERENCE=*list of references*])

## Return Value

Returns an array of strings containing VRs (Value Representations) for the *Group* and *Element* parameters. A VR is a DICOM value representation as described in the DICOM specification PS 3.5. If no arguments or keywords are specified, the returned array contains VRs for all elements in the object. The effect of multiple keywords and parameters is to AND their results. If no matching elements can be found, the function returns -1.

## Arguments

### Group

An optional argument representing the value for the DICOM group for which to search, such as ‘0018’x. If this argument is omitted, then all of the DICOM array elements are returned.

### Element

An optional argument specified only if the *Group* argument has also been specified. Set this to the value for the DICOM element for which to search, such as ‘0010’x. If this argument is omitted and the *Group* argument was specified, then all elements of the specified *Group* are returned.

## Keywords

### REFERENCE

Use the specified list of references from which to return VR STRING values.

## Examples

```
obj = OBJ_NEW('IDLffDICOM')
read = obj->Read(DIALOG_PICKFILE(FILTER='*'))

; Get the VR of the patient name element:
arr = obj->GetVR('0010'x,'0010'x)
PRINT, arr

; Get an array of all of the VRs from the patient info group:
arr = obj->GetVR('0010'x)
PRINT, arr

OBJ_DESTROY,obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::Init

The IDLffDICOM::Init function method creates a new IDLffDICOM object and optionally reads the specified file as defined in the IDLffDICOM::Read method.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Result* = OBJ_NEW( 'IDLffDICOM' [, *Filename*] [, *PROPERTY=value*])

or

*Result = Obj* -> [IDLffDICOM::]Init([*Filename*] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Filename

An optional scalar string argument containing the full path and filename of a DICOM v3.0 Part 10 file to open, read into memory, then close, when the object is created. It is the same as calling: result -> Read(Filename).

## Keywords

Any property listed under “IDLffDICOM Properties” on page 2568 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Examples

```
; Create a DICOM object:
obj = OBJ_NEW( 'IDLffDICOM' )

; Create a DICOM object and read in a DICOM file named ct_head.dcm
; under Microsoft Windows:
obj = OBJ_NEW( 'IDLffDICOM', $
   'c:\rsi\idl52\examples\data\mr_brain.dcm' )

; Create a DICOM object and allow the user to choose a DICOM file
; to be read:
obj = OBJ_NEW( 'IDLffDICOM', DIALOG_PICKFILE(FILTER='*'))
```

## Version History

Introduced: 5.2

# IDLffDICOM::Read

The IDLffDICOM::Read function method opens and reads from the specified disk file, places the information into the DICOM object, then closes the file.

## Syntax

*Result* = *Obj* -> [IDLffDICOM::]Read(*Filename* [, ENDIAN={1 | 2 | 3 | 4}])

## Return Value

Return a 1 if successful and 0 otherwise.

## Arguments

### Filename

A scalar string argument containing the full path and filename of a DICOM Part 10 file to open and read into memory.

## Keywords

### ENDIAN

Set this keyword to configure the endian format when reading a DICOM file.

- 1 = Implicit VR Little Endian
- 2 = Explicit VR Little Endian
- 3 = Implicit VR Big Endian
- 4 = Explicit VR Big Endian

## Examples

```
; Create a DICOM object and read a DICOM file:
obj = OBJ_NEW('IDLffDICOM')
var  = obj -> Read(DIALOG_PICKFILE(FILTER = '*'))
OBJ_DESTROY, obj
```

## Version History

Introduced: 5.2

# IDLffDICOM::Reset

The IDLffDICOM::Reset procedure method removes all of the elements from the IDLffDICOM object, leaving the object otherwise intact.

## Syntax

*Obj* -> [IDLffDICOM::]Reset

## Arguments

None

## Keywords

None

## Examples

```
; Create a DICOM object, read a DICOM file and dump its contents:
obj = OBJ_NEW( 'IDLffDICOM' )
var  = obj->Read(DIALOG_PICKFILE(FILTER='*'))
obj->DumpElements
obj->Reset

; DumpElements should produce no output here:
obj->DumpElements
OBJ_DESTROY, obj
```

## Version History

Introduced: 5.2

# IDLffDXF

An IDLffDXF object contains geometry, connectivity and attributes for graphics primitives.

**Note**

IDL supports version 2.003 of the DXF Library.

This object treats a DXF file as a list of entities. Note, these are not directly mapped to DXF entity types, rather they are an abstraction of the DXF types. The Read method is used to read the contents of a DXF file into the current entity list. The user may then query this list using the GetContents method to determine the types and number of entities in the file. The user may retrieve arrays of entities from the list using the GetEntity method and add additional entities using the PutEntity method. Entities can also be removed from the list (RemoveEntity) or the entire list destroyed (Reset). The current list of entities can also be written to disk as a DXF file. Note, this object converts DXF entities to IDL entities and back. This conversion is not reversible; thus, if a DXF file is read and then written, the data in the file is not changed, but the internal DXF entity types may be changed by IDL. As an example, DXF face3d entities may be written as DXF polyline entities.

The object has one attribute which can be modified using the Get/SetPalette methods. This palette is used to convert color index values. The palette is not actually written to the DXF file. So, if the user wanted to specify entity colors from a 256 entry table, that table would be set using SetPalette, but the actual colors written to the file are the closest colors matched to the fixed AutoCAD color palette. There are two special color values: (0) = color by block color, (256) = color by layer color.

In this object, blocks and layers are treated as named entities with attributes, but are special in that all other entities have a block and layer entity reference in them. This allows the user to use these entity names as filters for many operations. There is a default block and a default layer. The default block has the name “” (the null string), and the default layer is '0'. The user may change the (non-name) attributes for these implicit blocks using PutEntity.

## Superclasses

This class has no superclass.

## Creation

See “IDLffDXF::Init” on page 2616

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- IDLffDXF::Cleanup
- IDLffDXF::GetContents
- IDLffDXF::GetEntity
- IDLffDXF::GetPalette
- IDLffDXF::Init
- IDLffDXF::PutEntity
- IDLffDXF::Read
- IDLffDXF::RemoveEntity
- IDLffDXF::Reset
- IDLffDXF::SetPalette
- IDLffDXF::Write

## Version History

Introduced: 5.2

# IDLffDXF Properties

Objects of this class have no properties of their own.

# IDLffDXF::Cleanup

The IDLffDXF::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLffDXF::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.2

# IDLffDXF::GetContents

The IDLffDXF::GetContents function method returns a description of the content of the DXF file.

See the Examples following the GetEntity method description for an illustration of the difference between the GetContents and the GetEntity methods.

The Read or PutEntity methods must have been called previously for the results of this method to be valid.

| Valid DXF ENTITY Types | DXF_TYPE ( 0=default) |
|---|---|
| ARC | 1 |
| CIRCLE | 2 |
| ELLIPSE | 3 |
| LINE | 4 |
| LINE3D | 5 |
| TRACE | 6 |
| POLYLINE | 7 |
| LWPOLYLINE | 8 |
| POLYGON | 9 |
| FACE3D | 10 |
| SOLID | 11 |
| RAY | 12 |
| XLINE | 13 |
| TEXT | 14 |
| MTEXT | 15 |
| POINT | 16 |
| SPLINE | 17 |

*Table 0-4: DXF Entity Types*

| Valid DXF ENTITY Types | DXF_TYPE ( 0=default) |
|---|---|
| BLOCK | 18 |
| INSERT | 19 |
| LAYER | 20 |

*Table 0-4: DXF Entity Types (Continued)*

This object uses a small number of IDL named structures to return the data associated which each entity. This means that several of these DXF types are returned in the same structures, using different values of the DXF_TYPE field. The mapping of DXF entities to IDL named structures is as follows (each of these structures is documented in the GetEntity method):

| IDL Structure | DXF Entity |
|---|---|
| IDL_DXF_ELLIPSE | arc, circle, ellipse |
| IDL_DXF_POLYLINE | line, line3d, trace, polyline, lwpolyline |
| IDL_DXF_POLYGON | face3d, solid, polyline (3-d mesh) |
| IDL_DXF_POINT | point |
| IDL_DXF_XLINE | ray, xline |
| IDL_DXF_SPLINE | spline |
| IDL_DXF_TEXT | text, multitext |
| IDL_DXF_BLOCK | block |
| IDL_DXF_INSERT | insert |
| IDL_DXF_LAYER | layer |

*Table 0-5: DXF mapping to IDL structures*

# Syntax

*Result* = *Obj*-> [IDLffDXF::]GetContents( [*Filter*] [BLOCK=*string*] [, COUNT=*variable*] [LAYER=*string*] )

# Return Value

Returns an integer array containing the DXF entity type codes and the number of occurrences of each entity type contained in the object

# Arguments

## Filter

An integer array of the DXF entity types to which the return types are restricted. If set, Result can contain only types given in this argument and count will also reflect that restriction.

# Keywords

## BLOCK

Set this keyword to a string value containing the block name to obtain the entities from. The default is all blocks.

## COUNT

A long array containing the number of each entity type contained within the DXF object. If the Filter argument was provided, the numbers reflect the reduced set of entities caused by the Filter argument.

## LAYER

Set this keyword to a string value containing the layer name to obtain the entities from. The default is all layers.

# Version History

Introduced: 5.2

# IDLffDXF::GetEntity

The IDLffDXF::GetEntity function method returns an array of data for the requested entity type.

## Syntax

*Result* = *Obj*-> [IDLffDXF::]GetEntity(*Type* [, BLOCK=*string*] [, INDEX=*value*] [, LAYER=*string*])

## Return Value

Returns one of the named structure formats described in “Structure Formats” on page 2604.

## Arguments

### Type

The integer DXF entity type from which to obtain the geometry information.

## Keywords

### BLOCK

Set this keyword to a block name specifying the graphic block from which to obtain the entity geometry information. The default is all blocks. Setting this keyword to the null string " " will cause this method to only return entities from the default DXF entity block.

### INDEX

Set this keyword to a scalar index or a long array of indices of entities of the given type to return. If not set, this method returns all entities for the given type.

### LAYER

Set this keyword to a string value containing the layer name to obtain the entities from. The default is all layers.

# Fields Common to All Structures

## BLOCK

The name of the block this entity is in (these may be in the default block “”).

## COLOR

A color index value into the current object palette with 0=use block color and 256=use layer color.

## EXTRUSION

The DXF extrusion vector (if any).

## LAYER

The name of the layer this entity is in (the default layer is '0').

## LINESTYLE

Defined the same as the user linestyle for IDLgrPolyline::Init.

**Note**

IDL will always return a solid line regardless of the linestyle in DXF

## THICKNESS

In AutoCAD units.

## DXF_TYPE

Set to one of the values listed in IDLffDXF::GetContents.

**Note**

It is the user’s responsibility to free all the pointers returned in these structures when the entity is no longer needed.

# Structure Formats

## Structure IDL_DXF_ELLIPSE

| Field | Data Type |
|---|---|
| PT0 | Double [3] |
| PT1_OFFSET | Double [3] |
| MIN_TO_MAJ_RATIO | Double |
| START_ANGLE | Double |
| END_ANGLE | Double |
| EXTRUSION | Double [3] |
| LINESTYLE | Integer [2] |
| THICKNESS | Double |
| COLOR | Integer |
| DXF_TYPE | Integer |
| BLOCK | String |
| LAYER | String |

*Table 0-6: Fields of the IDL_DXF_ELLIPSE Structure*

This object is centered at PT0 and has a radius defined by the vector PT1_OFFSET. This vector determines the length and orientation of the major axis of an ellipse as well.

The MIN_TO_MAJ_RATIO value specifies the length of the minor axis as a fraction of the major axis length. For a circle, this value is 1.0.

The START_ANGLE and END_ANGLE values select the portion of the curve to be drawn. If they are equal, the entire circle or ellipse is drawn.

## Structure IDL_DXF_POLYGON

| Field | Data Type |
|---|---|
| VERTICES | Pointer (to an array of 3-D points) |
| CONNECTIVITY | Pointer (to an array of integers) |
| VERTEX_COLORS | Pointer (to an array of integers) |
| MESH_DIMS | Integer [2] |
| CLOSED | Integer [2] |
| COLOR | Integer |
| EXTRUSION | Double [3] |
| FIT_TYPE | Integer |
| CURVE_FIT | Integer |
| SPLINE_FIT | Integer |
| DXF_TYPE | Integer |
| BLOCK | String |
| LAYER | String |

*Table 0-7: Fields of the IDL_DXF_POLYGON Structure*

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polygons (see the POLYGONS keyword for IDLgrPolygon::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polygon assumes.

## Structure IDL_DXF_POLYLINE

| Field | Data Type |
|---|---|
| VERTICES | Pointer (to an array of 3-D points) |
| CONNECTIVITY | Pointer (to an array of integers) |
| VERTEX_COLORS | Pointer (to an array of integers) |
| COLOR | Integer |
| MESH_DIMS | Integer [2] |
| CLOSED | Integer [2] |
| THICKNESS | Double |
| LINESTYLE | Integer [2] |
| EXTRUSION | Double [3] |
| FIT_TYPE | String |
| CURVE_FIT | Integer |
| SPLINE_FIT | Integer |
| DXF_TYPE | Integer |
| BLOCK | String |
| LAYER | String |

*Table 0-8: Fields of the IDL_DXF_POLYLINE Structure*

VERTICES is a pointer to an array of dimension [3, n] containing the points for this entity.

CONNECTIVITY is the array used to connect these points into polylines (see the POLYLINES keyword for IDLgrPolyline::Init). If this array is not present, the connectivity is implicit in (U, V) space defined by the values in MESH_DIMS; the vertices represent a quad mesh of dimensions (MESH_DIMS[0], MESH_DIMS[1]).

VERTEX_COLORS points to an array of color index values for each of the vertices. If a quad mesh is being returned, it can be closed in either dimension according to the CLOSED array.

FIT_TYPE, CURVE_FIT, and SPLINE_FIT return the type of curve fit (if any) this polyline assumes.

## Structure IDL_DXF_POINT

| Field | Data Type |
|---|---|
| PT0 | Double [3] |
| UCSX_ANGLE | Double |
| THICKNESS | Double |
| COLOR | Integer |
| DXF_TYPE | Integer |
| BLOCK | String |
| LAYER | String |

*Table 0-9: Fields of the IDL_DXF_POINT Structure*

PT0 is the location of the point in space.

UCSX_ANGLE is an internal DXF orientation parameter used for symbol plotting.

## Structure IDL_DXF_SPLINE

| Field | Data Type |
|---|---|
| CTR_PTS | Pointer |
| FIT_PTS | Pointer |
| KNOTS | Pointer |
| WEIGHTS | Pointer |
| COLOR | Integer |
| DEGREE | Integer |
| PERIODIC | Integer |
| RATIONAL | Integer |
| PLANAR | Integer |
| LINEAR | Integer |
| KNOT_TOLERANCE | Double |
| CTL_TOLERANCE | Double |
| FIT_TOLERANCE | Double |
| START_TANGENT | Double [3] |
| END_TANGENT | Double [3] |
| THICKNESS | Double |
| LINESTYLE | Integer [2] |
| EXTRUSION | Double [3] |
| DXF_TYPE | Integer |
| BLOCK | String |
| LAYER | String |

*Table 0-10: Fields of the IDL_DXF_SPLINE Structure*

This structure is returned verbatim from the DXF spline structure without interpretation. It is up to the user to interpret these values.

## Structure IDL_DXF_TXT

| Field | Data Type |
|---|---|
| PT0 | Double [3] |
| TEXT_STR | String |
| COLOR | Integer |
| HEIGHT | Double |
| WIDTH_FACTOR | Double |
| BOX_WIDTH | Double |
| DIRECTION | Double [3] |
| ROT_ANGLE | Double |
| JUSTIFICATION | Integer (0=left, 1=center, 2=right, 3=aligned, 4=middle, 5=fit) |
| VERTICAL_ALIGN | Integer (0=baseline, 1=bottom, 2=middle, 3=top) |
| SHAPE_FILE | String |
| THICKNESS | Double |
| EXTRUSION | Double [3] |
| DXF_TYPE | Integer |
| BLOCK | String |
| LAYER | String |

*Table 0-11: Fields of the IDL_DXF_TXT Structure*

PT0 is the location of the text string.

TEXT_STR is the actual string.

HEIGHT specifies the overall scaling of the glyphs while WIDTH_FACTOR is a correction in the baseline direction (anisotropic scaling). For multi-line text, BOX_WIDTH determines where the line breaks should be placed (0.0 for single line text).

The text baseline is specified by DIRECTION and its rotation about the *z*-axis is specified by ROT_ANGLE. Justification is specified by JUSTIFICATION and VERTICAL_ALIGN. SHAPE_FILE is the name of the glyph file used to image this string. The shape file is NOT read by IDL.

## Structure IDL_DXF_XLINE

| Field | Data Type |
|---|---|
| PT0 | Double [3] |
| UNIT_VEC | Double [3] |
| COLOR | Integer |
| THICKNESS | Double |
| LINESTYLE | Integer [2] |
| EXTRUSION | Double [3] |
| DXF_TYPE | Integer |
| BLOCK | String |
| LAYER | String |

*Table 0-12: Fields of the IDL_DXF_XLINE Structure*

PT0 is the start of a ray or a point on a infinite line in space in the case of an XLINE entity.

UNIT_VEC determines the direction of the line in space.

## Structure IDL_DXF_INSERT

| Field | Data Type |
|---|---|
| SCALE | Double [3] |
| PT0 | Double [3] |
| ROTATION | Double |
| INSTANCE_BLOCK | String |
| NUM_ROW_COL | Integer [2] |
| DISTANCE_BETWEEN | Double [2] |
| DXF_TYPE | Integer |
| BLOCK | String |
| COLOR | Integer |
| LAYER | String |

*Table 0-13: Fields of the IDL_DXF_INSERT Structure*

The insert entity allows for the “instancing” of a block in a grid fashion.

INSTANCE_BLOCK is the name of a block to repeat.

The block is scaled by SCALE and rotated about the Z axis by ROTATION. The grid begins at PT0 and contains the number of rows and columns specified by NUM_ROW_COL (Note: 0 rows or columns will always give a single instance of the block).

The spacing of the grid is specified by DISTANCE_BETWEEN.

### Structure IDL_DXF_BLOCK

| Field | Data Type |
|---|---|
| PT0 | Double [3] |
| COLOR | Integer |
| NAME | String |
| DXF_TYPE | Integer |

*Table 0-14: Fields of the IDL_DXF_BLOCK Structure*

This entity specifies a BLOCK. Blocks have a location in space (PT0) [objects in the block are interpreted relative to this point], a name, and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

### Structure IDL_DXF_LAYER

| Field | Data Type |
|---|---|
| COLOR | Integer |
| NAME | String |
| DXF_TYPE | Integer |

*Table 0-15: Fields of the IDL_DXF_LAYER Structure*

This entity specifies a LAYER. Layer is a NAME and a COLOR. They are not contained in layers or other blocks, so these fields are not present.

## Examples

This example illustrates the difference between the GetEntity and GetContents methods within the IDLffDXF object method. The GetContents method gives a description of the content of the file read, listing the entity types and the number of occurrences. GetEntity accesses the values returned by GetContents and determines how the entities can be logically combined into common structures for drawing efficiency.

```
PRO view_heart
; Determine path to data file.
heartFile = FILEPATH('heart.dxf', $
   SUBDIRECTORY = ['examples', 'data'])
; Initialize DXF data access object.
oHeart = OBJ_NEW('IDLffDXF')
; Read data within DXF file into access object.
status = oHeart -> Read(heartFile)
; Determine what type of entities (and how many of
; each entity) exist in the file.
heartTypes = oHeart -> GetContents(COUNT = heartCounts)
PRINT, 'Entity Types:   ', heartTypes
PRINT, 'Count of Types: ', heartCounts
; Initialize a model for displaying polygon and polyline
; objects.
oModel = OBJ_NEW('IDLgrModel')
; Obtain the tissue data.  The tissue is accessed into
; IDL as a single polygon.
tissue = oHeart -> GetEntity(heartTypes[1])
HELP, tissue
HELP, tissue, /STRUCTURE
; Initialize color parameter.
tissueColor = [255, 0, 0]
; Initialize polygon data.
vertices = tissue.vertices
connectivity = tissue.connectivity
; Initialize the polygon object.
oTissue = OBJ_NEW('IDLgrPolygon', $
   *vertices, POLYGONS = *connectivity, $
   COLOR = tissueColor)
; Add the polygon to the model.
oModel -> Add, oTissue
; Clean-up all the related pointers.
PTR_FREE, tissue.vertices, tissue.connectivity, $
   tissue.vertex_colors
PTR_FREE, vertices, connectivity
; Display the polylines and the polygon in the XOBJVIEW
; utility.
XOBJVIEW, oModel, /BLOCK, SCALE = 0.75
; Clean-up the object references.
OBJ_DESTROY, [oHeart, oModel]
END
```

An XOBJVIEW window with the mesh heart object appears when this program is compiled and run. The following lines are found in the IDLDE Output Log window.

```
IDL> view_heart
% Compiled module: VIEW_HEART.
% Compiled module: FILEPATH.
```

```
% Loaded DLM: DXF.
Entity Types:              7          10          18          20
Count of Types:           13        1624           1           2
```

The Entity Types (7, 10, 18, and 20) are the GetContents method return values corresponding to the occurrence of DXF ENTITY types found in the object: POLYLINES, FACE3D, BLOCK, and LAYER, respectively. Note there are a total of 1624 FACE3D entity types, but for efficiency and speed IDL logically combines all of the similar entities into a single structure that can be used in an IDLgrPolygon object. This is illustrated by the output resulting from the first Help command in the program as shown below.

```
TISSUE          STRUCT    = -> IDL_DXF_POLYGON Array[1]
** Structure IDL_DXF_POLYGON, 13 tags, length=72:
   EXTRUSION       DOUBLE    Array[3]

   CONNECTIVITY    POINTER   <PtrHeapVar4>
   VERTEX_COLORS   POINTER   <PtrHeapVar5>
   MESH_DIMS       INT       Array[2]
   CLOSED          INT       Array[2]
   COLOR           INT            256
   FIT_TYPE        INT             -1
   CURVE_FIT       INT              0
   SPLINE_FIT      INT              0
   DXF_TYPE        INT             10
   BLOCK           STRING    ''
   LAYER           STRING    '0----'
% Compiled module: XOBJVIEW.
% Compiled module: UNIQ.
% Compiled module: IDENTITY.
% Compiled module: XMANAGER.
```

Note that the tissue is represented as an array of polygons having 1 element. This is evident by the mesh representation of the heart object showing the 1624 individual polygons as a single object.

## Version History

Introduced: 5.2

# IDLffDXF::GetPalette

The IDLffDXF::GetPalette procedure method returns the current color table in the object.

## Syntax

*Obj*->[IDLffDXF::]GetPalette, *Red*, *Green*, *Blue*

## Arguments

### Red

Returns an array of the red components to the current color table.

### Green

Returns an array of the green components to the current color table.

### Blue

Returns an array of the blue components to the current color table.

## Keywords

None

## Version History

Introduced: 5.2

# IDLffDXF::Init

The IDLffDXF::Init function method initializes the DXF object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Result* = OBJ_NEW('IDLffDXF' [, *Filename*] )

or

*Result* = *Obj* -> [IDLffDXF::]Init( [*Filename*] ) (*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Filename

A scalar string optional argument containing the full path and filename of a DXF file to be read as the object is created.

## Keywords

None

## Version History

Introduced: 5.2

# IDLffDXF::PutEntity

The IDLffDXF::PutEntity procedure method inserts an entity into the DXF object. The type of the entity is determined from the DXF_TYPE field of the entity structure. If DXF_TYPE is set to 0, the type is implied by the entity structure.

**Note**

Line3D entity types will be written as Line entities due to the obsolete status of Line3D. Polyline entities will be automatically converted to Lightweight Polylines where applicable.

## Syntax

*Obj* -> [IDLffDXF::]PutEntity, *Data*

## Arguments

### Data

An array of Entity structures as defined by the GetEntity method.

**Note**

If the entity references a non-existent block or layer, one will automatically be created. Blocks and layers can also be created by passing IDL_DXF_BLOCK or IDL_DXF_LAYER structures to this routine.

## Keywords

None

## Version History

Introduced: 5.2

# IDLffDXF::Read

The IDLffDXF::Read function method reads a file, parsing the DXF object information contained in the file, and inserts it into itself.

## Syntax

*Result* = *Obj*`->` [IDLffDXF::]Read(*Filename*)

## Return Value

Returns a 1 indicating success in reading the file, otherwise 0.

## Arguments

### Filename

A scalar string containing the full path and filename of the DXF file to be read.

## Keywords

None

## Examples

```
; Read all the lines from the electrical layer:
oDXF = OBJ_NEW('IDLffDXF')
IF (oDXF->Read('myDXF.dxf')) THEN BEGIN
   contents = oDXF->GetContents(4,COUNT=numLines, $
      LAYER='Electrical')
   IF (numLines ne 0) THEN BEGIN
      lines = oDXF->GetEntity(4,LAYER='Electrical')
   ENDIF
ENDIF
```

## Version History

Introduced: 5.2

# IDLffDXF::RemoveEntity

The IDLffDXF::RemoveEntity procedure method removes the specified entity or entities from the DXF object.

## Syntax

*Obj* -> [IDLffDXF::]RemoveEntity[, *Type*] [, INDEX=*value*]

## Arguments

### Type

An optional scalar string containing the DXF type to be removed from the DXF object.

**Note**

Specifying a block or layer entity will cause all the entities in that layer or block to be removed.

## Keywords

### INDEX

Set this keyword to a scalar long or a long array of indices to remove from the DXF object. If not set, or set negative, all entities of the given type are removed.

## Version History

Introduced: 5.2

# IDLffDXF::Reset

The IDLffDXF::Reset procedure method removes all the entities from the DXF object.

## Syntax

*Obj*->[IDLffDXF::]Reset

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.2

# IDLffDXF::SetPalette

The IDLffDXF::SetPalette procedure method sets the current color table in the object.

## Syntax

*Obj*->[IDLffDXF::]SetPalette, *Red*, *Green*, *Blue*

## Arguments

### Red

Sets the red components of the current color table to this array.

### Green

Sets the green components of the current color table to this array.

### Blue

Sets the blue components of the current color table to this array.

## Keywords

None

## Version History

Introduced: 5.2

# IDLffDXF::Write

The IDLffDXF::Write function method writes a file for the DXF entity information this object contains.

## Syntax

*Result* = *Obj*`->` [IDLffDXF::]Write(*Filename*)

## Return Value

Returns a 1 if successful in writing the file, 0 otherwise.

## Arguments

### Filename

A scalar string containing the full path and filename of the DXF file to be written.

## Keywords

None

## Examples

```
; Write a square to a new DXF file using lines:
oDXF = OBJ_NEW('IDLffDXF')
lines = {IDL_DXF_POLYLINE}
lines.dxf_type = 4
lines.layer='myLayer'
lines.thickness = 1.0

; Create clockwise square:
lines = REPLICATE(lines, 4)
lines[0].vertices = PTR_NEW([[0.0,0.0,0.0], $
     [0.0,1.0,0.0]])
lines[0].connectivity = PTR_NEW([0,1])
lines[1].vertices = PTR_NEW([[0.0,1.0,0.0], $
    [1.0,1.0,0.0]])
lines[1].connectivity = PTR_NEW([0,1])
lines[2].vertices = PTR_NEW([[1.0,1.0,0.0], $
    [1.0,0.0,0.0]])
lines[2].connectivity = PTR_NEW([0,1])
lines[3].vertices = PTR_NEW([[1.0,0.0,0.0], $
```

```
    [0.0,0.0,0.0]])
lines[3].connectivity = PTR_NEW([0,1])
oDXF->PutEntity, lines
IF (not oDXF->Write('mySquare.dxf')) THEN $
   PRINT, 'Write Failed.'
   ; Clean up the memory in the structs:
   OBJ_DESTROY, oDXF
   FOR i=0,3 DO BEGIN
      PTR_FREE, lines[i].vertices, lines[i].connectivity
ENDFOR
```

## Version History

Introduced: 5.2

# IDLffLanguageCat

The IDLffLanguageCat object provides an interface to IDL language catalog files.

**Note**

This object is not savable. Restored IDLffLanguageCat objects may contain invalid data.

**Note**

This object is not intended to be created with OBJ_NEW. The MSG_CAT_OPEN function is used to return the correct object reference.

## Superclasses

This class has no superclasses.

## Creation

See MSG_CAT_OPEN.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- IDLffLanguageCat::IsValid
- IDLffLanguageCat::Query
- IDLffLanguageCat::SetCatalog

## Version History

Introduced: 5.2.1

## See Also

MSG_CAT_CLOSE, MSG_CAT_COMPILE, MSG_CAT_OPEN

# IDLffLanguageCat Properties

Objects of this class have no properties of their own.

# IDLffLanguageCat::IsValid

The IDLffLanguageCat::IsValid function method is used to determine whether the object has a valid catalog.

## Syntax

*Result* = *Obj* ->[IDLffLanguageCat::]IsValid()

## Return Value

Returns a 1 if the file is valid, 0 otherwise.

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.2.1

# IDLffLanguageCat::Query

The IDLffLanguageCat::Query function method is used to return the language string associated with the given key.

## Syntax

*Result* = *Obj* ->[IDLffLanguageCat::]Query(*Key* [, DEFAULT_STRING=*string*])

## Return Value

Returns a string representing the language associated with the given key. If the key is not found in the given catalog, the default string is returned.

## Arguments

### Key

The scalar or array of (string) keys associated with the desired language string. If key is an array, *Result* will be a string array of the associated language strings.

## Keywords

### DEFAULT_STRING

Set this keyword to the desired value of the return string if the key cannot be found in the catalog file. The default value is the empty string.

## Version History

Introduced: 5.2.1

# IDLffLanguageCat::SetCatalog

The IDLffLanguageCat::SetCatalog function method is used to set the appropriate catalog file.

## Syntax

*Result* = *Obj* ->[IDLffLanguageCat::]SetCatalog(*Application* [, FILENAME=*string*] [, LOCALE=*string*] [, PATH=*string*])

## Return Value

Returns 1 upon success, and 0 on failure

## Arguments

### Application

A scalar string representing the name of the desired application's catalog file.

## Keywords

### FILENAME

Set this keyword to a scalar string containing the full path and filename of the catalog file to open. If this keyword is set, *application*, PATH, and LOCALE are ignored.

### LOCALE

Set this keyword to the desired locale for the catalog file. If not set, the current locale is used.

### PATH

Set this keyword to a scalar string containing the path to search for language catalog files. The default is the current directory.

## Version History

Introduced: 5.2.1

# IDLffMrSID

An IDLffMrSID object class is used to query information about and load image data from a MrSID (`.sid`) image file.

## Superclasses

This class has no superclasses.

## Creation

See IDLffMrSID::Init

## Properties

Objects of this class have the following properties. See “IDLffMrSID Properties” on page 2630 for details on individual properties.

- QUIET

## Methods

This class has the following methods:

- IDLffMrSID::Cleanup
- IDLffMrSID::GetDimsAtLevel
- IDLffMrSID::GetImageData
- IDLffMrSID::GetProperty
- IDLffMrSID::Init

## Version History

Introduced: 5.5

# IDLffMrSID Properties

IDLffMrSID objects have the following properties. Properties with the word “Yes” in the “Init” column of the property table can be set via IDLffMrSID::Init.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## QUIET

A Boolean value to indicate whether error messages are suppressed while constructing the IDLffMrSID object. If this value is true, the errors messages are suppressed. Otherwise, the messages are printed to the Output Log.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLffMrSID::Cleanup

The IDLffMrSID::Cleanup procedure method deletes all MrSID objects, closing the MrSID file in the process. It also deletes the IDL objects used to communicate with the MrSID library.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLffMrSID::]Cleanup (*Only in subclass' Cleanup metho*d.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.5

# IDLffMrSID::GetDimsAtLevel

The IDLffMrSID::GetDimsAtLevel function method is used to retrieve the dimensions of the image at a given level. This can be used, for example, to determine what level is required to fit the image into a certain area.

## Syntax

*Result* = *Obj* -> [IDLffMrSID::]GetDimsAtLevel (*Level*)

## Return Value

Returns a floating-point two-element vector containing the dimensions of the image at a given level.

## Arguments

### Level

A scalar integer specifying the level at which the dimensions are to be determined. This level must be in the range returned by the LEVELS keyword of IDLffMrSID::GetProperty.

## Keywords

None

## Examples

Initialize the MrSID file object.

```
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))
```

Get the range of levels of resolution contained within the file.

```
oFile -> GetProperty, LEVELS = lvls
PRINT, lvls
```

IDL prints,

```
-9   4
```

Print the image dimensions at the lowest image resolution where image level = 4.

```
imgLevelA = MAX(lvls)
dimsAtA = oFile -> GetDimsAtLevel(imgLevelA)
PRINT, 'Dimensions of lowest resolution image is', dimsAtA
```

IDL prints,

```
32   32
```

Print the image dimensions at full resolution where image level = 0

```
dimsAtFull = oFile -> GetDimsAtLevel(0)
PRINT, 'Dimensions of full resolution image is', dimsAtFull
```

IDL prints,

```
512   512
```

Print the image dimensions at the highest resolution where image level = -9

```
highestLvl = MIN(lvls)
dimsAtHighest = oFile -> GetDimsAtLevel(highestLvl)
PRINT, 'Dimensions of highest resolution image is', dimsAtHighest
```

IDL prints,

```
262144   262144
```

Clean up object references.

```
OBJ_DESTROY, [oFile]
```

## Version History

Introduced: 5.5

# IDLffMrSID::GetImageData

The IDLffMrSID::GetImageData function method extracts and returns the image data from the MrSID file at the specified level and location.

## Syntax

*Result* = *Obj* -> [IDLffMrSID::]GetImageData ([, LEVEL = *lvl*] [, SUB_RECT = *rect*])

## Return Value

Returns an *n*-by-*w*-by-*h* array containing the image data where *n* is 1 for grayscale or 3 for RGB images, *w* is the width and *h* is the height.

**Note**

The returned image is ordered bottom-up, the first pixel returned is located at the bottom-left corner of the image. This differs from how data is stored in the MrSID file where the image is top-down, meaning the pixel at the start of the file is located at the top-left corner of the image.

## Arguments

None

## Keywords

### LEVEL

Set this keyword to an integer that specifies the level at which to read the image.

If this keyword is not set, the maximum level is used which returns the minimum resolution (see the LEVELS keyword to IDLffMrSID::GetProperty).

### SUB_RECT

Set this keyword to a four-element vector [*x, y, xdim, ydim*] specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle of the MrSID image to return. This is useful for displaying portions of a high-resolution image.

If this keyword is not set, the whole image will be returned. This may require significant memory if a high-resolution image level is selected.

If the sub-rectangle is greater than the bounds of the image at the selected level the area outside the image bounds will be set to black.

**Note**

The elements of SUB_RECT are measured in pixels at the current level. This means the point x = 10, y = 10 at level 1 will be located at x = 20, y = 20 at level 0 and x = 5, y = 5 at level 2.

# Examples

```
PRO MrSID_GetImageData

; Initialize the MrSID file object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))

; Get the range of levels of resolution contained within the file.
oFile -> GetProperty, LEVELS = lvls
PRINT, lvls
; IDL prints, -9, 4

; Get the image data at level 0.
imgDataA = oFile -> GetImageData(LEVEL = 0)
HELP, 'image array data at full resolution', imgDataA
;IDL prints, Array[1, 512, 512] indicating a grayscale 512 x 512
array.

; Display the full resolution image.
oImgA = OBJ_NEW('IDLgrImage', imgDataA)
oModelA = OBJ_NEW('IDLgrModel')
oModelA -> Add, oImgA
XOBJVIEW, oModelA, BACKGROUND = [0,0,0], $
   TITLE = 'Full Resolution Image', /BLOCK

; Get the image data of a higher resolution image,
imgDataB = oFile -> GetImageData(LEVEL = -2)
HELP, imgDataB
; IDL returns [1,2048,2048] indicating a grayscale 2048 x 2048
array.
```

```
; To save processing time, display only a 1024 x 1024 portion of
; the high resolution, using 512,512 as the origin..
imgDataSelect = oFile -> GetImageData(LEVEL = -2,$
   SUB_RECT = [512, 512, 1024, 1024])
oImgSelect = OBJ_NEW('IDLgrImage', imgDataSelect)
oModel = OBJ_NEW('IDLgrModel')
oModel -> Add, oImgSelect

XOBJVIEW, oModel, BACKGROUND = [0,0,0], $
   TITLE = 'Detail of High Resolution Image', /BLOCK

; Clean up object references.
OBJ_DESTROY, [oFile, oImgA, oModelA, oImgSelect, oModel]

END
```

## Version History

Introduced: 5.5

# IDLffMrSID::GetProperty

The IDLffMrSID::GetProperty function method is used to query properties associated with the MrSID image.

## Syntax

*Obj* -> [IDLffMrSID::]GetProperty [, CHANNELS=*nChannels*] [, DIMENSIONS=*Dims*] [, LEVELS=*Levels*] [, PIXEL_TYPE=*pixelType*] [, TYPE=*strType*] [, GEO_VALID=*geoValid*] [, GEO_PROJTYPE=*geoProjType*] [, GEO_ORIGIN=*geoOrigin*] [, GEO_RESOLUTION=*geoRes*]

## Arguments

None

## Keywords

### CHANNELS

Set this keyword to a named variable that will contain the number of image bands. For RGB images this is 3, for grayscale it is 1.

### DIMENSIONS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*width*, *height*] that specifies the dimensions of the MrSID image at level 0 (full resolution).

### LEVELS

Set this keyword equal to a named variable that will contain a two-element long integer array of the form [*minlvl*, *maxlvl*] that specifies the range of levels within the current image. Higher levels are lower resolution. A level of 0 equals full resolution. Negative values specify higher levels of resolution.

### PIXEL_TYPE

Set this keyword to a named variable that will contain the IDL basic type code for a pixel sample. For a list of the data types indicated by each type code, see the “IDL Type Codes” section of the SIZE function.

## TYPE

Set this keyword to a named variable that will contain a string identifying the file format. This should always be MrSID.

## GEO_VALID

Set this keyword to a named variable that will contain a long integer that is set to:

- 1 - If the MrSID image contains valid georeferencing data.
- 0 - If the MrSID image does not contain georeferencing data or the data is in an unsupported format.

**Note**

Always verify that this keyword returns 1 before using the data returned by any other GEO_* keyword.

## GEO_PROJTYPE

Set this keyword to a named variable that will contain an unsigned integer that specifies the geoTIFF projected coordinate system type code. For example, type code 32613 corresponds to PCS_WGS84_UTM_zone_13N.

For more information on the geoTIFF file type and available type codes see:

`http://www.remotesensing.org/geotiff/geotiff.html`

## GEO_ORIGIN

Set this keyword to a named variable that will contain a two-element double precision array of the form [*x*, *y*] that specifies the location of the center of the upper-left pixel.

## GEO_RESOLUTION

Set this keyword to a named variable that will contain a two-element double precision array of the form [*xres*, *yres*] that specifies the pixel resolution.

## Examples

```
PRO MrSID_GetProperty

; Initialize the MrSID object.
oFile = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))

; Get the property information of the MrSID file
oFile -> GetProperty, CHANNELS = chan, LEVELS = $
   lvls, Pixel_Type = pType, TYPE = fileType, GEO_VALID = geoQuery

; Print MrSID file information.
PRINT, 'Number of image channels = ', chan
; IDL returns 1 indicating one image band.

PRINT, 'Range of image levels = ', lvls
; IDL returns -9, 4, the minimum and maximum level values.

PRINT, 'Type code of image pixels = ', pType
; IDL returns 1 indicating byte data type.

PRINT, 'Image file type = ', FileType
; IDL returns "MrSID"

PRINT, 'Result of georeferencing data query = ', geoQuery
; IDL returns 0 indicating that the image does not contain
; georeferencing  data.

; Destroy object references.
OBJ_DESTROY, [oFile]

END
```

## Version History

Introduced: 5.5

# IDLffMrSID::Init

The IDLffMrSID::Init function method initializes an IDLffMrSID object containing the image data from a MrSID image file.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Result* = OBJ_NEW('IDLffMrSID', *Filename*[, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLffMrSID::]Init(*Filename*[, *PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Filename

A scalar string argument containing the full path and filename of a MrSID file to be accessed through this IDLffMrSID object.

**Note**

This is a required argument; it is not possible to create an IDLffMrSID object without specifying a valid MrSID file.

## Keywords

Any property listed under “IDLffMrSID Properties” on page 2630 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Examples

```
oMrSID = OBJ_NEW('IDLffMrSID', FILEPATH('test_gs.sid', $
   SUBDIRECTORY = ['examples', 'data']))
```

## Version History

Introduced: 5.5

# IDLffShape

An IDLffShape object contains geometry, connectivity and attributes for graphics primitives accessed from ESRI Shapefiles. See “Overview of ESRI Shapefiles” on page 2644 for more details on Shapefiles.

## Superclasses

This class has no superclass.

## Creation

See IDLffShape::Init

## Properties

Objects of this class have the following properties. See “IDLffShape Properties” on page 2654 for details on individual properties.

- ATTRIBUTE_INFO
- ATTRIBUTE_NAMES
- DBF_ONLY
- ENTITY_TYPE
- FILENAME
- IS_OPEN
- N_ATTRIBUTES
- N_ENTITIES
- N_RECORDS
- UPDATE

## Methods

This class has the following methods:

- IDLffShape::AddAttribute
- IDLffShape::Cleanup

- IDLffShape::Close
- IDLffShape::DestroyEntity
- IDLffShape::GetAttributes
- IDLffShape::GetEntity
- IDLffShape::GetProperty
- IDLffShape::Init
- IDLffShape::Open
- IDLffShape::PutEntity
- IDLffShape::SetAttributes

## Version History

Introduced: 5.4

# Overview of ESRI Shapefiles

An ESRI Shapefile stores nontopological geometry and attribute information for the spatial features in a data set.

A Shapefile consists of a main file (`.shp`), an index file (`.shx`), and a dBASE table (`.dbf`). For example, the Shapefile “states” would have the following files:

- states.shp
- states.shx
- states.dbf

## Naming Conventions for a Shapefile

All the files that comprise an ESRI Shapefile must adhere to the 8.3 filename convention and must be lower case. The main file, index file, and dBASE file must all have the same prefix. The prefix must start with an alphanumeric character and can contain any alphanumeric, underscore (_), or hyphen (-). The main file suffix must use the `.shp` extension, the index file the `.shx` extension, and the dBASE table the `.dbf` extension.

## Major Elements of a Shapefile

A Shapefile consists of the following elements that you can access through the IDLffShape class:

- Entities
- Attributes

### Entities

The geometry for a feature is stored as a shape comprising a set of vector coordinates (referred to as ‘entities’). The entities in a Shapefile must all be of the same type. The following are the possible types for entities in a Shapefile:

| Shape Type | Type Code |
|---|---|
| Point | 1 |
| PolyLine | 3 |
| Polygon | 5 |

*Table 0-16: Entity Types*

| Shape Type | Type Code |
|---|---|
| MultiPoint | 8 |
| PointZ | 11 |
| PolyLineZ | 13 |
| PolygonZ | 15 |
| MultiPointZ | 18 |
| PointM | 21 |
| PolyLineM | 23 |
| PolygonM | 25 |
| MultiPointM | 28 |
| MultiPatch | 31 |

*Table 0-16: Entity Types (Continued)*

When retrieving entities using the IDLffShape::GetEntity method, an IDL structure is returned. This structure has the following fields:

| Field | Data Type |
|---|---|
| SHAPE_TYPE | IDL_LONG |
| ISHAPE | IDL_LONG |
| BOUNDS | Double[8] |
| N_VERTICES | IDL_LONG |
| VERTICES | Pointer (to Vertices array) |
| MEASURE | Pointer (to Measure array) |
| N_PARTS | IDL_LONG |
| PARTS | Pointer (to Parts array). |
| PART_TYPES | Pointer (to part types) |
| ATTRIBUTES | Pointer to attribute array. |

*Table 0-17: Entity Structure Field Data Types*

The following table describes each field in the structure:

| Field | Description |
|---|---|
| SHAPE_TYPE | The entity type. |
| ISHAPE | The identifier of the specific entity in the shape object. |
| BOUNDS | A bounding box that specifies the range limits of the entity. This eight element array contains the following information:<br>• Index 0 — X minimum value<br>• Index 1 — Y minimum value<br>• Index 2 — Z minimum value (if Z is supported by type)<br>• Index 3 — Measure minimum value (if measure is supported by entity type)<br>• Index4 — X maximum value<br>• Index5 — Y maximum value<br>• Index6 — Z maximum value (if Z is supported by the entity type)<br>• Index7 — Measure maximum value (if measure is supported by entity type)<br>**Note -** If the entity is a point type, the values contained in the bounds array are also the values of the entity. |
| N_VERTICES | The number of vertices in the entity. If this value is one and the entity is a POINT type (POINT, POINTM, POINTZ), the vertices pointer will be set to NULL and the entity value will be maintained in the BOUNDS field. |

*Table 0-18: Entity Structure Field Descriptions*

| Field | Description |
|---|---|
| VERTICES | An IDL pointer that contains the vertices of the entity. This pointer contains a double array that has one of the following formats:<br>• [2, *N*] - If Z data is not present<br>• [3, *N*] - If Z data is present<br>where *N* is the number of vertices. These array formats can be passed to the polygon and polyline objects of IDL Object Graphics.<br>**Note -** This pointer will be null if the entity is a point type, with the values maintained in the BOUNDS array. |
| MEASURE | If the entity has a measure value (this is dependent on the entity type), this IDL pointer will contain a vector array of measure values. The length of this vector is N_VERTICES.<br>**Note -** This pointer will be null if the entity is of type POINTM, with the values contained in the BOUNDS array. |
| N_PARTS | If the values of the entity are separated into parts, the break points are enumerated in the parts array. This field lists the number of parts in this entity. If this value is 0, the entity is one part and the PARTS pointer will be NULL. |
| PARTS | An IDL pointer that contains an array of indices into the vertex/measure arrays. These values represent the start of each part of the entity. The index range of each entity part is defined by the following:<br>• Start = Parts[I]<br>• End = Parts[I+1]-1 or the end of the array |

*Table 0-18: Entity Structure Field Descriptions (Continued)*

| Field | Description |
|---|---|
| PART_TYPES | This IDL pointer is only valid for entities of type MultiPatch and defines the type of the particular part. If the entity type is not MultiPatch, part types are assumed to be type RING (SHPP_RING).<br>**Note -** This pointer is NULL if the entity is not type MultiPatch. |
| ATTRIBUTES | If the attributes for an entity were requested, this field contains an IDL pointer that contains a structure of attributes for the entity. For more information on this structure, see “Attributes” on page 2648. |

*Table 0-18: Entity Structure Field Descriptions (Continued)*

### Attributes

A Shapefile provides the ability to associate information describing each entity (a geometric element) contained in the file. This descriptive information, called attributes, consists of a set of named data elements for each geometric entity contained in the file. The set of available attributes is the same for every entity contained in a Shapefile, with each entity having it’s own set of attribute values.

An attribute consist of two components:

- A name
- A data value

The name consists of an 11 character string that is used to identify the data value. The data value is not limited to any specific format.

The two components that form an attribute are accessed differently using the shape object. To get the name of attributes for the specific file, the ATTRIBUTE_NAMES keyword to the IDLffShape::GetProperty method is used. This returns a string array that contains the names for the attributes defined for the file.

To get the attribute values for an entity, the IDLffShape::GetAttributes method is called or the ATTRIBUTES keyword of the IDLffShape::GetEntity method is set. In each case, the attribute values for the specified entity is returned as an anonymous IDL structure. The numeric order of the fields in the returned structure map to the numeric order of the attributes defined for the file. The actual format of the returned structure is:

ATTRIBUTE_0 : VALUE,

ATTRIBUTE_1 : VALUE,

ATTRIBUTE_2 : VALUE,

...

ATTRIBUTE_<N-1> : VALUE

To access the values in the returned structure, you can either hardcode the structure field names or use the structure indexing feature of IDL.

## Accessing Shapefiles

The following example shows how to access data in a Shapefile. This example sets up a map to display parts of a Shapefile, opens a Shapefile, reads the entities from the Shapefile, and then plots only the state of Colorado:

```
PRO ex_shapefile

DEVICE, RETAIN=2, DECOMPOSED=0
!P.BACKGROUND=255

;Define a color table
r=BYTARR(256) & g=BYTARR(256) & b=BYTARR(256)
r[0]=0 & g[0]=0 & b[0]=0             ;Definition of black
r[1]=100 & g[1]=100 & b[1]=255       ;Definition of blue
r[2]=0 & g[2]=255 & b[2]=0           ;Definition of green
r[3]=255 & g[3]=255 & b[3]=0         ;Definition of yellow
r[255]=255 & g[255]=255 & b[255]=255 ;Definition of white

TVLCT, r, g, b
black=0 & blue=1 & green=2 & yellow=3 & white=255

; Set up map to plot Shapefile on
MAP_SET, /ORTHO,45, -120,  /ISOTROPIC, $
/HORIZON, E_HORIZON={FILL:1, COLOR:blue}, $
/GRID, COLOR=black, /NOBORDER

; Fill the continent boundaries:
MAP_CONTINENTS, /FILL_CONTINENTS, COLOR=green
```

```
; Overplot coastline data:
MAP_CONTINENTS, /COASTS, COLOR=black

; Show national borders:
MAP_CONTINENTS, /COUNTRIES, COLOR=black

;Open the states Shapefile in the examples directory
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

;Get the number of entities so we can parse through them
myshape -> IDLffShape::GetProperty, N_ENTITIES=num_ent

;Parsing through the entities and only plotting the state of
;Colorado
FOR x=1, (num_ent-1) DO BEGIN
   ;Get the Attributes for entity x
   attr = myshape -> IDLffShape::GetAttributes(x)
   ;See if 'Colorado' is in ATTRIBUTE_1 of the attributes for
   ;entity x
   IF attr.ATTRIBUTE_1 EQ 'Colorado' THEN BEGIN
      ;Get entity
      ent = myshape -> IDLffShape::GetEntity(x)
      ;Plot entity
      POLYFILL, (*ent.vertices)[0,*], (*ent.vertices)[1,*],
COLOR=yellow
      ;Clean-up of pointers
      myshape -> IDLffShape::DestroyEntity, ent
   ENDIF
ENDFOR

;Close the Shapefile
OBJ_DESTROY, myshape

END
```

This results in the following:

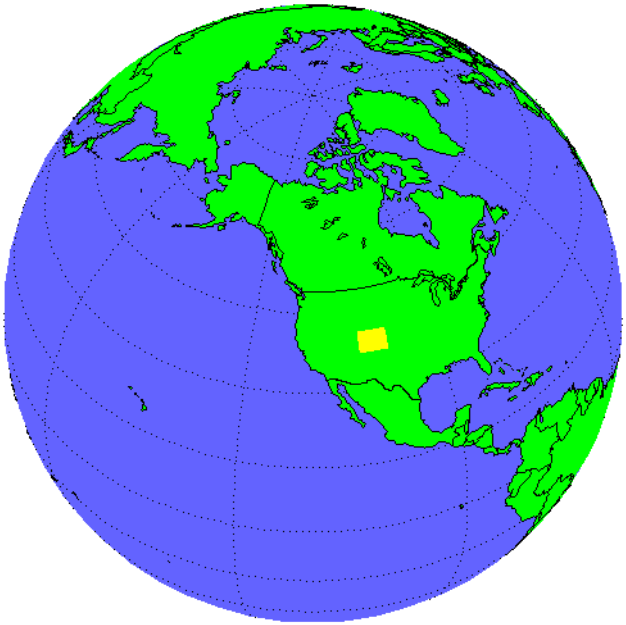

*Figure 0-1: Example Use of Shapefiles*

## Creating New Shapefiles

To create a Shapefile, you need to create a new Shapefile object, define the entity and attributes definitions, and then add your data to the file. For example, the following program creates a new Shapefile (`cities.shp`), defines the entity type to be "Point", defines 2 attributes (CITY_NAME and STATE_NAME), and then adds an entity to the new file:

```
PRO ex_shapefile_newfile

;Create the new shapefile and define the entity type to Point
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)

;Set the attribute definitions for the new Shapefile
mynewshape->IDLffShape::AddAttribute, 'CITY_NAME', 7, 25, $
   PRECISION=0
mynewshape->IDLffShape::AddAttribute, 'STAT_NAME', 7, 25, $
   PRECISION=0
```

```
;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 1458
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

;Create structure for new attributes
attrNew = mynewshape ->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
mynewshape -> IDLffShape::PutEntity, entNew

;Add the Colorado attributes to new shapefile
mynewshape -> IDLffShape::SetAttributes, 0, attrNew

;Close the shapefile
OBJ_DESTROY, mynewshape

END
```

## Updating Existing Shapefiles

You can modify existing Shapefiles with the following:

- Adding new entities
- Adding new attributes (only to Shapefiles without any existing values in any attributes)
- Modifying existing attributes

**Note**

You cannot modify existing entities.

For example, the following program adds an entity and attributes for the city of Boulder to the `cities.shp` file we created in the previous example:

```
PRO ex_shapefile_modify

;Open the cities Shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE)

;Create structure for new entity
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 1380
entNew.BOUNDS[0] = -105.25100
entNew.BOUNDS[1] = 40.026878
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -105.25100
entNew.BOUNDS[5] = 40.026878
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

;Create structure for new attributes
attrNew = myshape ->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

;Define the values for the new attributes
attrNew.ATTRIBUTE_0 = 'Boulder'
attrNew.ATTRIBUTE_1 = 'Colorado'

;Add the new entity to new shapefile
myshape -> IDLffShape::PutEntity, entNew

;Add the Colorado attributes to new shapefile
myshape -> IDLffShape::SetAttributes, 0, attrNew

;Close the shapefile
OBJ_DESTROY, myshape

END
```

# IDLffShape Properties

IDLffShape objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLffShape::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLffShape::Init.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ATTRIBUTE_INFO

A array of structures containing the attribute information for each attribute. The attribute information structures have the following fields:

| Field | Description |
|---|---|
| NAME | A string that contains the name of the attribute. |
| TYPE | The IDL type code of the attribute. |
| WIDTH | The width of the attribute. |
| PRECISION | The precision of the attribute. |

*Table 0-19: ATTRIBUTE_INFO Fields*

The file must be open to obtain this information.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ATTRIBUTE_NAMES

A string array containing the names of each attribute in the Shapefile object.

| **Property Type** | String array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## DBF_ONLY

A non-zero, positive integer value indicating whether the underlying dBASE table (`.dbf`) component of the shapefile is opened while all other entity related files are left closed. The following two values are accepted for this property:

- 1 - Open an existing `.dbf` file,
- Greater than 1 - Create a new `.dbf` file

**Note**

The UPDATE keyword is required to open the `.dbf` file for updating.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## ENTITY_TYPE

If retrieving this property, its value is an integer representing the type code for the entities contained in the Shapefile object. If the value is unknown, this method returns -1. For more information on entity type codes, see “Entities” on page 2644.

If setting this property, its value is an integer representing the entity type of a new Shapefile. Use this setting only when creating a new Shapefile. For more information on entity types, see “Entities” on page 2644.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** No |

## FILENAME

A string representing the fully qualified path name of the Shapefile in the current Shapefile object.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## IS_OPEN

An integer value representing information about the status of a Shapefile. The following values can be returned:

| Value | Description |
|---|---|
| 0 | File is not open. |
| 1 | File is open in read-only mode. |
| 3 | File is open in update mode. |

*Table 0-20: IS_OPEN Values*

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## N_ATTRIBUTES

A longword integer representing the number of attributes associated with a Shapefile object. If the number of attributes is unknown, this property returns 0.

| | | | |
|---|---|---|---|
| **Property Type** | Long | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## N_ENTITIES

A longword integer representing the number of entities contained in Shapefile object. If the number of entities is unknown, this property returns 0.

| | | | |
|---|---|---|---|
| **Property Type** | Long | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## N_RECORDS

A longword integer representing the number of records in the dBASE table (`.dbf`) component of the Shapefile. In a normal operating mode, this process is accomplished by getting the number of entities. However, in DBF_ONLY mode, no entity file exits.

| | | | |
|---|---|---|---|
| **Property Type** | Long | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## UPDATE

A Boolean value indicating whether the file opened for writing. The file is opened for writing if this property is set to true. The default is read-only.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLffShape::AddAttribute

The IDLffShape::AddAttribute method adds an attribute definition to a Shapefile. Adding a the attribute definition is required before adding the actual attribute data to a file. For more information on attributes, see “Attributes” on page 2648.

**Note**

You can only define new attributes to Shapefiles that do not have any existing values in any attributes.

# Syntax

*Obj*->[IDLffShape::]AddAttribute, *Name*, *Type*, *Width* [, PRECISION=*integer*]

# Arguments

## Name

Set to a string that contains the attribute name. Name values are limited to 11 characters. Arguments longer than 11 characters will be truncated.

## Type

Set to the IDL type code that corresponds to the data type that will be stored in the attribute. The valid types are:

| Code | Description |
|---|---|
| 3 | Longword Integer |
| 5 | Double-precision floating-point |
| 7 | String |

*Table 0-21: Type Code Descriptions*

### Width

Set to the width of the field for the data value of the attribute. The following table describes the possible values depending on the defined Type:

| Field Type | Valid Values |
|---|---|
| Longword Integer | Maximum size of the field. |
| Double-precision floating-point | Maximum size of the field. |
| String | Maximum length of the string. |

*Table 0-22: Width Values*

## Keywords

### PRECISION

Set this keyword to the number of positions to be included after the decimal point. The default is 8. This keyword is only valid for fields defined as double-precision floating-point.

## Examples

In the following example, we add the attribute “ELEVATION” to an existing Shapefile. Note that if the file already contains data in an attribute for any of the entities defined in the file, this operation will fail.

```
PRO ex_addattr_shapefile

;Open a shapefile
myshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE)

;Define a new attribute for the Shapefile
myshape->IDLffShape::AddAttribute, 'ELEVATION', 3, 4, $
   PRECISION=0

;Close the shapefile
OBJ_DESTROY, myshape

END
```

## Version History

Introduced: 5.4

# IDLffShape::Cleanup

The IDLffShape::Cleanup procedure method performs all cleanup on a Shapefile object. If the Shapefile being accessed by the object is open and the file has been modified, the new information is written to the file if one of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

**Note**

Cleanup methods are special lifecycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLffShape::]Cleanup (Only in subclass' Cleanup method.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.4

# IDLffShape::Close

The IDLffShape::Close procedure method closes a Shapefile. If the file has been modified, it is also written to the disk if neither of the following conditions is met:

- The file was opened with write permissions using the UPDATE keyword to the IDLffShape::Open method
- It is a newly created file that has not been written previously.

If the file has been modified and one of the previous conditions is not met, the file is closed and the changes are not written to disk.

## Syntax

*Obj* -> [IDLffShape::]Close

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.4

# IDLffShape::DestroyEntity

The IDLffShape::DestroyEntity procedure method frees memory associated with the entity structure. For more information on the entity structure, see “Entities” on page 2644.

## Syntax

*Obj* -> [IDLffShape::]DestroyEntity, *Entity*

## Arguments

### Entity

A scalar or array of entities to be destroyed.

## Keywords

None

## Examples

In the following example, all of the entities from the `states.shp` Shapefile are read and then the DestroyEntity method is called to clean up all pointers:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape -> IDLffShape::GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
   ;Read the entity x
   ent = myshape -> IDLffShape::GetEntity(x)
   ;Clean-up of pointers
   myshape -> IDLffShape::DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape
```

```
END
```

## Version History

Introduced: 5.4

# IDLffShape::GetAttributes

The IDLffShape::GetAttributes function method retrieves the attributes for the entities you specify from a Shapefile.

## Syntax

*Result* = *Obj* -> [IDLffShape::]GetAttributes([*Index*] [, /ALL] [, /ATTRIBUTE_STRUCTURE] )

## Return Value

Returns an anonymous structure array. For more information on the structure, see "Attributes" on page 2648.

## Arguments

### Index

A scalar or array of longs specifying the entities for which you want to retrieve the attributes, with 0 being the first entity in the Shapefile.

**Note**

If you do not specify *Index* and the ALL keyword is not set, the attributes for the first entity (0) are returned.

## Keywords

### ALL

Set this keyword to retrieve the attributes for all entities in a Shapefile. If you set this keyword, the *Index* argument is not required.

### ATTRIBUTE_STUCTURE

Set this keyword to return an empty attribute structure that can then be used with the IDLffShape::SetAttributes method to add attributes to a Shapefile.

## Examples

In the first example, we retrieve the attributes associated with entity at location 0 (the first entity in the file):

```
attr = myShape->getAttributes( 0)
```

In the next example, we retrieve the attributes associated with entities 10 through 20:

```
attr = myShape->getAttributes( 10+indgen(11) )
```

In the next example, we retrieve the attributes for entities 1,4, 9 and 70:

```
attr = myShape->getAttributes( [1, 4, 9, 70] )
```

In the next example, we retrieve all the attributes for a Shapefile:

```
attr = myShape->getAttributes( /ALL )
```

## Version History

Introduced: 5.4

# IDLffShape::GetEntity

The IDLffShape::GetEntity function method returns the entities you specify from a Shapefile.

## Syntax

*Result* = *Obj* -> [IDLffShape::]GetEntity([*Index*] [, /ALL] [, /ATTRIBUTES])

## Return Value

Returns a type {IDL_SHAPE_ENTITY} structure array. For more information on the structure, see “Entities” on page 2644.

**Note**

Since an entity structure contains IDL pointers, you must free all the pointers returned in these structures when the entity is no longer needed using the IDLffShape::DestroyEntity method.

**Note**

Since entities cannot be modified in a Shapefile, an entity is read directly from the Shapefile each time you use the IDLffShape::GetEntity method even if you have already read that entity. If you modify the structure array returned by this method for a given entity and then use IDLffShape::GetEntity on that same entity, the modified data will NOT be returned, the data that is actually written in the file is returned.

## Arguments

### Index

A scalar or array of longs specifying the entities for which you want to retrieve with 0 being the first entity in the Shapefile. If the ALL keyword is set, this argument is not required. If you do not specify any entities and the ALL keyword is not set, the first entity (0) is returned.

# Keywords

## ALL

Set this keyword to retrieve all entities from the Shapefile. If this keyword is set, the Index argument is not required.

## ATTRIBUTES

Set this keyword to return the attributes in the entity structure. If not set, the ATTRIBUTES tag in the entity structure will be a null IDL pointer.

# Examples

In the following example, all of the entities from the `states.shp` Shapefile are read:

```
PRO ex_shapefile

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the number of entities so we can parse through them.
myshape -> IDLffShape::GetProperty, N_ENTITIES=num_ent

; Read all the entities.
FOR x=1, (num_ent-1) DO BEGIN
   ;Read the entity x
   ent = myshape -> IDLffShape::GetEntity(x)
   ;Clean-up of pointers
   myshape -> IDLffShape::DestroyEntity, ent
ENDFOR

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

# Version History

Introduced: 5.4

# IDLffShape::GetProperty

The IDLffShape::GetProperty procedure method returns the values of properties associated with a Shapefile object. These properties are:

- Number of entities
- The type of the entities
- The number of attributes associated with each entity
- The names of the attributes
- The name, type, width, and precision of the attributes
- The status of a Shapefile
- The filename of the Shapefile object

## Syntax

*Obj* -> [IDLffShape::]GetProperty [, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLffShape Properties” on page 2654 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Examples

In the following example, the number of entities and the entity type is returned:

```
PRO entity_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the number of entities and the entity type.
myshape -> IDLffShape::GetProperty, N_ENTITIES=num_ent, $
   ENTITY_TYPE=ent_type
```

```
; Print the number of entities and the type.
PRINT, 'Number of Entities: ', num_ent
PRINT, 'Entity Type: ', ent_type

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

This results in the following:

```
Number of Entities:       51
Entity Type:               5
```

In the next example, the definitions for attribute 1 are returned:

```
PRO attribute_info

; Open the states Shapefile in the examples directory.
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))

; Get the info for all attribute.
myshape -> IDLffShape::GetProperty, ATTRIBUTE_INFO=attr_info

; Print Attribute Info.
PRINT, 'Attribute Number: ', '1'
PRINT, 'Attribute Name: ', attr_info[1].name
PRINT, 'Attribute Type: ', attr_info[1].type
PRINT, 'Attribute Width: ', attr_info[1].width
PRINT, 'Attribute Precision: ', attr_info[1].precision

; Close the Shapefile.
OBJ_DESTROY, myshape

END
```

This results in the following:

```
Attribute Number:           1
Attribute Name:    STATE_NAME
Attribute Type:             7
Attribute Width:           25
Attribute Precision:        0
```

## Version History

Introduced: 5.4

N_RECORDS keyword: 5.6

# IDLffShape::Init

The IDLffShape::Init function method initializes or constructs a Shapefile object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Result* = OBJ_NEW('IDLffShape' [, *Filename*] [, *PROPERTY=value*])

or

*Result = Obj* `->` [IDLffShape::]Init([, *Filename*] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Filename

A scalar string containing the full path and filename of a Shapefile (`.shp`) to open. If this file exists, it is opened. If the file does not exist, a new Shapefile object is constructed. You do not need to use IDLffShape::Open to open an existing file when specifying this keyword.

**Note**

The `.shp`, `.shx`, and `.dbx` files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

## Keywords

Any property listed under “IDLffShape Properties” on page 2654 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Examples

In the following example, we create a new Shapefile object and open the `examples/data/states.shp` file:

```
myshape=OBJ_NEW('IDLffShape', FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']))
```

## Version History

Introduced: 5.4

DBF_ONLY keyword: 5.6

# IDLffShape::Open

The IDLffShape::Open function method opens a specified Shapefile.

## Syntax

*Result* = *Obj* -> [IDLffShape::]Open( *'Filename'* [, /DBF_ONLY] [, /UPDATE] [, ENTITY_TYPE=*'value'*] )

## Return Value

Returns 1 if the file can be read successfully. If not able to open the file, it returns 0.

## Arguments

### Filename

A scalar string containing the full path and filename of a Shapefile (`.shp`) to open. Note that the `.shp`, `.shx`, and `.dbx` files must exist in the same directory for you to be able to open and access the file unless the UPDATE keyword is set.

## Keywords

### DBF_ONLY

If this keyword is set to a positive value, only the underlying dBASE table (`.dbf`) component of the shapefile is opened. All entity related files are left closed. Two values to this keyword are accepted: 1 - Open an existing `.dbf` file, > 1 - Create a new `.dbf` file

The UPDATE keyword is required to open the `.dbf` file for updating.

### UPDATE

Set this keyword to have the file opened for writing. The default is read-only.

### ENTITY_TYPE

Set this keyword to the entity type of a new Shapefile. Use this keyword only when creating a new Shapefile. For more information on entity types, see "Entities" on page 2644.

## Examples

In the following example, the file `examples/data/states.shp` is opened for reading and writing:

```
status = myShape->Open(FILEPATH('states.shp', $
   SUBDIR=['examples', 'data']), /UPDATE)
```

## Version History

Introduced: 5.4

DBF_ONLY keyword: 5.6

# IDLffShape::PutEntity

The IDLffShape::PutEntity procedure method inserts an entity into the Shapefile object. The entity must be in the proper structure. For more information on the structure, see “Entities” on page 2644.

**Note**

The shape type of the new entity must be the same as the shape type defined for the Shapefile. If the shape type has not been defined for the Shapefile using the ENTITY_TYPE keyword for the IDLffShape::Open or IDLffShape::Init methods, the first entity that is inserted into the Shapefile defines the type.

**Note**

Only new entities can be inserted into a Shapefile. Existing entities cannot be updated.

## Syntax

*Obj* -> [IDLffShape::]PutEntity, *Data*

## Arguments

### Data

A scalar or an array of entity structures.

## Keywords

None

## Examples

In the following example, we create a new shapefile, define a new entity, and then use the PutEntity method to insert it into the new file:

```
PRO ex_shapefile_newfile

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)
```

```
; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity.
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 1458
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Add the new entity to new shapefile.
mynewshape -> IDLffShape::PutEntity, entNew

; Close the shapefile.
OBJ_DESTROY, mynewshape

END
```

## Version History

Introduced: 5.4

# IDLffShape::SetAttributes

The IDLffShape::SetAttributes procedure method sets the attributes for a specified entity in a Shapefile object.

## Syntax

*Obj* -> [IDLffShape::]SetAttributes, *Index*, *Attribute_Num*, *Value*

or

*Obj* -> [IDLffShape::]SetAttributes, *Index*, *Attributes*

## Arguments

### Attribute_Num

The field number for the attribute whose value is being set. This value is 0-based.

### Attributes

An Attribute structure whose fields match the fields in the attribute table. If *Attributes* is an array, the entities specified in *Index*, up to the size of the Attributes array, are set. Using this feature, all the attribute values of a set of entities can be set for a Shapefile.

The type of this Attribute structure must match the type that is generated internally for Attribute table. To get a copy of this structure, either get the attribute set for an entity or get the definition using the ATTRIBUTE_STRUCTURE keyword of the IDLffShape::GetProperty method.

### Index

A scalar specifying the entity in which you want to set the attributes. The first entity in the Shapefile object is 0.

### Value

The value that the attribute is being set to. If the value is not of the correct type, type conversion is attempted.

If *Value* is an array and *Index* is a scalar, the value of record is treated as a starting point. Using this feature, all the attribute values of a specific field can be set for a Shapefile.

## Keywords

None

## Examples

In the following example, we create a new shapefile, define the attributes for the new file, define a new entity, define some attributes, insert the new entity, and then use the SetAttributes method to insert the attributes into the new file:

```
PRO ex_shapefile_newfile

; Create the new shapefile and define the entity type to Point.
mynewshape=OBJ_NEW('IDLffShape', FILEPATH('cities.shp', $
   SUBDIR=['examples', 'data']), /UPDATE, ENTITY_TYPE=1)

; Set the attribute definitions for the new Shapefile.
mynewshape->IDLffShape::AddAttribute, 'CITY_NAME', 7, 25, $
   PRECISION=0
mynewshape->IDLffShape::AddAttribute, 'STAT_NAME', 7, 25, $
   PRECISION=0

; Create structure for new entity.
entNew = {IDL_SHAPE_ENTITY}

; Define the values for the new entity
entNew.SHAPE_TYPE = 1
entNew.ISHAPE = 1458
entNew.BOUNDS[0] = -104.87270
entNew.BOUNDS[1] = 39.768040
entNew.BOUNDS[2] = 0.00000000
entNew.BOUNDS[3] = 0.00000000
entNew.BOUNDS[4] = -104.87270
entNew.BOUNDS[5] = 39.768040
entNew.BOUNDS[6] = 0.00000000
entNew.BOUNDS[7] = 0.00000000

; Create structure for new attributes.
attrNew = mynewshape ->IDLffShape::GetAttributes( $
/ATTRIBUTE_STRUCTURE)

; Define the values for the new attributes.
attrNew.ATTRIBUTE_0 = 'Denver'
attrNew.ATTRIBUTE_1 = 'Colorado'

; Add the new entity to new shapefile.
mynewshape -> IDLffShape::PutEntity, entNew
```

```
; Add the Colorado attributes to new shapefile.
mynewshape -> IDLffShape::SetAttributes, 0, attrNew

; Close the shapefile.
OBJ_DESTROY, mynewshape

END
```

## Version History

Introduced: 5.4

# IDLffXMLSAX

An IDLffXMLSAX object uses an XML SAX level 2 parser. The XML parser allows you to read an XML file and store arbitrary data from the file in IDL variables. The parser object's methods are *callbacks*. These methods are called automatically when the parser encounters different types of XML elements or attributes.

**Note**

To use the XML parser, you *must* write a subclass of this object class, overriding the object methods as necessary to process the data in a specific XML file or files. See Chapter 23, "Using the XML Parser Object Class" in the *Building IDL Applications* manual for further information and examples.

The IDLffXMLSAX object encapsulates the Xerces validating XML parser; see `http://xml.apache.org` for details.

## Superclasses

This class has no superclass.

## Subclasses

You *must* write a subclass of this object, overriding object methods as necessary to retrieve information from the XML file.

## Creation

See "IDLffXMLSAX::Init" on page 2705

## Properties

Objects of this class have the following properties. See "IDLffXMLSAX Properties" on page 2683 for details on individual properties.

- FILENAME
- NAMESPACE_PREFIXES
- PARSER_LOCATION
- PARSER_PUBLICID
- PARSER_URI

- SCHEMA_CHECKING
- VALIDATION_MODE

## Methods

This class has the following methods:

- IDLffXMLSAX::AttributeDecl
- IDLffXMLSAX::Characters
- IDLffXMLSAX::Cleanup
- IDLffXMLSAX::Comment
- IDLffXMLSAX::ElementDecl
- IDLffXMLSAX::EndCDATA
- IDLffXMLSAX::EndDocument
- IDLffXMLSAX::EndDTD
- IDLffXMLSAX::EndElement
- IDLffXMLSAX::EndEntity
- IDLffXMLSAX::EndPrefixMapping
- IDLffXMLSAX::Error
- IDLffXMLSAX::ExternalEntityDecl
- IDLffXMLSAX::FatalError
- IDLffXMLSAX::GetProperty
- IDLffXMLSAX::IgnorableWhitespace
- IDLffXMLSAX::Init
- IDLffXMLSAX::InternalEntityDecl
- IDLffXMLSAX::NotationDecl
- IDLffXMLSAX::ParseFile
- IDLffXMLSAX::ProcessingInstruction
- IDLffXMLSAX::SetProperty
- IDLffXMLSAX::SkippedEntity
- IDLffXMLSAX::StartCDATA

- IDLffXMLSAX::StartDocument
- IDLffXMLSAX::StartDTD
- IDLffXMLSAX::StartElement
- IDLffXMLSAX::StartEntity
- IDLffXMLSAX::StartPrefixmapping
- IDLffXMLSAX::StopParsing
- IDLffXMLSAX::UnparsedEntityDecl
- IDLffXMLSAX::Warning

## Version History

Introduced: 5.6

# IDLffXMLSAX Properties

IDLffXMLSAX objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLffXMLSAX::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLffXMLSAX::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLffXMLSAX::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## FILENAME

A string containing the filename of the XML file being parsed.

**Note**

This property is only available during a parse operation.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## NAMESPACE_PREFIXES

A Boolean value indicating whether namespace prefixes are enabled. Namespace prefixes are enabled if this property is set to true. By default, namespace prefixes are disabled.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PARSER_LOCATION

A two-element array containing the approximate location of the parser within the entity being parsed. The first element of the array is set to the line number and the second element is set to the column number.

**Note**

This property is only available during a parse operation

| | | | |
|---|---|---|---|
| **Property Type** | Array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## PARSER_PUBLICID

A string containing the Public ID for the entity being parsed, if it is available. If the Public ID is not available, an empty string is returned.

**Note**

This property is only available during a parse operation

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## PARSER_URI

A string containing the base URI (System ID) for the entity being parsed, if it is available. If the value is available, it is always an absolute URI. If the System ID is not available, an empty string is returned.

**Note**

This property can be used to identify the document or external entity in diagnostics, or to resolve relative URIs. However, it is only available during a parse operation.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## SCHEMA_CHECKING

An integer value to indicating the type of validation the parser should perform. XML *Schemas* describe the structure and allowed contents of an XML document. Schemas are more robust than, and are envisioned as a replacement for, DTDs. By default, the parser will validate the parsed XML file against the specified schema, if one is provided. If no schema is provided, no validation will occur. Possible values are:

| Value | Description |
|---|---|
| 0 | No validation. |
| 1 | Validate only if a schema is provided (the default). |
| 2 | Perform full schema constraint checking, if a schema is provided. This feature checks the schema grammar itself for additional errors. It does not affect the level of checking performed on document instances that use schema grammars. |

*Table 0-23: SCHEMA_CHECKING Values*

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## VALIDATION_MODE

An integer value indicating the type of XML validation that the parser should perform. XML *Document Type Definitions* (DTDs) describe the structure and allowed contents of an XML document. By default, the parser will validate the parsed XML file against the specified DTD, if one is provided; if no DTD is provided, no validation will occur. Possible values are:

| Value | Description |
|---|---|
| 0 | No validation. |
| 1 | Validate only if a DTD is provided (the default). |

*Table 0-24: VALIDATION_MODE Values*

| Value | Description |
|---|---|
| 2 | Always perform validation. If this option is in force and no DTD is provided, every XML element in the document will generate an error. |

*Table 0-24: VALIDATION_MODE Values*

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLffXMLSAX::AttributeDecl

The IDLffXMLSAX::AttributeDecl procedure method is called when the parser detects an `<!ATTLIST ...>` declaration in a DTD. This method is called once for each attribute declared by the tag.

## Syntax

*Obj* -> [IDLffXMLSAX::]AttributeDecl, *eName, aName, Type, Mode, Value*

## Arguments

### eName

A string containing the name of the element for which the attribute is being declared.

### aName

A string containing the name of the attribute being declared.

### Type

A string that specifying the type of attribute being defined. Possible values are:

- 'CDATA'
- 'ID'
- 'IDREF'
- 'IDREFS'
- 'NMTOKEN'
- 'NMTOKENS'
- 'ENTITY'
- 'ENTITIES'

or two types of enumerated values. Enumerated values are encoded with parenthesized strings such as `(a|b|c)` to indicate that strings `a`, `b`, or `c` are permissible. If the string is an enumeration of notation names, the string `"NOTATION "` (note the space after the second “N”) precedes the parenthesized string.

### Mode

A string specifying restrictions on the value of the attribute. Possible values are:

- '#IMPLIED' - the application determines the value
- '#REQUIRED' - the value must be given; defaulting is not permitted
- '#FIXED' - only one value is permitted
- '' - a null string (the value specified by the *Value* argument is used as the default)

### Value

A string containing the default value for the attribute. If *Value* contains a null string, no default value was specified.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::Characters

The IDLffXMLSAX::Characters procedure method is called when the parser detects text in the parsed document.

## Syntax

*Obj* -> [IDLffXMLSAX::]Characters, *Chars*

## Arguments

### Chars

A string containing the text detected by the parser.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::Cleanup

The IDLffXMLSAX::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. In most cases, you cannot call the Cleanup method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLffXMLSAX::]Cleanup(*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::Comment

The IDLffXMLSAX::Comment procedure method is called when the parser detects a comment section of the form <!-- ... -->.

## Syntax

*Obj* -> [IDLffXMLSAX::]Comment, *Comment*

## Arguments

### Comment

A string containing the text within the detected comment section, without the delimiting characters ("<!--" and "-->").

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::ElementDecl

The IDLffXMLSAX::ElementDecl procedure method is called when the parser detects an `<!ELEMENT ...>` declaration in the DTD.

## Syntax

*Obj* `->` [IDLffXMLSAX::]ElementDecl, *Name*, *Model*

## Arguments

### Name

A string containing the name of the element.

### Model

A string containing the *content model* (sometimes called the *content specification*) for the element, with all whitespace removed.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::EndCDATA

The IDLffXMLSAX::EndCDATA procedure method is called when the parser detects the end of a `<![CDATA[...]]>` text section.

## Syntax

*Obj* `->` [IDLffXMLSAX::]EndCDATA

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::EndDocument

The IDLffXMLSAX::EndDocument procedure method is called when the parser detects the end of the XML document.

## Syntax

*Obj* -> [IDLffXMLSAX::]EndDocument

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::EndDTD

The IDLffXMLSAX::EndDTD procedure method is called when the parser detects the end of a Document Type Definition (DTD).

## Syntax

*Obj* -> [IDLffXMLSAX::]EndDTD

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::EndElement

The IDLffXMLSAX::EndElement procedure method is called when the parser detects the end of an element.

## Syntax

*Obj* -> [IDLffXMLSAX::]EndElement, *URI*, *Local*, *qName*

## Arguments

### URI

A string containing the namespace URI with which the element is associated, if any.

**Note**

A URI (or Uniform Resource Identifier) refers to the generic set of all names and addresses which are short strings which refer to objects.

### Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

### qName

A string containing the element name found in the XML file.

**Note**

If the element is associated with a namespace URI, this variable may contain an empty string.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::EndEntity

The IDLffXMLSAX::EndEntity procedure method is called when the parser detects the end of an internal or external entity expansion.

## Syntax

*Obj* -> [IDLffXMLSAX::]EndEntity, *Name*

## Arguments

### Name

A string containing the name of the entity.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::EndPrefixMapping

The IDLffXMLSAX::EndPrefixMapping procedure method is called when a previously declared prefix mapping goes out of scope.

## Syntax

*Obj* -> [IDLffXMLSAX::]EndPrefixMapping, *Prefix*

## Arguments

### Prefix

A string containing the namespace prefix that is going out of scope.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::Error

The IDLffXMLSAX::Error procedure method is called when the parser detects an error that is not expected to be fatal. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

For example, a violation of XML validity constraints is generally a non-fatal error.

**Note**

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

# Syntax

*Obj* -> [IDLffXMLSAX::]Error, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

# Arguments

## SystemID

A string containing the URI of the associated text.

## LineNumber

A longword integer representing the line number that contains the error.

## ColumnNumber

A longword integer representing the column number that contains the error.

## Message

A string containing the error message sent to the IDL output log.

# Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::ExternalEntityDecl

The IDLffXMLSAX::ExternalEntityDecl procedure method is called when the parser detects an `<!ENTITY ...>` declarations in the DTD for a parsed external entity.

## Syntax

*Obj* `->` [IDLffXMLSAX::]ExternalEntityDecl, *Name*, *PublicID*, *SystemID*

## Arguments

### Name

A string containing the entity name.

### PublicID

A string containing the Public ID for the entity.

**Note**

If this value is not specified in the entity declaration, this variable will contain an empty string.

### SystemID

A string containing the System ID for the entity, provided as an absolute URI.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::FatalError

The IDLffXMLSAX::FatalError procedure method is called when the parser detects a fatal error. When called, parsing will normally stop, but may sometimes continue long enough to report further errors. This method prints an IDL error string to the IDL output log.

## Syntax

*Obj* -> [IDLffXMLSAX::]FatalError, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

## Arguments

### SystemID

A string containing the URI of the associated text.

### LineNumber

A longword integer representing the line number that contains the error.

### ColumnNumber

A longword integer representing the column number that contains the error.

### Message

A string containing the error message sent to the IDL output log.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::GetProperty

The IDLffXMLSAX::GetProperty procedure method is used to get the values of various properties of the parser.

## Syntax

*Obj* -> [IDLffXMLSAX::]GetProperty [, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLffXMLSAX Properties” on page 2683 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 5.6

# IDLffXMLSAX::IgnorableWhitespace

The IDLffXMLSAX::IgnorableWhitespace procedure method is called when the parser detects whitespace that separates elements in an element content model.

## Syntax

*Obj* -> [IDLffXMLSAX::]IgnorableWhitespace, *Chars*

## Arguments

### Chars

A string containing the whitespace detected by the parser. Whitespace can consist of spaces, tabs, or newline characters in any combination.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::Init

The IDLffXMLSAX::Init function method initializes an XML parser object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. In most cases, you cannot call the Init method directly. However, one exception to this rule does exist. If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLffXMLSAX' [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLffXMLSAX::]Init([*PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLffXMLSAX Properties" on page 2683 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.6

# IDLffXMLSAX::InternalEntityDecl

The IDLffXMLSAX::InternalEntityDecl procedure method is called when the parser detects an `<!ENTITY ...>` declaration in a DTD for (parsed) internal entities. The entity can be either a general entity or a parameter entity.

## Syntax

*Obj* `->` [IDLffXMLSAX::]InternalEntityDecl, *Name*, *Value*

## Arguments

### Name

A string containing the entity name. Names that start with the "%" character are parameter entities; all others are general entities.

### Value

A string containing the entity value. The entity value can contain arbitrary XML content, which will be reparsed when the entity is expanded.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::NotationDecl

The IDLffXMLSAX::NotationDecl procedure method is called when the parser detects a `<!NOTATION ...>` declaration in a DTD.

## Syntax

*Obj* `->` [IDLffXMLSAX::]NotationDecl, *Name*, *PublicID*, *SystemID*

## Arguments

### Name

A string containing the notation name.

### PublicID

A string containing the Public ID for the notation.

**Note**

If this value is not specified in the notation declaration, this variable will contain an empty string.

### SystemID

A string containing the System ID for the notation, provided as an absolute URI.

**Note**

If this value is not specified in the notation declaration, this variable will contain an empty string.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::ParseFile

The IDLffXMLSAX::ParseFile procedure method parses the specified XML file. During the parsing operation, different object methods are called as different items within the XML file are detected. When this method returns, the parse operation is complete.

## Syntax

*Obj* -> [IDLffXMLSAX::]ParseFile, *Filename*

## Arguments

### Filename

A string containing the full path name of the XML file to parse.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::ProcessingInstruction

The IDLffXMLSAX::ProcessingInstruction procedure method is called when the parser detects a processing instruction.

## Syntax

*Obj* -> [IDLffXMLSAX::]ProcessingInstruction, *Target*, *Data*

## Arguments

### Target

A string specifying the target, which is the application that should process the instruction.

### Data

A string specifying the data to be passed to the application specified by *Target*.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::SetProperty

The IDLffXMLSAX::SetProperty procedure method is used to set the values of various properties of the parser.

## Syntax

*Obj* -> [IDLffXMLSAX::]SetProperty [, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLffXMLSAX Properties” on page 2683 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.6

# IDLffXMLSAX::SkippedEntity

The IDLffXMLSAX::SkippedEntity procedure method is called when the parser skips an entity and validation is not being performed. This method is rarely called by SAX parsers.

## Syntax

*Obj* -> [IDLffXMLSAX::]SkippedEntity, *Name*

## Arguments

### Name

A string containing the name of the entity that was skipped.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::StartCDATA

The IDLffXMLSAX::StartCDATA procedure method is called when the parser detects the beginning of a `<![CDATA[...]]>` text section.

## Syntax

*Obj* `->` [IDLffXMLSAX::]StartCDATA

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::StartDocument

The IDLffXMLSAX::StartDocument procedure method is called when the parser begins processing a document, and before any data is processed.

## Syntax

*Obj* -> [IDLffXMLSAX::]StartDocument

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::StartDTD

The IDLffXMLSAX::StartDTD procedure method is called when the parser detects the beginning of a Document Type Definition (DTD).

## Syntax

*Obj* -> [IDLffXMLSAX::]StartDTD, *Name*, *PublicID*, *SystemID*

## Arguments

### Name

A string containing the declared name of the root element for the document.

### PublicID

A string containing the *normalized* version of the Public ID (a URI) declared for the external subset, or an empty string if no external subset was declared. *Normalization* involves removal of unnecessary “.” and “..” segments from the URI.

### SystemID

A string containing the System ID (a URI) of the external subset, or an empty string if no external subset was declared.

**Note**

This URI has not been resolved into an absolute URI.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::StartElement

The IDLffXMLSAX::StartElement procedure method is called when the parser detects the beginning of an element.

## Syntax

*Obj* -> [IDLffXMLSAX::]StartElement, *URI*, *Local*, *qName* [, *attName*, *attValue*]

## Arguments

### URI

A string containing the namespace URI with which the element is associated, if any.

### Local

A string containing the element name with any prefix removed, if the element is associated with a namespace URI. If the element is not associated with a namespace URI, this variable will contain an empty string.

### qName

A string containing the element name found in the XML file.

**Note**

If the element is associated with a namespace URI, this variable may contain an empty string.

### attrName

A string array representing the names of the attributes associated with the element, if any.

### attrValue

A string array representing the values of each attribute associated with the element, if any. The returned array will have the same number of elements as the array returned in the *attrName* keyword variable.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::StartEntity

The IDLffXMLSAX::StartEntity procedure method is called when the parser detects the start of an internal or external entity expansion.

## Syntax

*Obj* -> [IDLffXMLSAX::]StartEntity, *Name*

## Arguments

### Name

A string containing the name of the entity.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::StartPrefixmapping

The IDLffXMLSAX::StartPrefixMapping procedure method is called when the parser detects the beginning of a namespace declaration.

## Syntax

*Obj* -> [IDLffXMLSAX::]StartPrefixmapping, *Prefix*, *URI*

## Arguments

### Prefix

A string containing the prefix, which is being mapped. If the variable specified by *Prefix* contains an empty string, the mapping is for the default element namespace.

### URI

A string containing the URI of the prefix namespace.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::StopParsing

Call the IDLffXMLSAX::StopParsing procedure method during a parse operation to halt the operation and cause the ParseFile method to return. This may be useful when parsing large XML files and the desired information is known to have been returned.

## Syntax

*Obj* -> [IDLffXMLSAX::]StopParsing

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::UnparsedEntityDecl

The IDLffXMLSAX::UnparsedEntityDecl procedure method is called when the parser detects an `<!ENTITY ...>` declaration that includes the NDATA keyword, indicating that the entity is not meant to be parsed. The value of the NDATA keyword generally specifies the name of a *notation*, which in turn specifies the type of data.

## Syntax

*Obj* `->` [IDLffXMLSAX::]UnparsedEntityDecl, *Name*, *PublicID*, *SystemID*, *Notation*

## Arguments

### Name

A string containing the name of the unparsed entity.

### PublicID

A string containing the Public ID of the notation specified by the entity's NDATA keyword, or an empty string if no Public ID was declared.

### SystemID

A string containing the System ID of the notation specified by the entity's NDATA keyword. This value is normally an absolute URI.

### Notation

A string containing the name of the notation specified by the entity's NDATA keyword.

## Keywords

None

## Version History

Introduced: 5.6

# IDLffXMLSAX::Warning

The IDLffXMLSAX::Warning procedure method is called when the parser detects a problem during processing. This method prints an IDL error string to the IDL output log and allows the parser to continue processing.

**Note**

This method will cause error messages to be printed to the IDL output log. If you would like your application to hide error messages from the user (or display them in some other fashion), override this method in your subclass of the IDLffXMLSAX object class. If you do override this method, the error message will not be printed to the output log unless you explicitly call the superclass method.

# Syntax

*Obj* -> [IDLffXMLSAX::]Warning, *SystemID*, *LineNumber*, *ColumnNumber*, *Message*

# Arguments

## SystemID

A string containing the URI of the text that generated the error.

## LineNumber

A longword integer representing the line number that contains the error.

## ColumnNumber

A longword integer representing the column number that contains the error.

## Message

A string containing the error message.

# Chapter 7: iTools Object Classes

This chapter describes IDL's built-in annotation class library.

# IDLitCommand

The IDLitCommand class provides a dynamic data dictionary storage system. Its methods and properties allow the iTool developer to store information about the execution of an iTool operation on a single target object. It provides a tag-based mechanism for storing and retrieving this information, which allows the iTool developer to easily implement undo and redo functionality for an operation.

This class is written in the IDL language. Its source code can be found in the file `idlitcommand__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitComponent

## Creation

See "IDLitCommand::Init" on page 2734.

## Properties

Objects of this class have the following properties. See "IDLitCommand Properties" on page 2727 for details on individual properties.

- TARGET_IDENTIFIER
- OPERATION_IDENTIFIER

In addition, objects of this class inherit the properties of the superclass of this class.

## Methods

This class has the following methods:

- IDLitCommand::AddItem
- IDLitCommand::Cleanup
- IDLitCommand::GetItem
- IDLitCommand::GetProperty
- IDLitCommand::GetSize

- IDLitCommand::Init
- IDLitCommand::SetProperty

In addition, this class inherits the methods of its superclass.

## Examples

See "Creating a New Generalized Operation" in Chapter 7 of the *iTool Developer's Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

# IDLitCommand Properties

IDLitCommand objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLitCommand::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be set via IDLitCommand::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLitCommand::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## TARGET_IDENTIFIER

The iTool identifier of the *target* object for this command. This is the item on which the operation associated with the command will execute.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## OPERATION_IDENTIFIER

The iTool identifier for the *operation* associated with this command. When an undo-redo operation takes place, the command object is passed to this operation.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLitCommand::AddItem

The IDLitCommand::AddItem function method adds the specified data item to the data dictionary associated with this object.

**Note**

If a data item with the specified identifying string is already in the data dictionary, the new value is not added unless the OVERWRITE keyword is set, in which case the old value is discarded.

## Syntax

*Result* = *Obj* -> [IDLitCommand::]AddItem(*StrItem, Item*[, /OVERWRITE])

## Return Value

Returns 1 if the item was successfully added to the data dictionary, or 0 if the new value was not added.

## Arguments

### StrItem

A scalar string used to identify the data specified by the *Item* argument in the data dictionary. This string is treated in a case-insensitive manner.

### Item

A data item of any IDL data type.

## Keywords

### OVERWRITE

Normally, if an item already exists in the data dictionary of an IDLitCommand object, it is not overwritten. If this keyword is set, the original value will be overwritten.

**Note**

If the item being replaced uses dynamic memory (that is, if it is a pointer or object reference), the memory must be released by calling PTR_FREE or OBJ_DESTROY before overwriting the value.

## Version History

Introduced: 6.0

# IDLitCommand::Cleanup

The IDLitCommand::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitCommand::]Cleanup() *(In a subclass' Init method only.)*

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitCommand::GetItem

The IDLitCommand::GetItem function method retrieves the specified item from the data dictionary associated with this object.

## Syntax

*Result* = *Obj* -> [IDLitCommand::]GetItem(*StrItem*, *Item*)

## Return Value

Returns 1 if the *Item* is retrieved successfully, or 0 if *Item* is not found in the data dictionary.

## Arguments

### StrItem

A scalar string used to identify the data to be retrieved from the data dictionary. This string is treated in a case-insensitive manner.

### Item

A named IDL variable that will contain the IDLitData object retrieved from the data dictionary.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitCommand::GetProperty

The IDLitCommand::GetProperty procedure method retrieves the value of a property or group of properties of a command object.

## Syntax

*Obj* -> [IDLitCommand::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLitCommand Properties” on page 2727 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s super-class.

## Version History

Introduced: 6.0

# IDLitCommand::GetSize

The IDLitCommand::GetSize function method returns an approximate value for the amount of memory being used by the items in the data dictionary associated with this object.

## Syntax

*Result* = *Obj* -> [IDLitCommand::]GetSize([, /KILOBYTES])

## Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

## Arguments

None

## Keywords

### KILOBYTES

Set this keyword to return the number of kilobytes of memory being used by the data dictionary. By default, this function returns the number of bytes of memory being used.

## Version History

Introduced: 6.0

# IDLitCommand::Init

The IDLitCommand::Init function method initializes the object and allows specification of items associated with it.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitCommand' [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLitCommand::]Init([*PROPERTY=value*])
*(In a subclass' Init method only.)*

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLitCommand Properties" on page 2727 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object (IDLitComponent).

## Version History

Introduced: 6.0

# IDLitCommand::SetProperty

The IDLitCommand::SetProperty procedure method sets the value of a property or group of properties for the command object.

## Syntax

*Obj* -> [IDLitCommand::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLitCommand Properties” on page 2727 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitCommandSet

The IDLitCommandSet class stores a collection of IDLitCommand objects, allowing a group of commands to be managed as a single item. Command sets are useful as containers for IDLitCommand objects generated by the application of an iTool operation to multiple target items; the generated command set objects are used to provide undo/redo functionality to the iTool system.

This class is written in the IDL language. Its source code can be found in the file `idlitcommandset__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

TrackBall

IDLitCommand

## Creation

See "IDLitCommandSet::Init" on page 2742.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- IDLitCommandSet::Cleanup
- IDLitCommandSet::GetSize
- IDLitCommandSet::Init

In addition, this class inherits the methods of its superclasses.

## Examples

See "Creating a New Generalized Operation" in Chapter 7 of the *iTool Developer's Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

# IDLitCommandSet Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

# IDLitCommandSet::Cleanup

The IDLitCommandSet::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, Obj

or

*Obj* -> [IDLitCommandSet::]Cleanup() (*In a subclass' Init method only.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitCommandSet::GetSize

The IDLitCommandSet::GetSize function method returns an approximate value for the amount of memory being used by the items contained by this command set. When called, the method will call the GetSize method on all of the command objects that it contains and generate a sum of the values.

## Syntax

*Result* = *Obj* -> [IDLitCommand::]GetSize([/KILOBYTES])

## Return Value

Returns the number of bytes of memory used by the data dictionary associated with this object. The returned value is an approximation.

## Arguments

None

## Keywords

### KILOBYTES

Set this keyword to return the number of kilobytes of memory being used. By default, this function returns the number of bytes of memory being used.

## Version History

Introduced: 6.0

# IDLitCommandSet::Init

The IDLitCommandSet::Init function method initializes the object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitCommandSet')

or

*Result* = *Obj* -> [IDLitCommandSet::]Init() (*In a subclass' Init method only.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

All keywords are passed to the superclass of this object (IDLitCommand).

## Version History

Introduced: 6.0

# IDLitComponent

The IDLitComponent class is the base component from which all iTool components should subclass. The IDLitComponent class provides support for property descriptors and property registration, and defines properties that are common to all iTool component objects.

**Note**

This class is now a superclass of all the atomic graphical (IDLgr*) object classes.

## Superclasses

This class has no superclasses.

## Creation

See "IDLitComponent::Init" on page 2755.

## Properties

Objects of this class have the following properties. See "IDLitComponent Properties" on page 2745 for details on individual properties.

- DESCRIPTION
- HELP
- ICON
- IDENTIFIER
- NAME
- UVALUE

## Methods

This class has the following methods:

- IDLitComponent::Cleanup
- IDLitComponent::EditUserDefProperty
- IDLitComponent::GetFullIdentifier

- IDLitComponent::GetProperty
- IDLitComponent::GetPropertyAttribute
- IDLitComponent::GetPropertyByIdentifier
- IDLitComponent::Init
- IDLitComponent::QueryProperty
- IDLitComponent::RegisterProperty
- IDLitComponent::SetProperty
- IDLitComponent::SetPropertyAttribute
- IDLitComponent::SetPropertyByIdentifier

## Version History

Introduced: 6.0

# IDLitComponent Properties

IDLitComponent objects have the following properties. Properties with the word "Yes" in the "Get" column of the property table can be retrieved via IDLitComponent::GetProperty. Properties with the word "Yes" in the "Init" column of the property table can be set via IDLitComponent::Init. Properties with the word "Yes" in the "Set" column in the property table can be set via IDLitComponent::SetProperty.

**Note**

For a discussion of the property description tables shown below, see "About Object Property Descriptions" on page 2505.

## DESCRIPTION

A string giving the full name or description of this object.

| | | | |
|---|---|---|---|
| **Property Type** | STRING | | |
| **Name String** | Description | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ICON

A string specifying the name of an icon to be associated with this object. Typically, this property is the name of a bitmap file used when displaying this object in a tree view. See "System Resources" in Chapter 2 of the *iTool Developer's Guide* manual for details.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## HELP

A scalar string representing the help topic associated with this object. If this property is not set, or is set to a null string, then the object class name will be used as the default help topic.

| | |
|---|---|
| **Property Type** | String |

| **Name String** | *not displayed* | | |
|---|---|---|---|
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## IDENTIFIER

A string containing the *object identifier* for this object. If this property is not specified, then the NAME property is used as the identifier. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for details about how identifiers are named.

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## NAME

A string giving the human-readable name of this object.

| **Property Type** | STRING | | |
|---|---|---|---|
| **Name String** | Name | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PRIVATE

A boolean value that indicates whether the object should be marked as private. Objects marked private (and all of their children) are not displayed in the graphical iTool browser windows.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## UVALUE

A value of any type containing any information you wish. If you set this user value equal to a pointer or object reference that does not belong to a container, you should

explicitly destroy that pointer or object reference when destroying the object of which this property is a user value.

| | | | |
|---|---|---|---|
| **Property Type** | User Defined | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLitComponent::Cleanup

The IDLitComponent::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitComponent::]Cleanup (*only in subclass' Cleanup method*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitComponent::EditUserDefProperty

The IDLitComponent::EditUserDefProperty function method defines the interface that is displayed when a user selects the “Edit” button on a user-defined property in the property sheet interface. Typically, this method will display an interactive dialog that allows the user to change the value of the property.

**Note**

An iTool object class that includes a user-defined property *must* implement this method if the property is displayed in a property sheet — that is, if the property is registered and not hidden. If an iTool object class has no user-defined properties that are displayed in a property sheet, there is no need to supply an EditUserDefProperty method.

See “User Defined Property Types” in Chapter 4 of the *iTool Developer’s Guide* manual for a discussion of how the property sheet interface displays user-defined properties.

## Syntax

*Result* = *Obj* -> [IDLitComponent::] EditUserDefProperty(*iTool*, *PropertyIdentifier*)

## Return Value

Returns a 1 if the property value was changed, or a 0 if the property value was not changed.

**Note**

If the return value is 1, the property sheet interface automatically updates the displayed property value using the value of the property’s USERDEF attribute. If the return value is 0, no update takes place.

## Arguments

### iTool

An object reference to the current iTool object.

### PropertyIdentifier

A string containing the property identifier of the user-defined property.

**Tip**

Since there can only be one EditUserDefProperty method for each class, you can use the *PropertyIdentifier* argument to determine which user-defined property is being edited.

## Keywords

None

## Example

The following is the EditUserDefProperty method of the IDLitOpConvolution operation class. Selecting and editing the Kernel property of this operation displays a dialog that allows the user to edit a convolution kernel.

```
FUNCTION IDLitopConvolution::EditUserDefProperty, oTool, $
   identifier

CASE identifier OF

   'KERNEL': RETURN, oTool -> DoUIService('ConvolKernel', self)

   ELSE:

ENDCASE

RETURN, 0

END
```

This method simply checks the property identifier to determine whether it matches the string `'KERNEL'`. If it does, it returns the value returned by the DoUIService method; otherwise it returns zero. In this case, the DoUIService method actually handles the modification of the property value. See “User Defined Property Types” in Chapter 4 of the *iTool Developer’s Guide* manual for additional discussion.

## Version History

Introduced: 6.0

# IDLitComponent::GetFullIdentifier

The IDLitComponent::GetFullIdentifier function method navigates the iTool object container hierarchy of the object on which it is called and retrieves the fully-qualified object identifier. The full identifier is constructed by recursively retrieving the parent object reference and prepending this to the identifier, separated by / characters. The parent must inherit from the IDLitContainer class. The full identifier string has the following form:

```
/TOPID/GRANDPARENTID/PARENTID/OBJID
```

If the *Objref* argument is specified, the function returns the object identifier path relative to the specified object.

See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for additional discussion of object identifiers.

## Syntax

*Result* = *Obj* -> [IDLitComponent::]GetFullIdentifier([*Objref*])

## Return Value

Returns a string containing the object identifier.

## Arguments

### Objref

An object reference to an iTool component object. If this argument is specified, the returned value is an relative object identifier, beginning with Objref. If this argument is not specified, the returned value is a fully-qualified object identifier.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitComponent::GetProperty

The IDLitComponent::GetProperty procedure method retrieves the value of an IDLitComponent property or properties.

## Syntax

*Obj* -> [IDLitComponent::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLitComponent Properties” on page 2745 that contains that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitComponent::GetPropertyAttribute

The IDLitComponent::GetPropertyAttribute procedure method retrieves property attribute values for a registered property.

## Syntax

*Obj* -> [IDLitComponent::]GetPropertyAttribute, *PropertyIdentifier* [, TYPE=*variable*]

## Arguments

### PropertyIdentifier

A string containing the property identifier of the registered property.

## Keywords

Any keywords to the RegisterProperty method followed by the word “Get” can be retrieved. In addition, the following keyword is available:

### TYPE

Set this argument to a named variable that returns the TYPE code as an integer, as specified under the *Type* argument to IDLitComponent::RegisterProperty.

## Version History

Introduced: 6.0

# IDLitComponent::GetPropertyByIdentifier

The IDLitComponent::GetPropertyByIdentifier function method retrieves the value of an IDLitComponent property.

**Tip**

The IDLitComponent::GetPropertyByIdentifier method is similar to the IDLitComponent::GetProperty method, but is useful for cases where the *property identifier* is defined at runtime.

## Syntax

*Result* = *Obj* -> [IDLitComponent::]GetPropertyByIdentifier(*PropertyIdentifier*, *Value*)

## Return Value

Returns 1 if the property value is defined, or 0 if the property value is undefined.

## Arguments

### PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the GetProperty method of the component.

### Value

A named variable that will contain the value of the property. If the property value is currently undefined, then the contents of the variable specified by *Value* will not be modified.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitComponent::Init

The IDLitComponent::Init function method initializes the IDLitComponent object, and should be called by the Init method of a subclass.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitComponent'[, *PROPERTY=value*] )

or

*Result* = *Obj* -> [IDLitComponent::]Init([, *PROPERTY=value*])
(*Only in a subclass' Init method.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLitComponent Properties" on page 2745 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitComponent::QueryProperty

The IDLitComponent::QueryProperty function method checks whether a property identifier is registered, or retrieves a list of all registered properties.

## Syntax

*Result* = *Obj* -> [IDLitComponent::]QueryProperty([*PropertyIdentifier*])

## Return Value

Returns a 1 if *PropertyIdentifier* is a scalar string that corresponds to a valid registered property, or a 0 otherwise. If *PropertyIdentifier* is an array, the result is an array of 1s and 0s.

If *PropertyIdentifier* is not specified, *Result* is a string array containing the identifiers of all registered properties.

## Arguments

### PropertyIdentifier

A scalar string or string array containing property identifiers.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitComponent::RegisterProperty

The IDLitComponent::RegisterProperty procedure method registers a property as belonging to the component. Only registered properties are displayed in the graphical property sheet interface for the object.

# Syntax

*Obj* -> [IDLitComponent::]RegisterProperty, *PropertyIdentifier*[, *Type*] [, /BOOLEAN] [, /COLOR] [, DESCRIPTION=*string*] [, ENUMLIST=*stringvector*] [, /FLOAT] [, /HIDE] [, /INTEGER] [, /LINESTYLE] [, NAME=*string*] [, /SENSITIVE] [, /STRING] [, /SYMBOL] [, /THICKNESS] [, /UNDEFINED] [, USERDEF=*string*] [, VALID_RANGE=*vector*]

# Arguments

## PropertyIdentifier

A scalar string containing the property identifier. GetProperty and SetProperty methods accept this string as a keyword.

## Type

An optional integer argument representing the property type. Values recognized by Property Sheets are:

- 0 = USERDEF
- 1 = BOOLEAN
- 2 = INTEGER
- 3 = FLOAT
- 4 = STRING
- 5 = COLOR
- 6 = LINESTYLE
- 7 = SYMBOL
- 8 = THICKNESS
- 9 = ENUMLIST

If *Type* is not supplied, then one of the type keywords must be set instead.

# Keywords

Some of the following keywords correspond to *attributes* of the property being registered. Keywords followed by the word “Get” indicate attributes that can be retrieved by the IDLitComponent::GetPropertyAttribute method. Keywords followed by the word “Set” indicate attributes that can be set by the IDLitComponent::SetPropertyAttribute method.

Some of the following keywords correspond to iTool property data types, which can also be specified via the *Type* argument. Note that if both the *Type* argument and one of the corresponding keywords are set, the keyword value will be honored.

## BOOLEAN

Set this keyword to indicate that the property type is BOOLEAN. Properties of type BOOLEAN must accept an integer value of either 0 (“False”) or 1 (“True”). Setting this keyword is equivalent to setting the TYPE argument equal to 1.

## COLOR

Set this keyword to indicate that the property type is COLOR. Properties of type COLOR must accept a three-element integer array containing an RGB triplet. Setting this keyword is equivalent to setting the TYPE argument equal to 5.

## DESCRIPTION (Get, Set)

Set this keyword to a string containing the full name or description of this property. The DESCRIPTION is displayed in the graphical property sheet interface.

**Note**

Do not confuse the DESCRIPTION *property attribute* with the DESCRIPTION *property.*

## ENUMLIST (Get, Set)

Set this keyword equal to an array of strings to be displayed in the dropdown menu displayed by a property of type ENUMLIST. The default is a scalar null string. Properties of type ENUMLIST report their value as an integer between 0 and *n*-1, where *n* is the number of elements in the enumerated list. Setting this keyword implies that the TYPE argument is equal to 9.

## FLOAT

Set this keyword to indicate that the property type is FLOAT. Properties of type FLOAT must accept a scalar double-precision floating-point value. Setting this keyword is equivalent to setting the TYPE argument equal to 3.

## HIDE (Get, Set)

Set this keyword to hide the given property when displaying the graphical property sheet interface. By default, all registered properties are displayed.

## INTEGER

Set this keyword to indicate that the property type is INTEGER. Properties of type INTEGER must accept a scalar integer value. Setting this keyword is equivalent to setting the TYPE argument equal to 2.

## LINESTYLE

Set this keyword to indicate that the property type is LINESTYLE. Properties of type LINESTYLE must accept an integer specifying a pre-defined linestyle, as described under the LINESTYLE property of the IDLgrPolyline class. Setting this keyword is equivalent to setting the TYPE argument equal to 6.

## NAME (Get, Set)

Set this keyword to a string giving the human-readable name for the property. The NAME string will be used when displaying the graphical property sheet interface. If NAME is not set, the value of the *PropertyIdentifier* argument is used.

**Note**

Do not confuse the NAME *property attribute* with the NAME *property.*

## SENSITIVE (Get, Set)

Set this keyword to zero to make the given property insensitive in the graphical property sheet interface. By default, registered properties are sensitive.

## STRING

Set this keyword to indicate that the property type is STRING. Properties of type STRING must accept a scalar string of any length. Setting this keyword is equivalent to setting the TYPE argument equal to 4.

## SYMBOL

Set this keyword to indicate that the property type is SYMBOL. Properties of type SYMBOL must accept an integer specifying one of the pre-defined symbol types described under IDLgrSymbol::Init. Setting this keyword is equivalent to setting the TYPE argument equal to 7.

## THICKNESS

Set this keyword to indicate that the property type is THICKNESS. Properties of type THICKNESS must accept an integer between 1 and 10 specifying the line thickness in points. Setting this keyword is equivalent to setting the TYPE argument equal to 8.

## UNDEFINED (Get, Set)

Set this keyword to indicate that the property should appear as a blank cell when displayed in the graphical property sheet interface. This is useful in situations where properties of multiple objects are displayed in the property sheet (either because multiple objects are selected, or because the objects have been grouped).

**Note**

It is the iTool developer's responsibility to set this property attribute back to zero. Use the SET_DEFINED field of the WIDGET_PROPERTYSHEET event structure to determine when to set the UNDEFINED attribute back to zero.

## USERDEF (Get, Set)

Set this keyword to a string that represents a user-defined property. Properties of type USERDEF can accept and return variables of any type. When the actual property value changes, it is assumed that the string value of the USERDEF attribute will also be modified to reflect the new property value. Setting this keyword implies that the TYPE argument is equal to 0.

## VALID_RANGE (Get, Set)

For INTEGER or FLOAT types, set this keyword to a two- or three-element vector specifying the [*minimum*, *maximum*] or [*minimum*, *maximum*, *increment*] for valid values of the property.

If no *increment* is specified, the property sheet will display an editable text field allowing the user to enter a numerical value. If *increment* is specified, values in the property sheet can only be changed by adjusting a slider, and allowed values are limited to multiples of the increment value plus the minimum value. If *increment* is 0, any value between the minimum and maximum can be selected via the slider.

If this attribute is not set, or is explicitly set equal to zero, the property sheet will use the minimum and maximum values expressible by the data type and an *increment* of 0.

## Version History

Introduced: 6.0

# IDLitComponent::SetProperty

The IDLitComponent::SetProperty procedure method sets the value of an IDLitComponent property or properties.

## Syntax

*Obj* -> [IDLitComponent::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLitComponent Properties” on page 2745 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitComponent::SetPropertyAttribute

The IDLitComponent::SetPropertyAttribute procedure method sets one or more property attributes for a registered property.

## Syntax

*Obj* -> [IDLitComponent::]SetPropertyAttribute , *PropertyIdentifier*

## Arguments

### PropertyIdentifier

A string containing the property identifier of the registered property.

## Keywords

Any keywords to the IDLitComponent::RegisterProperty method followed by the word “Set” can be set.

## Version History

Introduced: 6.0

# IDLitComponent::SetPropertyByIdentifier

The IDLitComponent::SetPropertyByIdentifier procedure method sets the value of an IDLitComponent property.

**Tip**

The IDLitComponent::SetPropertyByIdentifier method is similar to the IDLitComponent::SetProperty method, but is useful for cases where the *PropertyIdentifier* is defined at runtime, and avoids the overhead of creating an _EXTRA structure to pass to SetProperty.

## Syntax

*Obj* -> [IDLitComponent::]SetPropertyByIdentifier, *PropertyIdentifier*, *Value*

## Arguments

### PropertyIdentifier

A string containing the property identifier of the property. *PropertyIdentifier* does not need to be a registered property, but must be a valid keyword name for the SetProperty method of the component.

### Value

The new value for the property.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitContainer

The IDLitContainer class is a specialization of the IDL_Container class designed to manage collections of IDLitComponent objects and provide methods to work with the iTools *identifier* system. IDLitContainer object methods allow you to add, retrieve, and remove values from a IDLitContainer-based hierarchy using either object references or iTool identifiers.

This class is written in the IDL language. Its source code can be found in the file `idlitcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDL_Container

IDLitComponent

## Creation

See "IDLitContainer::Init" on page 2775.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- IDLitContainer::Add
- IDLitContainer::AddByIdentifier
- IDLitContainer::Cleanup
- IDLitContainer::Get
- IDLitContainer::GetByIdentifier
- IDLitContainer::Init

- IDLitContainer::Remove
- IDLitContainer::RemoveByIdentifier

In addition, this class inherits the methods of its superclasses.

## Version History

Introduced: 6.0

# IDLitContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

# IDLitContainer::Add

The IDLitContainer::Add procedure method adds items to the container object.

## Syntax

*Obj* -> [IDLitContainer::]Add, *Components*[, /NO_NOTIFY]

## Arguments

### Components

An object reference (or array of object references) to the IDLitComponent object or objects to be added to the container. When this method is called, the IDENTIFIER properties of objects specified by *Components* are validated, verifying that no items in the container have the same value. If an object with the same identifier already exists in the container, a unique identifier is created by appending a number to the original value.

## Keywords

### NO_NOTIFY

Normally, when an item is added to a container object that inherits from both the IDLitContainer class and the IDLitIMessaging class, an ADDITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

## Version History

Introduced: 6.0

# IDLitContainer::AddByIdentifier

The IDLitContainer::AddByIdentifier procedure method adds an object to the container hierarchy in the position specified by the *Identifier* argument.

## Syntax

*Obj* -> [IDLitContainer::]AddByIdentifier, *Identifier*, *Item*

## Arguments

### Identifier

An object identifier specifying the location in the container hierarchy where Item should be added. *Identifier* can be either a fully-qualified object identifier (beginning with a "/" character) or a relative to the container on which this method is called. If *Identifier* is a null string (`''`), Item is added to the root of the container object.

See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object identifier strings.

### Item

An object reference to the iTool component object being added to the container.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitContainer::Cleanup

The IDLitContainer::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitContainer::]Cleanup (*Only in subclass' Cleanup method.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitContainer::Get

The IDLitContainer::Get function method retrieves items from the container.

## Syntax

*Result* = *Obj* -> [IDLitContainer::]Get([, /ALL] [, COUNT=*variable*] [, ISA=*string* or *array of strings*] [, POSITION=*index* or *array of indices*] [, /SKIP_PRIVATE])

## Return Value

Returns an object reference or array of object references to the iTool components stored in the container. Unless either the ALL keyword or the POSITION keyword is specified, the first object in the container is returned. If no objects are found in the container, the return value is -1.

## Arguments

None

## Keywords

### ALL

Set this keyword to return an array of object references to all of the objects in the container.

### COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

### ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

**Note**

This keyword is ignored if the ALL keyword is not provided.

### POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

### SKIP_PRIVATE

Set this keyword to ignore any components for which the PRIVATE property is set to true. This keyword is ignored unless the ALL keyword is also set.

## Version History

Introduced: 6.0

# IDLitContainer::GetByIdentifier

The IDLitContainer::GetByIdentifier function method retrieves an object from a container hierarchy using the specified identifier to locate the object.

## Syntax

*Result* = *Obj* -> [IDLitContainer::]GetByIdentifier(*Identifier*)

## Return Value

Returns an object reference to the object that was requested from the hierarchy, or a null object reference if no object was located.

## Arguments

### Identifier

The object identifier of the object that should be retrieved from the container hierarchy. *Identifier* can be either a fully-qualified object identifier (beginning with a "/" character) or a relative to the container on which this method is called.

See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object identifier strings.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitContainer::Init

The IDLitContainer::Init function method initializes the object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitContainer')

or

*Result* = *Obj* -> [IDLitContainer::]Init() (*Only in subclass' Init method.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitContainer::Remove

The IDLitContainer::Remove procedure method removes items from the container.

## Syntax

*Obj* -> [IDLitContainer::]Remove, *Components*[, /NO_NOTIFY]

## Arguments

### Components

An object reference (or array of object references) to the objects to be removed from the container.

## Keywords

### NO_NOTIFY

Normally, when an item is removed from a container object that inherits from both the IDLitContainer class and the IDLitIMessaging class, a REMOVEITEMS notification message is broadcast to all iTool components registered as monitoring this container. If this keyword is set, no message is sent.

## Version History

Introduced: 6.0

# IDLitContainer::RemoveByIdentifier

The IDLitContainer::RemoveByIdentifier function method removes an object from a container hierarchy using the specified identifier to locate the object.

## Syntax

*Result* = *Obj* -> [IDLitContainer::]RemoveByIdentifier(*Identifier*)

## Return Value

Returns an object reference to the object that was removed from the hierarchy, or a null object reference if no object was removed.

## Arguments

### Identifier

The object identifier of the object that should be removed from the container hierarchy. The *Identifier* argument can be either a fully-qualified object identifier (beginning with a "/" character) or a relative to the container on which this method is called.

See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object identifier strings.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitData

The IDLitData class provides a generic data storage object that can hold data items of any IDL data type. The IDLitData class provides typing and data change notification functionality, and when coupled with the IDLitDataContainer object forms the base element for the construction of composite data types.

The IDLitData class implements the iTools *notifier interface*, which provides a mechanism by which observers of a data item can be alerted when the state of the information contained in the data object changes.

This class is written in the IDL language. Its source code can be found in the file `idlitdata__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitComponent

## Creation

See “IDLitData::Init” on page 2789.

## Properties

Objects of this class have the following properties. See “IDLitData Properties” on page 2780 for details on individual properties.

- HIDE
- NO_COPY
- READ_ONLY
- TYPE

In addition, objects of this class inherit the properties of the superclass.

## Methods

This class has the following methods:

- IDLitData::AddDataObserver
- IDLitData::Cleanup
- IDLitData::Copy
- IDLitData::GetByType
- IDLitData::GetData
- IDLitData::GetProperty
- IDLitData::GetSize
- IDLitData::Init
- IDLitData::NotifyDataChange
- IDLitData::NotifyDataComplete
- IDLitData::RemoveDataObserver
- IDLitData::SetData
- IDLitData::SetProperty

In addition, this class inherits the methods of its superclasses.

## Examples

See Chapter 3, “Data Management” in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

# IDLitData Properties

IDLitData objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLitData::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be set via IDLitData::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLitData::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## HIDE

A Boolean value that controls the visibility of the data with respect to queries performed by the IDLitDataContainer methods GetData, SetData and GetIdentifiers. If the HIDE property has a True value, the data object is not found by these methods and the methods behave as if the data object did not exist.

| | | | |
|---|---|---|---|
| **Property Type** | BOOLEAN | | |
| **Name String** | HIDE | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## NO_COPY

If an initial value of the data is provided, this property will cause the movement of the data into the object without creating an additional copy, leaving the IDL variable named by the Data argument undefined.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## READ_ONLY

A Boolean value that controls the ability to modify the data with the SetData method. If the READ_ONLY property has a True value, an attempt to use SetData on the object fails. IDL prints an informational message in this case.

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | READ_ONLY | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TYPE

A scalar string containing the type of the data object. The default value of this property is NULL (`''`) and cannot be changed after the class is instantiated. Subclasses of this class set the value of this property to a value that reflects the type of data that the subclass is implementing.

| **Property Type** | STRING | | |
|---|---|---|---|
| **Name String** | TYPE | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

# IDLitData::AddDataObserver

The IDLitData::AddDataObserver procedure method specifies an object (the *Observer*) that will be notified when the contents of the data object are changed.

The object specified as the *Observer* must implement three methods that form the data observer interface:

- OnDataChange
- OnDataComplete
- OnDataDelete

The OnDataChange method is called when the contents of a data object are changed, and the OnDataComplete method is called when the change messages are completed. This two-part notification process is used to allow observers of data to transact the change event and minimize the required system updates (such as graphic redrawing). The OnDataDelete method is called when the data item is deleted.

## Syntax

*Obj* -> [IDLitData::]AddDataObserver, *Observer*

## Arguments

### Observer

An object reference to an iTool component object that implements the data observer interface methods. When the contained data value changes, the *Observer* is notified of this change.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitData::Cleanup

The IDLitData::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method removes all data stored in the IDLitData object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitData::]Cleanup (*only in subclass' Cleanup method*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitData::Copy

The IDLitData::Copy function method returns an exact copy of the data object and its contents, including registered property values.

The following values are *not* copied:

- Values of unregistered properties.
- Values of properties registered after the data object is created.
- Property attribute values.

**Note**

If an object has been added to the data object, only the object reference to the added object is copied.

## Syntax

*Result* = *Obj* -> [IDLitData::]Copy()

## Return Value

Returns a copy of the object on which it is called. If the copy operation fails, a null object is returned.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitData::GetByType

The IDLitData::GetByType function method returns all contained objects of the specified iTool data type.

## Syntax

*Result* = *Obj* -> [IDLitData::]GetByType(*Type*[, COUNT=*variable*])

## Return Value

Returns an object array containing references to the contained data objects that are of the iTool data type specified by *Type*. If no objects matching *Type* exist, a null object reference is returned.

## Arguments

### Type

A string containing the iTool data type to search for in the data hierarchy rooted by this data container.

## Keywords

### COUNT

Set this keyword equal to a named variable that will contain the number of valid objects returned by this method.

## Version History

Introduced: 6.0

# IDLitData::GetData

The IDLitData::GetData function method retrieves the data stored in the object.

## Syntax

*Result* = *Obj* -> [IDLitData::]GetData(*Data*[, *Identifier*] [, NAN=*variable*] [, /NO_COPY])

## Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

## Arguments

### Data

A named variable that will contain the data retrieved from the data object. If the GetData method fails, the variable is not modified.

### Identifier

A string argument that is not used by this method, but is accepted for parameter compatibility with the IDLitDataContainer::GetData method. If a value for this argument is supplied, the method does not retrieve any data and returns the value 0.

## Keywords

### NAN

Set this keyword to a named variable that will contain 1 if *Data* contains any non-finite values (either NaN or Infinity), or 0 otherwise.

### NO_COPY

Set this keyword to move the data from the data object to the variable specified by the *Data* argument, leaving the data value of the data object undefined.

## Version History

Introduced: 6.0

# IDLitData::GetProperty

The IDLitData::GetProperty procedure method retrieves the value of an IDLitData property, and should be called by the GetProperty method of any subclass of this class.

## Syntax

*Obj* -> [IDLitData::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLitData Properties” on page 2780 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitData::GetSize

The IDLitData::GetSize function method returns an approximate value for the amount of memory being used by the data object.

## Syntax

*Result* = *Obj* -> [IDLitData::]GetSize()

## Return Value

Returns the number of bytes of memory used by the data object. The returned value is an approximation.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitData::Init

The IDLitData::Init function method initializes the IDLitData object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitData'[, *Data*] [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLitData::]Init([*Data*] [, *PROPERTY=value*])
(*Only in subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Data

An IDL variable of any type that is stored in the data object.

## Keywords

Any property listed under “IDLitData Properties” on page 2780 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitData::NotifyDataChange

The IDLitData::NotifyDataChange procedure method is called when a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataComplete method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the OnDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' OnDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

**Note**

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

## Syntax

*Obj* -> [IDLitData::]NotifyDataChange

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitData::NotifyDataComplete

The IDLitData::NotifyDataComplete procedure method is called after a data object has been changed; it is part of the notification process that allows data updates to be reflected by visualizations that use the data. It works in conjunction with the NotifyDataChange method to provide a two-pass change notification system that minimizes the number of operations performed when a data object changes.

When NotifyDataChange is called, the OnDataChange methods of all observers of the data object (usually visualizations) are automatically called. This causes the observers to perform any necessary updates *without committing those updates*. When the NotifyDataComplete method is called, the observers' OnDataComplete methods are called to commit the updates. This two-pass system allows visualizations to be notified that the data has changed without forcing an immediate redraw of the iTool window; when the NotifyDataComplete method is called, all visualizations can be redrawn at once.

Every call to the NotifyDataChange method must have an accompanying NotifyDataComplete call; without the call to NotifyDataComplete, no updates will take place.

**Note**

If the data object is being changed by an operation based on the IDLitDataOperation class, the call to NotifyDataChange is handled automatically. The only time you will need to call this method directly is if the operation that modifies the data is based on the more generic IDLitOperation class.

## Syntax

*Obj* -> [IDLitData::]NotifyDataComplete

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitData::RemoveDataObserver

The IDLitData::RemoveDataObserver method unregisters an object that has been registered as an *observer* of this data object. After this method is called, the Observer will no longer be notified when the contents of the data object change. If the specified *Observer* doesn't exist, this method will return quietly.

## Syntax

*Obj* -> [IDLitData::]RemoveDataObserver, *Observer*

## Arguments

### Observer

An object reference to an iTool component object that was previously registered as an observer of this data object.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitData::SetData

The IDLitData::SetData function method copies the data from an IDL variable or expression into the data object, and notifies all its observers that the data has changed.

## Syntax

*Result* = *Obj* -> [IDLitData::]SetData(*Data*[, *Identifier*] [, /NO_COPY] [, /NULL])

## Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

## Arguments

### Data

An IDL variable or expression whose value is copied into the data object.

### Identifier

A string argument that is not used by this method. It is accepted by this method only for parameter compatibility with IDLitDataContainer::SetData. If a value for this argument is supplied, the method does not retrieve any data and returns the value 0.

## Keywords

### NO_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

### NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored.

## Version History

Introduced: 6.0

# IDLitData::SetProperty

The IDLitData::SetProperty procedure method sets the value of an IDLitData property, and should be called by the SetProperty method of any subclass of this class.

## Syntax

*Obj* -> [IDLitData::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLitData Properties” on page 2780 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitDataContainer

The IDLitDataContainer class is used to store collections of IDLitData and IDLitDataContainer objects to form hierarchical data structures. Objects can be added to and removed from an IDLitDataContainer at any time, allowing for the dynamic creation of composite data types.

Objects stored in an IDLitDataContainer hierarchy are referenced using iTool *object identifiers*. Object identifiers are simple scalar strings assigned to the IDENTIFIER property of an object when it is created. For a complete discussion of object identifiers and their role in the iTool system, see "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitdatacontainer__define.pro` in the `lib/itool/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitContainer

IDLitData

## Creation

See "IDLitDataContainer::Init" on page 2803.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- IDLitDataContainer::Cleanup
- IDLitDataContainer::GetData
- IDLitDataContainer::GetIdentifiers
- IDLitDataContainer::GetProperty
- IDLitDataContainer::Init

- IDLitDataContainer::SetData
- IDLitDataContainer::SetProperty

In addition, this class inherits the methods of its superclasses.

## Examples

See Chapter 3, “Data Management” in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

# IDLitDataContainer Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

# IDLitDataContainer::Cleanup

The IDLitDataContainer::Cleanup procedure method performs all cleanup operations on the object, and should be called by the Cleanup method of any subclass of this class. This method destroys all data objects stored in this container.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitDataContainer::]Cleanup (*only in subclass' Cleanup method*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitDataContainer::GetData

The IDLitDataContainer::GetData function method retrieves the data value contained in the data object specified by the *Identifier* argument.

## Syntax

*Result* = *Obj* -> [IDLitDataContainer::]GetData(*Data* [, *Identifier*] [, /NO_COPY])

## Return Value

Returns a 1 if the operation succeeds, and 0 if it fails.

## Arguments

### Data

A named variable that will contain the data value of the specified data object.

### Identifier

A string containing the relative object identifier path to the target data object for this method. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object identifier strings.

If *Identifier* is not set. or is set to a null string, the data contained in the data container itself is returned.

## Keywords

### NO_COPY

Set this keyword to move the data from the data container object to the variable specified by the *Data* argument, leaving the data value of the data object undefined.

## Version History

Introduced: 6.0

# IDLitDataContainer::GetIdentifiers

The IDLitDataContainer::GetIdentifiers function method retrieves the object identifiers for all data and data container objects contained in the data container object.

## Syntax

*Result* = *Obj* -> [IDLitDataContainer::]GetDataIdentifiers([*Pattern*] [, /LEAF])

## Return Value

Returns an array of strings containing the object identifiers for all data and data container objects contained by the data container object. If the container is empty, or if the Pattern argument is supplied and no object identifiers are matched, the function returns a string array containing one empty string ( [''] ).

## Arguments

### Pattern

A string specifying a search pattern to be used for filtering the returned object identifiers. Only object identifiers that match Pattern are returned. See STRMATCH for a description of the rules used when matching patterns.

## Keywords

### LEAF

Set this keyword to return only object identifiers whose final node is *not* a container object.

## Version History

Introduced: 6.0

# IDLitDataContainer::GetProperty

The IDLitDataContainer::GetProperty procedure method retrieves the value of an IDLitDataContainer property, and should be called by the GetProperty method of any subclass of this class.

## Syntax

*Obj* -> [IDLitDataContainer::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLitDataContainer Properties” on page 2798 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitDataContainer::Init

The IDLitDataContainer::Init function method initializes the IDLitDataContainer object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitDataContainer'[, *Data*] [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLitDataContainer::]Init([*Data*] [, *PROPERTY=value*])
(*Only in subclass' Init method.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Data

An IDL variable of any type or shape that is stored into the object at initialization.

## Keywords

Any property listed under “IDLitDataContainer Properties” on page 2798 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitDataContainer::SetData

The IDLitDataContainer::SetData function method stores data in the IDLitData object specified by *Identifier*. This method acts in exactly the same way as the IDLitData::SetData method.

## Syntax

*Result* = *Obj* -> [IDLitDataContainer::]SetData(*Data*, *Identifier*[, /NO_COPY] [, /NULL])

## Return Value

Returns a 1 if the operation succeeds, or 0 if it fails.

## Arguments

### Data

An IDL variable of any type that is copied into the specified data object.

### Identifier

A scalar string containing the object identifier of the IDLitData object in which the data specified by *Data* should be stored. This path must specify a valid IDLitData object, or the function fails. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object identifier strings.

## Keywords

### NO_COPY

Set this keyword to move the data into the specified IDLitData object without creating an additional copy. This leaves the original IDL variable named by the *Data* argument undefined.

### NULL

Set this keyword to remove any data stored in the IDLitData object, leaving it empty. If this keyword is set, the *Data* argument is ignored, but must still be present.

## Version History

Introduced: 6.0

# IDLitDataContainer::SetProperty

The IDLitDataContainer::SetProperty procedure method sets the value of an IDLitDataContainer property, and should be called by the SetProperty method of any subclass of this class.

## Syntax

*Obj* -> [IDLitDataContainer::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLitDataContainer Properties” on page 2798 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitDataOperation

The IDLitDataOperation class is a subclass of IDLitOperation that automates data access and automatically records information for the undo-redo system. By automating this functionality, the IDLitDataOperation class eliminates much of the work required to implement a standard subclass of the IDLitOperation class. See IDLitOperation for additional information on iTool operations.

**Note**

The IDLitDataOperation class is designed for use in operations that affect data values. If you are creating an operation that acts on items other than the data that underlies a visualization, you should base your operation class on the IDLitOperation class.

While the implementation of a standard subclass of an IDLitOperation class requires the developer to provide implementations of the DoAction, UndoOperation, and RedoOperation methods, the IDLitDataOperation class provides these methods automatically. The only method the developer of an IDLitDataOperation class is *required* to implement is the Execute method, which contains the logic for the specific operation being performed. Depending on the operation being performed, the developer of an IDLitDataOperation may also implement methods to reverse (or un-execute) the operation, display a user interface before performing the operation, get and set properties specific to the operation, and initialize the IDLitDataOperation object.

When an IDLitDataOperation is requested by a user, the following things occur:

1. As with any operation, execution commences when the DoAction method is called on this object. When called, the IDLitDataOperation retrieves the currently-selected items. If nothing is selected, the operation returns.
2. For each selected item, the data objects of the parameters registered as “operation targets” are retrieved.
3. The data objects are queried for iTool data types that match the types supported by the IDLitDataOperation.

For each data object that includes data of an iTool data type supported by the IDLitDataOperation, the following things occur:

1. The data from the data object is retrieved.
2. If the IDLitDataOperation does not have the REVERSIBLE_OPERATION property set, a copy of the data is created and placed into the undo-redo command set.
3. The Execute method is called, with the retrieved data as its argument.
4. If the Execute method succeeds and the IDLitDataOperation has the EXPENSIVE_OPERATION property set, a copy of the results is placed into the undo-redo command set.
5. The result of the IDLitDataOperation is placed in the data object. This action will cause all visualization items that use the data object to update when the operation is completed.

Once all selected data items have been processed, the undo-redo command set is placed into the system undo-redo buffer for later use.

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see Chapter 7, “Creating an Operation” in the *iTool Developer’s Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitdataoperation__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitOperation

## Creation

See “IDLitDataOperation::Init” on page 2818.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- IDLitDataOperation::Cleanup
- IDLitDataOperation::DoExecuteUI
- IDLitDataOperation::Execute
- IDLitDataOperation::GetProperty
- IDLitDataOperation::Init
- IDLitDataOperation::SetProperty
- IDLitDataOperation::UndoExecute

In addition, this class inherits the methods of its superclasses (if any).

## Examples

See "Creating a New Data-Centric Operation" in Appendix of the *iTool Developer's Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

## See Also

IDLitOperation

# IDLitDataOperation Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

# IDLitDataOperation::Cleanup

The IDLitDataOperation::Cleanup procedure method performs all cleanup on the object.

**Note**

An operation based on the IDLitDataOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* `->` [IDLitOperation::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitDataOperation::DoExecuteUI

The IDLitDataOperation::DoExecuteUI function method provides a way for the iTool developer to request user input before performing an operation. If the SHOW_EXECUTION_UI property is set, this method will be called before the operation's Execute method is called.

**Note**

Every operation based directly on the IDLitDataOperation class that requires user interaction before execution must implement its own DoExecuteUI method. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

The DoExecuteUI method itself can present any interface. In practice, most iTool DoExecuteUI methods use the IDLitTool::DoUIService method to display a user interface requesting user input. User interfaces and UI Services are discussed in Chapter 10, "iTool User Interface Architecture" in the *iTool Developer's Guide* manual.

**Warning**

If the DoExecuteUI method does not return success, the Execute method will not be called.

## Syntax

*Result* = *Obj* -> [IDLitDataOperation::]DoExecuteUI()

## Return Value

Returns a 1 if the displayed user interface code executed successfully, and the operation should be executed. If user interface code does not execute successfully, or if the user cancels the operation, this function returns a 0.

## Arguments

None

## Keywords

None

# Example

The following is an example of a DoExecuteUI method, taken from the iTools “Scale Factor” operation:

```
FUNCTION IDLitopScalefactor::DoExecuteUI

oTool = self -> GetTool()
IF (oTool EQ OBJ_NEW()) THEN RETURN, 0

RETURN, oTool -> DoUIService('ScaleFactor', self)

END
```

This implementation of the DoExecuteUI method does the following:

1. Retrieves an object reference to the current iTool using the GetTool method.
2. Checks to make sure the returned object reference is not a null object (which would be the case if the GetTool method failed).
3. Calls the `ScaleFactor` UI Service.

# Version History

Introduced: 6.0

# IDLitDataOperation::Execute

The IDLitDataOperation::Execute function method contains the execution logic for the operation. This method is called automatically when the iTool user requests an operation based on the IDLitDataOperation class.

**Note**

Every operation based directly on the IDLitDataOperation class must implement its own Execute method. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

When the iTool system executes an IDLitDataOperation, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the Execute method. This means that the Execute method itself does not need to "unpack" a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type `IDLARRAY2D`, the iTool system will include the selected two-dimensional array as the *Data* argument.

# Syntax

*Result* = *Obj* `->` [IDLitDataOperation::]Execute(*Data*)

# Return Value

The return value is 1 if the operation executed successfully, or 0 otherwise.

# Arguments

## Data

A single data item on which the operation should be performed. Note that *Data* is *not* an IDLitData object, but actual data.

# Keywords

None

## Version History

Introduced: 6.0

## See Also

IDLitDataOperation::UndoExecute

# IDLitDataOperation::GetProperty

The IDLitDataOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

**Note**

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

## Syntax

*Obj* -> [IDLitDataOperation::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under "IDLitDataOperation Properties" on page 2811 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Example

To retrieve the value of the REVERSIBLE_OPERATION property:

```
Obj -> IDLitDataOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

## Version History

Introduced: 6.0

# IDLitDataOperation::Init

The IDLitDataOperation::Init function method initializes the IDLitDataOperation object and sets properties that define the behavior the operation provides.

**Note**

An operation based on the IDLitDataOperation class *must* implement this method. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

**Note**

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitDataOperation' [, *PROPERTY=variable*] )

or

*Result* = *Obj* -> [IDLitDataOperation::]Init([, *PROPERTY=variable*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitDataOperation Properties” on page 2811 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal the appropriate property value.

## Version History

Introduced: 6.0

# IDLitDataOperation::SetProperty

The IDLitDataOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

**Note**

An operation based on the IDLitDataOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

## Syntax

*Obj* -> [IDLitDataOperation::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under "IDLitDataOperation Properties" on page 2811 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitDataOperation::UndoExecute

The IDLitDataOperation::UndoExecute function method is called when a user selects the Undo operation after executing an IDLitDataOperation that sets the value of the REVERSIBLE_OPERATION property to 1. (If the IDLitDataOperation does not set this property, the UndoExecute method is not called.) If implemented, this method generally applies the inverse of the operation performed by the Execute method.

**Note**

An operation based on the IDLitDataOperation class *must* implement this method if the operation sets the REVERSIBLE_OPERATION property. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

When the iTool system un-executes an IDLitDataOperation, it passes the *raw data* (of the appropriate iTools data type) from the selected objects to the UndoExecute method. This means that the UndoExecute method itself does not need to "unpack" a data object before performing the operations, allowing rapid and simple operation execution. For example, if the operation expects data of the iTools data type `IDLARRAY2D`, the iTool system will include the selected two-dimensional array as the *Data* argument.

## Syntax

*Result* = *Obj* `->` [IDLitDataOperation::]UndoExecute(*Data*)

## Return Value

The return value is 1 if the operation un-executed successfully, or 0 otherwise.

## Arguments

### Data

A single data item on which the operation should be performed. Note that *Data* is *not* an IDLitData object, but actual data.

## Keywords

None

## Version History

Introduced: 6.0

## See Also

IDLitDataOperation::Execute

# IDLitIMessaging

The IDLitIMessaging interface class provides a set of methods used to allow an object that implements the interface to send notification messages and to react appropriately when notification messages are received from other iTool component objects. This class also provides methods that allow the iTool developer to notify the iTool user of error conditions via graphical dialogs, to prompt the user for input, and to retrieve a reference to the current iTool object.

IDLitIMessaging objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

**Note**

In the iTools system, management of messages is handled by the IDLitVisualization class, of which the IDLitIMessaging class is a superclass. In practice, this means that if you need to override any methods of the IDLitIMessaging class, you will do so in the definition of your visualization class.

This class is written in the IDL language. Its source code can be found in the file `idlitimessaging__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

This class has no superclasses.

## Creation

Objects of this class are not created as standalone objects.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- IDLitIMessaging::AddOnNotifyObserver
- IDLitIMessaging::DoOnNotify
- IDLitIMessaging::ErrorMessage

- IDLitIMessaging::GetTool
- IDLitIMessaging::ProbeStatusMessage
- IDLitIMessaging::ProgressBar
- IDLitIMessaging::PromptUserText
- IDLitIMessaging::PromptUserYesNo
- IDLitIMessaging::RemoveOnNotifyObserver
- IDLitIMessaging::SignalError
- IDLitIMessaging::StatusMessage

## Version History

Introduced: 6.0

# IDLitIMessaging Properties

Objects of this class have no properties of their own.

# IDLitIMessaging::AddOnNotifyObserver

The IDLitIMessaging::AddOnNotifyObserver procedure method is used to register a specified iTool component object to receive messages generated by the DoOnNotify method of another specified iTool component object.

## Syntax

*Obj* -> [IDLitIMessaging::]AddOnNotifyObserver, *IdObserver, IdSubject*

## Arguments

### IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the OnNotify callback method, which is called when a notification message is dispatched to *IdObserver* by the DoOnNotify method of another iTool component object (usually the object specified by *IdSubject*). The OnNotify method has the following signature:

```
PRO ::OnNotify, idOriginator, idMessage, message
```

where

- *idOriginator* is the object identifier of the iTool component that is the source of the message
- *idMessage* is a string that identifies the type of message being sent
- *message* is the message itself.

In general, the *idMessage* string is used by the OnNotify method to determine what type of action to take. See “IDLitIMessaging::DoOnNotify” on page 2828 for additional details.

### IdSubject

A string value identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via IDLitIMessaging::DoOnNotify specifies *IdSubject* as the originator, the *IdObserver* object’s OnNotify method is called.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitIMessaging::DoOnNotify

The IDLitIMessaging::DoOnNotifiy procedure method is used to broadcast a notification message to iTool component objects that are observing the source of the message.

See the "IDLitIMessaging::AddOnNotifyObserver" on page 2826, and "IDLitIMessaging::RemoveOnNotifyObserver" on page 2837 methods for more information on notification messages.

See "iTool Messaging System" in Chapter 2 of the *iTool Developer's Guide* manual for a more in-depth discussion of notification.

## Syntax

*Obj* -> [IDLitIMessaging::]DoOnNotify, *IdOriginator*, *IdMesage*, *Value*

## Arguments

### IdOriginator

A string value identifying the item that is the source of the message. Normally, *IdOriginator* is the object identifier of the object that calls this method, but it can be any string value.

### IdMessage

A string that will uniquely identify the message being sent. The value of *IdMessage* is determined by the iTool developer; it is used by the OnNotify methods of any observer objects to determine what type of message has been received, and to act accordingly. For example, if a property value has changed, this argument might be set to the string `SETPROPERTY`.

### Value

Any value that is associated with the message being sent. For example, if a `SETPROPERTY` message was sent, *Value* might contain the name of the property changed. If no value is associated with the message, set this argument to a null string (`''`).

## Keywords

None

## Version History

Introduced: 6.0

# IDLitIMessaging::ErrorMessage

The IDLitIMessaging::ErrorMessage procedure method is used to display an error message to the user.

The actual method used to display the message to the user depends on the user interface in use. Normally, this method will display a modal dialog.

## Syntax

Obj -> [IDLitIMessaging::]ErrorMessage, *StrMessage*[, SEVERITY=*integer*] [, TITLE=*string*] [, /USE_LAST_ERROR]

## Arguments

### StrMessage

A scalar string or string array containing a description of the error.

## Keywords

### SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

### TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

### USE_LAST_ERROR

If this keyword is set, the system will use the information that was part of the last error signaled to the iTool. The last error may have been set either by a previous call to this method or by a call to the IDLitIMessaging::SignalError method.

## Version History

Introduced: 6.0

# IDLitIMessaging::GetTool

The IDLitIMessaging::GetTool function method returns an object reference to the iTool object associated with the object on which it is called.

## Syntax

*Result* = *Obj* -> [IDLitIMessaging::]GetTool()

## Return Value

Returns an object reference to the iTool object associated with the object on which the GetTool is called. If the object is not contained by an iTool, this function returns a null object reference.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitIMessaging::ProbeStatusMessage

The IDLitIMessaging::ProbeStatusMessage procedure method is used to display a status message to the user, which is displayed in a data-specific region of the user interface. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower right corner of the iTool window.

## Syntax

*Obj* -> [IDLitIMessaging::]ProbeStatusMessage, *StrMessage*

## Arguments

### StrMessage

A scalar string that is displayed in the data-specific status area.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitIMessaging::ProgressBar

The IDLitIMessaging::ProgressBar function method is used to display a progress bar to the user and update the displayed values.

On the initial call to this method, a dialog is displayed. The dialog remains active until the method is called with the /SHUTDOWN keyword.

The actual method used to display the message to the user depends on the user interface in use. Normally, the progress bar is displayed as a modal dialog.

## Syntax

*Result* = *Obj* -> [IDLitIMessaging::]ProgressBar(*StrMessage*[, PERCENT=*value*] [, /SHUTDOWN])

## Return Value

Returns 1 if the progress bar was displayed successfully, or 0 otherwise.

## Arguments

### StrMessage

A scalar string or string array containing a description of the action taking place.

## Keywords

### PERCENT

Set this keyword to a value between 0 and 100 that represents the “percentage complete” value to be shown on the progress bar.

### SHUTDOWN

If set, any progress bar that is being displayed is removed from the user interface.

## Version History

Introduced: 6.0

# IDLitIMessaging::PromptUserText

The IDLitIMessaging::PromptUserText function method is used to prompt the iTool user with a question and retrieve a text answer. The text answer is returned to the caller of this method via a supplied IDL variable.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

## Syntax

*Result* = *Obj* -> [IDLitIMessaging::PromptUserText(*StrPrompt*, *Answer* [, TITLE=*string*])

## Return Value

Returns 1 if the prompt was displayed and the user clicked the **OK** button. If the user clicks the **Cancel** button or dismisses the dialog, the return value is 0.

## Arguments

### StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

### Answer

A named variable that will contain the string value entered by the user.

## Keywords

### TITLE

Set this keyword to a string representing the title of the prompt. This value is placed in the title bar of the modal dialog.

## Version History

Introduced: 6.0

# IDLitIMessaging::PromptUserYesNo

The IDLitIMessaging::PromptUserYesNo function method is used to prompt the user with a yes or no question and return an answer.

The actual method used to prompt the user depends on the user interface in use. Normally, the prompt is displayed as a modal dialog.

## Syntax

*Result* = *Obj* -> [IDLitIMessaging::PromptUserYesNo(*StrPrompt*, *Answer* [, TITLE=*string*])

## Return Value

Returns 1 if the dialog executed properly and returned a value in the variable specified. You must check the value stored in the variable specified as the *Answer* argument to determine which button the user pressed.

## Arguments

### StrPrompt

A scalar string or string array containing a prompt for the user to respond to.

### Answer

A named variable that will contain 1 if the user answered Yes to the prompt and 0 if the user answered No.

## Keywords

### TITLE

Set this keyword to the title that should be displayed as part of the prompt. In most cases, this value is placed in the title bar of the modal dialog.

## Version History

Introduced: 6.0

# IDLitIMessaging::RemoveOnNotifyObserver

The IDLitIMessaging::RemoveOnNotifyObserver procedure method is used to un-register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object. This method reverses the action of calling the IDLitIMessaging::AddOnNotifyObserver method.

## Syntax

*Obj* -> [IDLitIMessaging::]RemoveOnNotifyObserver, *IdObserver*, *IdSubject*

## Arguments

### IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

### IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can be any scalar string.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitIMessaging::SignalError

The IDLitIMessaging::SignalError procedure method is used to signal an error in the system. No user interface is displayed to the user, but the error is registered with the system, made the current error, and recorded by the iTool log service (if enabled).

**Note**

If this method is used to signal an error, the IDLitIMessaging::ErrorMessage method can be called with the /USE_LAST_ERROR keyword to use the information set by this method.

## Syntax

*Obj* -> [IDLitIMessaging::]SignalError, *StrMessage* [, CODE=*integer*] [, SEVERITY=*integer*]

## Arguments

### StrMessage

A scalar string or string array containing a description of the error.

## Keywords

### CODE

Set this keyword to an integer that represents an error code that can be associated with the error. Error codes can be any integer value specified by the iTool developer.

### SEVERITY

Set this keyword to the severity code to use for this message. The system recognizes the following values:

- 0 = Informational
- 1 = Warning
- 2 = Error

## Version History

Introduced: 6.0

# IDLitIMessaging::StatusMessage

The IDLitIMessaging::StatusMessage procedure method is used to display a status message to the user. Unlike other messages that require immediate acknowledgement by the user, a status message is passive and no response is needed.

The actual method used to display the value to the user depends on the user interface in use. In a standard iTool included with IDL, this status message is displayed in the lower left corner of the iTool window.

## Syntax

*Obj* -> [IDLitIMessaging::]StatusMessage, *StrMessage*

## Arguments

### StrMessage

A scalar string that is displayed as a status message to the user.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulator

The IDLitManipulator class provides the base functionality of the iTools manipulator system. Most automation and functional capabilities of the manipulator system are provided by this class. Tasks performed by this class include:

- Selection operations and associated selection state management.
- Automated mouse cursor management (changing the cursor as the mouse traverses different items in the current visualization).
- System event settings management.
- Coordination between the manipulator and manipulator visualization system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulator__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitContainer

## Creation

See “IDLitManipulator::Init” on page 2854.

## Properties

Objects of this class have the following properties. See “IDLitManipulator Properties” on page 2842 for details on individual properties.

- BUTTON_EVENTS
- DEFAULT_CURSOR
- DESCRIPTION
- DISABLE
- DRAG_QUALITY
- KEYBOARD_EVENTS
- MOTION_EVENTS
- OPERATION_IDENTIFIER

- PARAMETER_IDENTIFIER
- TRANSIENT_DEFAULT
- TRANSIENT_MOTION
- TYPES
- VIEWS_ONLY
- VISUAL_TYPE

In addition, objects of this class inherit the properties of the superclass of this class.

## Methods

This class has the following methods:

- IDLitManipulator::Cleanup
- IDLitManipulator::CommitUndoValues
- IDLitManipulator::GetCursorType
- IDLitManipulator::GetProperty
- IDLitManipulator::Init
- IDLitManipulator::OnKeyboard
- IDLitManipulator::OnLoseCurrentManipulator
- IDLitManipulator::OnMouseDown
- IDLitManipulator::OnMouseMotion
- IDLitManipulator::OnMouseUp

- IDLitManipulator::SetProperty

In addition, this class inherits the methods of its superclass.

## Version History

Introduced: 6.0

# IDLitManipulator Properties

IDLitManipulator objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLitManipulator::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be set via IDLitManipulator::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLitManipulator::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## BUTTON_EVENTS

A boolean value controlling whether mouse button events are generated. If set, mouse button up and button down events will be dispatched to this manipulator. These events are enabled by default.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DEFAULT_CURSOR

A string containing the name of the default cursor for the manipulator. This is the name of the cursor that is displayed if no items are hit during mouse cursor motion. By default, the default cursor is set to `'ARROW'`.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## DESCRIPTION

A string representing the full name or description of this object.

| | |
|---|---|
| **Property Type** | STRING |

| **Name String** | Description | | |
|---|---|---|---|
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DISABLE

A boolean value indicating that the manipulator should be disabled. Disabling a manipulator prevents it from being chosen by a user or by the iTool system.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DRAG_QUALITY

An integer value representing the drawing quality to be used when the user clicks on a visualization and holds down the mouse button. Choosing a lower quality setting for drag operations may increase performance during the manipulation. When the user releases the mouse button, the visualization is redrawn at the original quality. The property can be set to any of the following values:

- 0 = Low
- 1 = Medium
- 2 = High

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | DRAG_QUALITY | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## KEYBOARD_EVENTS

A boolean value controlling whether keyboard events are generated. If set, keyboard events will be dispatched to the manipulator. These events are enabled by default.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## MOTION_EVENTS

A boolean value controlling whether motion events are generated. If set, motion events will be dispatched to this manipulator. These events are enabled by default.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## OPERATION_IDENTIFIER

A string identifier for the operation that is associated with the manipulator. This identifier specifies the operation that is used by the undo-redo system to transact the actions performed by this manipulator. If not specified, the manipulator actions are not recorded by the undo-redo system.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PARAMETER_IDENTIFIER

A string identifier specifying which parameter the operation should query when transacting the manipulator. If specified, this identifier is used in conjunction with the operation specified by the OPERATION_IDENTIFIER property to transact the operations performed by a manipulator. The parameter is primarily used to specify the property identifier for manipulators that change the values of properties.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TRANSIENT_DEFAULT

An integer value used to indicate that the manipulator is *transient*, which causes the system to automatically switch to the default manipulator when this manipulator's mouse actions are complete (that is, when the OnMouseUp method has been called) or when an end-of-keyboard-entry character (carriage return or escape key) is detected.

This property can be set to any of the following values:

- 0 = No transient behavior
- 1 = Mouse transient behavior is enabled. When a mouse button up is detected, the manipulation system will switch to the default manipulator for the system.
- 2 = Keyboard transient behavior is enabled. When a carriage return or escape key is pressed, the system will switch to the default manipulator for the system.
- 3 = Both keyboard and mouse transient behavior are enabled.

| **Property Type** | Enumerated List | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TRANSIENT_MOTION

A boolean value controlling whether transient motion events are generated. If set, the manipulator will generate motion events beginning when the OnMouseDown method is called and ending when the OnMouseUp method is called.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TYPES

A string array specifying the visualization types that this manipulator can operate on. If not specified, the manipulator will support all registered visualization types.

| **Property Type** | Vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** No |

## VIEWS_ONLY

A boolean value controlling the content of the manipulator hierarchy. If set, the manipulator will only operate on views in the manipulator hierarchy.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## VISUAL_TYPE

A string representing the type of selection visual to use with this manipulator. The VISUAL_TYPE property should match the corresponding property of an IDLitManipulatorVisual object. This high-level abstraction allows similar selection visuals to be assigned across multiple manipulators.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLitManipulator::Cleanup

The IDLitManipulator::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitManipulator::]Cleanup() (*In a subclass' Init method only.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulator::CommitUndoValues

The IDLitManipulator::CommitUndoValues function method is used to complete a transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the RecordUndoValues method.

When a manipulator interaction is complete, the manipulator should call this method, which in turn calls the RecordFinalValues method of the operation associated with the manipulator. The RecordFinalValues method records any information needed to undo the operation and places the information in the iTool's undo-redo transaction buffer.

For interactive manipulators, the CommitUndoValues method should be called by the OnMouseUp method.

**Note**

This method must be called on the current manipulator before being called on a superclass to ensure that the current selection state maintained by the manipulator is valid.

## Syntax

*Result* = *Obj* -> [IDLitManipulator::]CommitUndoValues([/UNCOMMENT])

## Return Value

Returns 1 if the commit was successful, or 0 otherwise.

## Arguments

None

## Keywords

### UNCOMMIT

Set this keyword to discard any pending information from a previous call to RecordUndoValues. The interaction is not recorded in the iTool's undo-redo transaction buffer.

## Version History

Introduced: 6.0

# IDLitManipulator::GetCursorType

The IDLitManipulator::GetCursorType function method retrieves the name of the cursor to display for the manipulator. The name of the cursor can be used with the SetCurrentCursor method of the IDLitWindow component.

The system will use this method to automatically change the cursor when the mouse traverses the contents of a visualization window. As the mouse transverses the window, the name for the hit item that is part of the current selection group is retrieved and passed to this routine. This action gives the manipulator the ability to change cursors depending on the area of the visualization the cursor is over.

## Syntax

*Result* = *Obj* -> [IDLitManipulator::]GetCursorType(*TypeIn*, *KeyMods*)

## Return Value

Returns a string containing the name of the cursor. If nothing is matched, an empty string is returned.

## Arguments

### TypeIn

A string variable containing the name of the portion of the selection visual for which the cursor is being requested.

### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values

1 = SHIFT Key

2 = CTRL Key

4 = CAPS LOCK key

8 = ALT key

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulator::GetProperty

The IDLitManipulator::GetProperty procedure method retrieves the value of an IDLitManipulator property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

## Syntax

*Obj* -> [IDLitManipulator::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLitManipulator Properties” on page 2842 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitManipulator::Init

The IDLitManipulator::Init function method initializes the IDLitManipulator object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitManipulator'[, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLitManipulator::]Init([, *PROPERTY*=*value*])
(*In a subclass' Init method only.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitManipulator Properties” on page 2842 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitManipulator::OnKeyboard

The IDLitManipulator::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow.

## Syntax

*Obj* -> [IDLitManipulator::]OnKeyboard, *Win*, *IsASCII*, *Character*, *Key Value*, *X*, *Y*, *Press*, *Release*, *KeyMods*

## Arguments

### Win

An object reference for the IDLitWindow from which the event came.

### IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

### KeyValue

The numeric value representing the key pressed if the key is non-ASCII. The possible numeric values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home
- 12 = End

### Character

A string containing the ASCII character of the key pressed.

### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

### Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

### Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulator::OnLoseCurrentManipulator

The IDLitManipulator::OnLoseCurrentManipulator procedure method is used when this manipulator is no longer the current manipulator in the system.

**Note**

This method is designed to be implemented by a subclass of IDLitManipulator, to perform any cleanup work necessary when a new manipulator is selected.

## Syntax

*Obj* -> [IDLitManipulator::]OnLoseCurrentManipulator

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulator::OnMouseDown

The IDLitManipulator::OnMouseDown procedure method is used when a mouse down event occurs on the target IDLitWindow. When applied, this method will perform a select operation on the current contents of the target IDLitWindow.

When overriding this method in a sub-class, this method is normally the first task performed so that the instance data of the object is properly setup.

## Syntax

*Obj* -> [IDLitManipulator::]OnMouseDown, *Win*, *X*, *Y*, *IButton*, *KeyMods*, *NClicks*

## Arguments

### Win

An object reference for the IDLitWindow from which the event came.

### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

### IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

### NClicks

An integer value representing number of clicks

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulator::OnMouseMotion

The IDLitManipulator::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down, this method manages the setting of the cursor on the IDLitWindow object.

If the manipulator is in the middle of a mouse-down, mouse-up transaction, the following instance data will be valid:

- ButtonPress — Set to the mouse buttons pressed.
- nSelectionList — The number of items selected.
- pSelectionList — A pointer to the objects current selected in the iTool.

These values can be helpful in performing actions in the manipulator and are automatically managed.

## Syntax

*Obj* -> [IDLitManipulator::]OnMouseMotion, *Win*, *X*, *Y*, *KeyMods*

## Arguments

### Win

An object reference for the IDLitWindow object from which the event came.

### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulator::OnMouseUp

The IDLitManipulator::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object.

When overriding this method in a sub-class, this method is normally the last task performed so that the instance data of the object is properly setup.

## Syntax

*Obj* -> [IDLitManipulator::]OnMouseUp, *Win*, *X*, *Y*, *IButton*

## Arguments

### Win

An object reference for the IDLitWindow object from which the event came.

### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

### IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulator::RecordUndoValues

The IDLitManipulator::RecordUndoValues function method is used to begin recording the transaction that is occurring as a result of the manipulator interaction. This method works in conjunction with the CommitUndoValues method.

To capture information for the undo-redo system of the tools framework, the initial and final values for the items that the manipulator will adjust must be recorded. This recording process is accomplished with the RecordUndoValues and CommitUndoValues methods.

These two methods make use of the operation that is associated with this manipulator (specified by the OPERATION_IDENTIFIER keyword to the Init method) to capture the needed information. When the RecordUndoValues method is called, the manipulator will retrieve the operation associated with this manipulator and call the RecordInitialValues method on this operation. The RecordInitialValues method is called with a command set, the list of currently selected items (which the manipulator is operating on) and the value that was provided by the PARAMETER_IDENTIFIER keyword to this manipulator. This method will record any information needed to undo the operation and place the values in the provided command set. See IDLitOperation for more information on operations.

For interactive manipulators, the RecordUndoValues method is called as part of the OnMouseDown method.

## Syntax

*Result* = *Obj* -> [IDLitManipulator::]RecordUndoValues()

## Return Value

Returns a 1 if recording was successful, or 0 otherwise.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulator::SetCurrentManipulator

The IDLitManipulator::SetCurrentManipulator procedure method sets the manipulator as the current manipulator in the system.

## Syntax

*Obj* -> [IDLitManipulator::]SetCurrentManipulator [, *Item*]

## Arguments

### Item

If this method is being called on a manipulator container object, *Item* can optionally be set to a string containing the relative object ID of the manipulator that should be set as the current manipulator. If *Item* is not supplied, the manipulator on which the method is called is set as the current manipulator.

## Keyword

None

## Version History

Introduced: 6.0

# IDLitManipulator::SetProperty

The IDLitManipulator::SetProperty procedure method sets the value of an IDLitManipulator property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

## Syntax

*Obj* -> [IDLitManipulator::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLitManipulator Properties” on page 2842 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitManipulatorContainer

The IDLitManipulatorContainer class allows for the construction of manipulator hierarchies. Building on the functionality provided by the IDLitManipulator class, the manipulator container implements the concept of a *current manipulator* for the items it contains.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatorcontainer__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitContainer

IDLitManipulator

## Creation

See "IDLitManipulatorContainer::Init" on page 2875.

## Properties

Objects of this class have the following properties. See "IDLitManipulatorContainer Properties" on page 2870 for details on individual properties.

- AUTO_SWITCH

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLitManipulatorContainer::Add
- IDLitManipulatorContainer::GetCurrent
- IDLitManipulatorContainer::GetCurrentManipulator
- IDLitManipulatorContainer::GetProperty
- IDLitManipulatorContainer::Init
- IDLitManipulatorContainer::OnKeyboard

- IDLitManipulatorContainer::OnMouseDown
- IDLitManipulatorContainer::OnMouseMotion
- IDLitManipulatorContainer::OnMouseUp
- IDLitManipulatorContainer::SetCurrent
- IDLitManipulatorContainer::SetCurrentManipulator
- IDLitManipulatorContainer::SetProperty

In addition, this class inherits the methods of its superclasses.

## Version History

Introduced: 6.0

# IDLitManipulatorContainer Properties

IDLitManipulatorContainer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the table are retrieved via IDLitManipulatorContainer::GetProperty. Properties with the word “Yes” in the “Init” column of the property table are set via IDLitManipulatorContainer::Init. Properties with the word “Yes” in the “Set” column in the property table are set via IDLitManipulatorContainer::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## AUTO_SWITCH

A boolean that, if set, causes the manipulator container to automatically change the value of its current child manipulator depending on the portion of the selection visual hit during a mouse down operation. This is performed by matching the name of the portion of the selection visual hit during the mouse down operation and the name of the sub-manipulators of this container.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLitManipulatorContainer::Add

The IDLitManipulatorContainer::Add procedure method is used to add a new manipulator to the container.

## Syntax

*Obj* -> [IDLitManipulatorContainer::]Add, *Manipulator*

## Arguments

### Manipulator

The new manipulator to add to this manipulator container. When completed, this manipulator is also set to the current manipulator for this manipulator container.

## Keywords

All keywords are passed to the IDL_Container superclass during the add operation.

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::GetCurrent

The IDLitManipulatorContainer::GetCurrent function method is used to get the object reference of the current manipulator of the container.

## Syntax

*Result* = *Obj* -> [IDLitManipulatorContainer::]GetCurrent()

## Return Value

Returns an object reference to the current manipulator for this container or a null object reference if no manipulators are contained by the container.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::GetCurrentManipulator

The IDLitManipulatorContainer::GetCurrentManipulator function method is used to get the current manipulator of the system. When applied, this function method causes a traversal of the manipulator hierarchy, returning the current leaf manipulator of the system.

## Syntax

*Result* = *Obj* -> [IDLitManipulatorContainer::]GetCurrentManipulator( [, /IDENTIFIER])

## Return Value

Returns an object reference to the current manipulator in the system. If the IDENTIFIER keyword is set, the routine will return the identifier for the current manipulator.

## Arguments

None

## Keywords

### IDENTIFIER

If set, the identifier of the current manipulator is returned. If not set, the current manipulator itself is returned.

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::GetProperty

The IDLitManipulatorContainer::GetProperty procedure method retrieves the value of an IDLitManipulatorContainer property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

## Syntax

*Obj* -> [IDLitManipulatorContainer::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLitManipulatorContainer Properties” on page 2870 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::Init

The IDLitManipulatorContainer::Init function method initializes the IDLitManipulatorContainer object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitManipulatorContainer'[, *PROPERTY=value*])

or

*Result = Obj ->* [IDLitManipulatorContainer::]Init([*PROPERTY=value*])
(*In a subclass' Init method only.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitManipulatorContainer Properties” on page 2870 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::OnKeyboard

The IDLitManipulatorContainer::OnKeyboard procedure method is used when a keyboard event occurs on the target IDLitWindow object. If the current child manipulator supports keyboard events, the OnKeyboard method for that manipulator is called.

## Syntax

*Obj* -> [IDLitManipulator::]OnKeyboard, *Win*, *IsASCII*, *Character*, *Key Value*, *X*, Y, *Press*, *Release*, *KeyMods*

## Arguments

### Win

An object reference for the IDLitWindow object from which the event came.

### IsASCII

A Boolean value to determine if the character is in the ASCII character set. This value is True if the character is in the ASCII character set.

### KeyValue

The numeric value representing a non-ASCII key pressed. The possible values are:

- 1 = Shift
- 2 = Control
- 3 = Caps Lock
- 4 = Alt
- 5 = Left
- 6 = Right
- 7 = Up
- 8 = Down
- 9 = Page Up
- 10 = Page Down
- 11 = Home

- 12 = End

### Character

A string containing the ASCII character of the key pressed

### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

### Press

A Boolean value to determine if the current event is a key press. This value is True if the event is pressing the key

### Release

A Boolean value to determine if the current event is a key release. This value is True if event is releasing the key

### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::OnMouseDown

The IDLitManipulatorContainer::OnMouseDown procedure method is used when a mouse down event occurs on the target IDLitWindow object. When applied and auto-switch mode is enabled in the container, the current child manipulator will be determined by matching the type of the visualization hit with the identifier of the sub-manipulators contained in this container. If no match is made, the default child manipulator is selected. Once complete, normal processing continues.

If the current sub-manipulator supports mouse button events, its OnMouseDown method is called.

## Syntax

*Obj* -> [IDLitManipulatorContainer::]OnMouseDown, *Win*, *X*, *Y*, *IButton*, *KeyMods*, *NClicks*

## Arguments

### Win

An object reference for the IDLitWindow object from which the event came.

### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

### IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

### NClicks

An integer value representing number of clicks

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::OnMouseMotion

The IDLitManipulatorContainer::OnMouseMotion procedure method implements the OnMouseMotion method. If no mouse button is down and auto-switch mode is enabled, this method manages the setting of the cursor on the IDLitWindow object. Otherwise if the current sub-manipulator supports motion events, its OnMouseMotion method is called.

## Syntax

*Obj* -> [IDLitManipulatorContainer::]OnMouseMotion, *Win, X, Y, KeyMods*

## Arguments

### Win

An object reference for the IDLitWindow object from which the event came.

### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

### KeyMods

An integer representing the keyboard modifiers for the button. These can have one of the following values:

- 1 = SHIFT key
- 2 = CTRL key
- 4 = CAPS LOCK key
- 8 = ALT key

## Keywords

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::OnMouseUp

The IDLitManipulatorContainer::OnMouseUp procedure method is used when a mouse up event occurs on the target IDLitWindow object. When applied, the container will call the OnMouseUp method of the current child manipulator if that manipulator supports button events.

## Syntax

*Obj* -> [IDLitManipulatorContainer::]OnMouseUp, *Win*, *X*, *Y*, *IButton*

## Arguments

### Win

An object reference for the IDLitWindow object from which the event came.

### X

A floating-point value representing the *x*-coordinate in the window's coordinates.

### Y

A floating-point value representing the *y*-coordinate in the window's coordinates.

### IButton

An integer value representing the mask for the button pressed:

- 1 = Left
- 2 = Middle
- 4 = Right

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::SetCurrent

The IDLitManipulatorContainer::SetCurrent procedure method is used to set a manipulator within the container to be the current manipulator.

## Syntax

*Obj* -> [IDLitManipulatorContainer::]SetCurrent, *Manipulator*

## Arguments

### Manipulator

The object reference of the manipulator to be set as current in the manipulator container. This manipulator must be contained in the container or an error is thrown.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::SetCurrentManipulator

The IDLitManipulatorContainer::SetCurrentManipulator procedure method is used to set the current child manipulator in a manipulator hierarchy. When applied, the manipulator will use the provided identifier to call the SetCurrentManipulator on the target child manipulator. If the provided identifier is null, the default manipulator is set as current.

## Syntax

*Obj* -> [IDLitManipulatorContainer::]SetCurrentManipulator, *Identifier*

## Arguments

### Identifier

Either the identifier for the manipulator that is to be made current in the system or its object reference.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulatorContainer::SetProperty

The IDLitManipulatorContainer::SetProperty procedure method sets the value of an IDLitManipulatorContainer property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

## Syntax

*Obj* -> [IDLitManipulator::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLitManipulatorContainer Properties” on page 2870 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitManipulatorManager

The IDLitManipulatorManager class is a specialization of a IDLitManipulatorContainer class that acts as the root of a manipulator hierarchy. In addition, this class provides the functionality that allows it to interface with external elements in the iTool system.

This class is written in the IDL language. Its source code can be found in the file `idlitmanipulatormanager__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitManipulatorContainer

## Creation

See "IDLitManipulatorManager::Init" on page 2891.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- IDLitManipulatorManager::Add
- IDLitManipulatorManager::AddManipulatorObserver
- IDLitManipulatorManager::Init
- IDLitManipulatorManager::RemoveManipulatorObserver

In addition, this class inherits the methods of its superclass.

## Version History

Introduced: 6.0

# IDLitManipulatorManager Properties

Objects of this class have no properties of their own, but do have properties inherited from its superclass.

# IDLitManipulatorManager::Add

The IDLitManipulatorManager::Add procedure method is used to add manipulators to the manipulator manager. This method uses the add functionality of its superclass to add the given manipulator to the hierarchy and checks the default keyword to determine if the given manipulator should be treated as the default for the system.

## Syntax

*Obj* -> [IDLitManipulatorManager::]Add, *Manipulator* [, /DEFAULT]

## Arguments

### Manipulator

A manipulator to add to the manipulator manager

## Keywords

### DEFAULT

If set, the added manipulator is made default for the system. This is primarily used with manipulators that implement transient behavior (mouse or keyboard). When these manipulators complete interaction, the current manipulator of the system is set to the default manipulator.

## Version History

Introduced: 6.0

# IDLitManipulatorManager::AddManipulatorObserver

The IDLitManipulatorManager::AddManipulatorObserver procedure method is used to add an observer to the manipulator system. An observer object is notified when the current manipulator of the manipulator hierarchy changes.

To perform this action, the observer object must implement the method OnManipulatorChange. This method has the following signature:

```
PRO ObjectClass::OnManipulatorChange, Subject
```

Where *Subject* is this class, the manipulator manager.

## Syntax

*Obj* -> [IDLitManipulatorManager::]AddManipulatorObserver, *Observer*

## Arguments

### Observer

A scalar or array of objects that implement the manipulator observer interface.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulatorManager::Init

The IDLitManipulatorManager::Init function method initializes the IDLitManipulatorManager object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitManipulatorManager' [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLitManipulatorManager::]Init([*PROPERTY=value*])
(*In a subclass' Init method only.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitManipulatorManager Properties” on page 2888 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitManipulatorManager::RemoveManipulatorObserver

The IDLitManipulatorManager::RemoveManipulatorObserver procedure method is used to remove a manipulator observer from the manipulator object. If the value for the *Observer* argument is not a valid manipulator observer, this method does nothing and no error is reported.

## Syntax

*Obj* -> [IDLitManipulatorManager::]RemoveManipulatorObserver, *Observer*

## Arguments

### Observer

A scalar or array of objects that are to be removed from this container

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulatorVisual

The IDLitManipulatorVisual class implements methods that allow the iTool developer to create visual elements that are associated with an interactive manipulator. IDLitManipulatorVisual objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

## Superclasses

This class has no superclasses.

## Creation

See "IDLitManipulatorVisual::Init" on page 2899.

## Properties

Objects of this class have the following properties. See "IDLitManipulatorVisual Properties" on page 2895 for details on individual properties.

- UNIFORM_SCALE
- VISUAL_TYPE

## Methods

This class has the following methods:

- IDLitManipulatorVisual::Cleanup
- IDLitManipulatorVisual::GetProperty
- IDLitManipulatorVisual::Init
- IDLitManipulatorVisual::SetProperty

## Version History

Introduced: 6.0

# IDLitManipulatorVisual Properties

IDLitManipulatorVisual objects have the following properties. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLitManipulatorVisual::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be set via IDLitManipulatorVisual::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLitManipulatorVisual::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## UNIFORM_SCALE

Set this property to create a manipulator visual which should be scaled equally in all three dimensions when fitting the manipulator visual to the size of its associated visualization. If this property is not set, then the manipulator visual will use a different scale factor in the *x*, *y*, and *z* dimensions, in order to match its associated visualization.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not applicable* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## VISUAL_TYPE

Set this keyword to a string representing the manipulator visual type. The VISUAL_TYPE property should match the corresponding string in its associated IDLitManipulator object. When a new manipulator is selected in an iTool, the VISUAL_TYPE property on the manipulator object is used to search for a corresponding manipulator visual.

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not applicable* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLitManipulatorVisual::Cleanup

The IDLitManipulatorVisual::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitManipulatorVisual::]Cleanup (*only in subclass' Cleanup method*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitManipulatorVisual::GetProperty

The IDLitManipulatorVisual::GetProperty procedure method retrieves the value of an IDLitManipulatorVisual property.

## Syntax

*Obj* -> [IDLitManipulatorVisual::]GetProperty

## Arguments

None

## Keywords

Any property listed under “IDLitManipulatorVisual Properties” on page 2895 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitManipulatorVisual::Init

The IDLitManipulatorVisual::Init function method initializes the IDLitManipulatorVisual object, and should be called by the Init method of a subclass.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitManipulatorVisual'[, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLitManipulatorVisual::]Init([, *PROPERTY*=*value*])
(*In a subclass' Init method only.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLitManipulatorVisual Properties" on page 2895 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitManipulatorVisual::SetProperty

The IDLitManipulatorVisual::SetProperty procedure method sets the value of an IDLitManipulatorVisual property.

## Syntax

*Obj* -> [IDLitManipulatorVisual::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLitManipulatorVisual Properties” on page 2895 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitOperation

The IDLitOperation class is the basis for all iTool operations. It defines how an operation is executed and how information about the operation is recorded for the command transaction (undo-redo) system.

An operation encapsulates a specific set of tasks that perform some atomic action on a target. Between executions of the operation, no state values other than properties of the operation itself are maintained by this object. Two major areas of functionality are provided: automated operation execution and undo-redo capabilities.

Once defined, the operation object exposes a set of properties whose values can affect how the operation executes. The properties that an operation exposes are valid across multiple executions; properties can be set interactively via the Operation browser or programmatically using the operation object's GetProperty and SetProperty methods.

**Note**

For operations that act directly on data items that underlie a visualization, consider basing your operation class on the IDLitDataOperation class. IDLitDataOperation is a subclass of IDLitOperation that automates many of the target-selection and undo-redo mechanisms that must be provided by operation classes based directly on this class.

For a detailed discussion of both the IDLitOperation and IDLitDataOperation classes, see Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitoperation__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitComponent

IDLitIMessaging

## Creation

See "IDLitOperation::Init" on page 2911.

## Properties

Objects of this class have the following properties. See “IDLitOperation Properties” on page 2905 for details on individual properties.

- EXPENSIVE_COMPUTATION
- REVERSIBLE_OPERATION
- SHOW_EXECUTION_UI
- TYPES

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLitOperation::Cleanup
- IDLitOperation::DoAction
- IDLitOperation::GetProperty
- IDLitOperation::Init
- IDLitOperation::RecordFinalValues
- IDLitOperation::RecordInitialValues
- IDLitOperation::RedoOperation
- IDLitOperation::SetProperty
- IDLitOperation::UndoOperation

In addition, this class inherits the methods of its superclasses.

## Examples

See Chapter 7, “Creating an Operation” in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

## See Also

IDLitDataOperation

# IDLitOperation Properties

IDLitOperation objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the properties table can be retrieved via IDLitOperation::GetProperty. Properties with the word “Yes” in the “Init” column of the properties table can be initialized via IDLitOperation::Init. Properties with the word “Yes” in the “Set” column of the properties table can be set via IDLitOperation::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## EXPENSIVE_COMPUTATION

Set this property to 1 to indicate that a computation of the operation is *expensive*. Expensive computations are those that require significant memory or processing time to execute. Individual operations should use the value of this property to determine whether the results of the operation should be cached to avoid re-execution when undoing or redoing.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** No |

## REVERSIBLE_OPERATION

Set this property to 1 to indicate that the operation is *reversible*. When an operation is reversible, it can be undone by applying an operation rather than restoring a stored value. Rotation by a specified angle is an example of an operation that is reversible, since applying another rotation by the complementary angle returns the visualization to its original state. Individual operations should use the value of this property to determine how the operation should be undone.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** No |

## SHOW_EXECUTION_UI

Set this property to 1 to indicate that the operation should display a user interface element such as a dialog when the operation is executed. The flag is ignored by the IDLitOperation itself, but can be used by subclasses (notably IDLitDataOperation) to determine when to display user interface elements.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | Show Dialog | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** No |

## TYPES

Set this property to a string or an array of strings indicating the types of data to which the operation can be applied. iTools data types are described in Chapter 3, “Data Management” in the *iTool Developer’s Guide* manual. Set this property to a null string (`''`) to specify that the operation can be applied to all types of data.

| | | | |
|---|---|---|---|
| **Property Type** | User Defined | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLitOperation::Cleanup

The IDLitOperation::Cleanup procedure method performs all cleanup on the object.

**Note**

An operation based on the IDLitOperation class need not implement this method if the operation does not allocate any pointers or object references of its own.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitOperation::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitOperation::DoAction

The IDLitOperation::DoAction function method is called when an operation is requested by the iTools system, either as the result of a user action such as selection of a menu item or toolbar button, or by another operation.

**Note**

Every operation based directly on the IDLitOperation class must implement its own DoAction method. See Chapter 7, “Creating an Operation” in the *iTool Developer’s Guide* manual for details.

A specific operation class’ implementation of this method must create an initialized IDLitCommandSet object, execute the operation, and return the command set object to the caller. DoAction can also call the IDLitOperation::RecordInitialValues and IDLitOperation::RecordFinalValues methods to ensure that the appropriate values are committed to the undo-redo transaction buffer.

If your operation changes the values of its own registered properties (as the result of user interaction with a dialog or other interface element called by DoUIService, for example), be sure to call the RecordInitialValues and RecordFinalValues methods. This ensures that changes made through the dialog are placed in the undo-redo transaction buffer.

**Note**

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo/Redo mechanism.

# Syntax

*Result* = *Obj* -> [IDLitOperation::]DoAction(*Tool*)

# Return Value

If successful, this method returns an IDLitCommandSet object or array of IDLitCommandSet objects that will be placed in the iTool’s command buffer. The command set object will be passed to the UndoOperation and RedoOperation methods as necessary. If not successful, this method returns a null object reference.

**Note**

The OPERATION_IDENTIFIER property of the command set object returned by the IDLitOperation::DoAction method is set equal to the full identifier of the operation itself. This implies that UndoOperation and RedoOperation methods exist for the operation, and that they implement the necessary undo and redo mechanisms. If you are overriding this method, you must either ensure that the appropriate UndoOperation and RedoOperation methods exist, or manually create an IDLitCommandSet object with the OPERATION_IDENTIFIER set to another operation that is capable of undoing or redoing the changes made by your method.

# Arguments

## Tool

An object reference to the iTool object on which the operation executes.

# Keywords

None

# Version History

Introduced: 6.0

# IDLitOperation::GetProperty

The IDLitOperation::GetProperty procedure method retrieves the value of a property or group of properties of an operation object.

**Note**

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

## Syntax

*Obj* -> [IDLitOperation::]GetProperty [, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under "IDLitOperation Properties" on page 2905 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Example

To retrieve the value of the REVERSIBLE_OPERATION property:

```
Obj -> IDLitOperation::GetProperty, REVERSIBLE_OPERATION = rev
```

## Version History

Introduced: 6.0

# IDLitOperation::Init

The IDLitOperation::Init function method initializes the IDLitOperation object and sets properties that define the behavior the operation provides.

**Note**

An operation based on the IDLitOperation class *must* implement this method. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

**Note**

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitOperation' [, *PROPERTY*=*variable*] )

or

*Result* = *Obj* -> [IDLitOperation::]Init( [, *PROPERTY*=*variable*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitOperation Properties” on page 2905 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitOperation::RecordFinalValues

The IDLitOperation::RecordFinalValues function method records the information needed to redo an operation. Information about individual operations is recorded in IDLitCommand objects, which are in turn stored in an IDLitCommandSet object that is passed to the IDLitOperation::UndoOperation and IDLitOperation::RedoOperation methods.

**Note**

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the appropriate IDLitCommand object from the IDLitCommandSet object specified as the first parameter,
- Record any information necessary to redo the operation in the IDLitCommand object,
- Return 1 for success.

## Syntax

*Result* = *Obj* `->` [IDLitOperation::]RecordFinalValues(*CommandSet*, *Targets* [, *IdProperty*] )

## Return Value

The return value is 1 if the final values were recorded successfully, or zero otherwise.

## Arguments

### CommandSet

An IDLitCommandSet object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the IDLitOperation::DoAction method, which then calls the RecordInitialValues method to store the initial state of the target object.

### Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the IDLitTool::GetSelectedItems method.

### IdProperty

A property identifier string specifying the target property or parameter of the operation.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitOperation::RecordInitialValues

The IDLitOperation::RecordInitialValues function method records the information needed to undo an operation. Information about individual operations is recorded in IDLitCommand objects, which are in turn stored in an IDLitCommandSet object that is passed to the IDLitOperation::UndoOperation and IDLitOperation::RedoOperation methods.

**Note**

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Create an IDLitCommand object, setting its TARGET_IDENTIFIER property to the identifier of the target object,
- Record any information necessary to redo the operation in the IDLitCommand object,
- Add the IDLitCommand object to the IDLitCommandSet object specified as the first parameter,
- Return 1 for success.

## Syntax

*Result* = *Obj* `->` [IDLitOperation::]RecordInitialValues(*CommandSet*, *Targets* [, *IdProperty*])

## Return Value

The return value is 1 if the initial values were recorded successfully, or zero otherwise.

# Arguments

## CommandSet

An IDLitCommandSet object that encapsulates all information recorded for this execution of the operation. The command set object is generally created by the IDLitOperation::DoAction method, which then calls the RecordInitialValues method to store the initial state of the target object.

## Targets

An array of objects that are the targets of this operation. In most cases, the target objects are the currently selected objects, as returned by the IDLitTool::GetSelectedItems method.

## IdProperty

A property identifier string specifying the target property or parameter of the operation.

# Keywords

None

# Version History

Introduced: 6.0

# IDLitOperation::RedoOperation

The IDLitOperation::RedoOperation function method is called by the iTool system when the user requests the re-execution of an operation (usually by selecting Redo from the iTool Edit menu or toolbar).

**Note**

An operation based on the IDLitOperation class *must* implement this method. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

**Note**

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the IDLitCommand objects from the IDLitCommandSet object passed as the first argument,
- For each IDLitCommand object, retrieve the target of the operation, using the TARGET_IDENTIFIER property,
- Retrieve the stored information and use it to redo the operation,
- Return 1 for success.

# Syntax

*Result* = *Obj* -> [IDLitOperation::]RedoOperation(*CommandSet*)

# Return Value

The return value is 1 if the operation was redone successfully, or zero otherwise.

# Arguments

## CommandSet

An IDLitCommandSet object that contains all the IDLitCommand objects that were stored during the original execution of the operation.

## Keywords

None

## Version History

Introduced: 6.0

## See Also

IDLitOperation::RecordFinalValues, IDLitOperation::RecordInitialValues, IDLitOperation::UndoOperation

# IDLitOperation::SetProperty

The IDLitOperation::SetProperty procedure method sets the value of a property or group of properties for the operation.

**Note**

An operation based on the IDLitOperation class *must* implement this method if the operation defines one or more properties not inherited from the superclass. See Chapter 7, “Creating an Operation” in the *iTool Developer’s Guide* manual for details.

## Syntax

*Obj* -> [IDLitOperation::]SetProperty [, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLitOperation Properties” on page 2905 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitOperation::UndoOperation

The IDLitOperation::UndoOperation function method is called by the iTool system when the user requests the un-execution of an operation (usually by selecting Undo from the iTool Edit menu or toolbar).

**Note**

An operation based on the IDLitOperation class *must* implement this method. See Chapter 7, "Creating an Operation" in the *iTool Developer's Guide* manual for details.

**Note**

If you are creating an operation that acts directly on the data that underlies a visualization, consider using the IDLitDataOperation class rather than the IDLitOperation class. IDLitDataOperation provides additional automation of the Undo and Redo mechanisms.

If this method is implemented for an operation, it should do the following:

- Retrieve the IDLitCommand objects from the IDLitCommandSet object passed as the first argument,
- For each IDLitCommand object, retrieve the target of the operation, using the TARGET_IDENTIFIER property,
- Retrieve the stored information and use it to undo the operation,
- Return 1 for success.

# Syntax

*Result* = *Obj* -> [IDLitOperation::]UndoOperation(*CommandSet*)

# Return Value

The return value is 1 if the operation was undone successfully, or zero otherwise.

# Arguments

## CommandSet

An IDLitCommandSet object that contains all the IDLitCommand objects that were stored during the original execution of the operation.

## Keywords

None

## Version History

Introduced: 6.0

## See Also

IDLitOperation::RecordFinalValues, IDLitOperation::RecordInitialValues, IDLitOperation::RedoOperation

# IDLitParameter

The IDLitParameter class implements parameter management methods that allow parameter names to be associated with IDLitData objects. IDLitParameter objects are not intended to be created as standalone entities; rather, this class should be included as the superclass of another iTool class.

**Note**

In the iTools system, management of data parameters is handled by the IDLitVisualization class, of which the IDLitParameter class is a superclass. In practice, this means that if you need to override any methods of the IDLitParameter class, you will do so in the definition of your visualization class. In most cases, the only method you will need to implement is the OnDataChangeUpdate method.

When an object that inherits from the IDLitParameter class is created, the following are created as part of the new object's instance data:

- An IDL_Container object, which will contain parameter names for all parameters registered with the object. Parameter names are discussed in "Parameters" in Chapter 3 of the *iTool Developer's Guide* manual,
- A pointer to a string array containing the parameter names for all parameters registered with the object,
- An IDLitParameterSet object, which will contain the actual IDLitData objects associated with the object's parameters. Parameter sets are discussed in "Parameter Sets" in Chapter 3 of the *iTool Developer's Guide* manual, and in "IDLitParameterSet" on page 2939.

This class is written in the IDL language. Its source code can be found in the file `idlitparameter__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

This class has no superclasses.

## Creation

The objects of this class are not created as standalone objects.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- IDLitParameter::Cleanup
- IDLitParameter::GetParameter
- IDLitParameter::GetParameterSet
- IDLitParameter::Init
- IDLitParameter::OnDataChangeUpdate
- IDLitParameter::OnDataDisconnect
- IDLitParameter::RegisterParameter
- IDLitParameter::SetData
- IDLitParameter::SetParameterSet

## Version History

Introduced: 6.0

# IDLitParameter Properties

Objects of this class have no properties of their own.

# IDLitParameter::Cleanup

The IDLitParameter::Cleanup procedure method removes the *data observer* from each data object in the visualization object's parameter set, and cleans up the objects and pointers defined to hold parameter data when the visualization object was created.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitParameter::]Cleanup() (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitParameter::GetParameter

The IDLitParameter::GetParameter function method retrieves the IDLitData object associated with a registered parameter.

## Syntax

*Result* = *Obj* -> [IDLitParameter::]GetParameter(*Name* [, /ALL] [, COUNT=*variable*] )

## Return Value

Returns an object reference to the IDLitData object associated with the specified parameter name, or a null object reference if no data objects are associated with the specified parameter name.

## Arguments

### Name

A scalar string containing the parameter name associated with the IDLitData object to be retrieved.

## Keywords

### ALL

Set this keyword to retrieve all of the IDLitData objects contained in the visualization object's IDLitParameterSet object.

### COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

## Version History

Introduced: 6.0

# IDLitParameter::GetParameterSet

The IDLitParameter::GetParameterSet function method returns a reference to the IDLitParameterSet object associated with the visualization object.

## Syntax

*Result* = *Obj* -> [IDLitParameter::]GetParameterSet([, /DEEP_COPY)

## Return Value

Returns an IDLitParameterSet object that contains the IDLitData objects and associated parameter names for the visualization object.

## Arguments

None

## Keywords

### DEEP_COPY

Set this keyword to cause GetParameterSet to return a parameter set that contains *copies* of the IDLitData objects used by the visualization object's registered parameters. If this keyword is not set, the parameter set returned by this function will contain *references* to the IDLitData objects that are being used by the visualization object's registered parameters.

## Version History

Introduced: 6.0

# IDLitParameter::Init

The IDLitParameter::Init function method initializes object instance fields that contain parameter data. Since the IDLitParameter class is always used as a superclass of another class (IDLitVisualization, in the context of the iTool system), initializing this class simply initializes the objects and pointers used to store parameter information in the IDLitVisualization object.

**Note**

Init methods are special lifecycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Result* = *Obj* -> [IDLitParameter::]Init() (*Only in subclass' Init method.*)

## Return Value

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitParameter::OnDataChangeUpdate

The IDLitParameter::OnDataChangeUpdate method is called when a data value has been updated or a new data object has been associated with the visualization object.

**Note**

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

## Syntax

*Obj* `->` [IDLitParameter::]OnDataChangeUpdate, *Data*, *ParameterName*

## Arguments

### Data

An object reference to the IDLitData object or the IDLitParameterSet object containing the changed parameter data. If *Data* is an IDLitParameterSet object, the *ParameterName* argument must be set to the string `'<PARAMETER SET>'`.

### ParameterName

An upper-case scalar string containing the name of the parameter that has changed. The parameter specified via this argument must be registered with the visualization object. If *oData* is an IDLitParameterSet object, this argument must be set to the string `'<PARAMETER SET>'`.

## Keywords

None

# Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following code handles a parameter named Z:

```
PRO MyVis::OnDataChangeUpdate, oData, ParameterName

CASE ParameterName OF
   'Z': BEGIN
      ;; do something with the z data
   END
   '<PARAMETER SET>': BEGIN
      oZ = oData -> GetByName('Z')
      ;; do something with the z data.
   END
ENDCASE

END
```

**Note**

The Z parameter is handled twice — once if supplied as an individual IDLitData object and once if supplied via the IDLitParameterSet object.

See "Creating an OnDataChangeUpdate Method" in the section "Creating a New Visualization Type" in Chapter 6 of the *iTool Developer's Guide* manual for more discussion of the OnDataChangeUpdate method.

# Version History

Introduced: 6.0

# IDLitParameter::OnDataDisconnect

The IDLitParameter::OnDataDisconnect procedure method is called when a data value has been disconnected from a parameter. The general idea is that when a data item is disassociated from a visualization parameter, one or more properties of the visualization may need to be reset to reasonable default values.

**Note**

A visualization class based on the IDLitVisualization class *must* implement this method in order for changes or additions to the data parameters to be updated automatically in the resulting visualizations.

## Syntax

*Obj* `->` [IDLitParameter::]OnDataDisconnect, *ParameterName*

## Arguments

### ParameterName

An upper-case string containing the name of the parameter that was disconnected. The parameter must have been previously registered with the visualization.

## Keywords

None

## Example

Normally, an implementation of this method will contain a CASE statement that switches based on the value of the *ParameterName* argument. For example, the following sample code performs some action when the parameter name is `TEXTURE`:

```
PRO MyVis::OnDataDisconnect, ParameterName

CASE ParameterName OF
   'TEXTURE': BEGIN
   ;; do something to remove the ref. of the texture
   END
ENDCASE

END
```

## Version History

Introduced: 6.0

# IDLitParameter::RegisterParameter

The IDLitParameter::RegisterParameter procedure method registers a parameter with the visualization object. Registered parameters are displayed in the iTool parameter editor dialog, allowing users to interactively assign data values to individual visualization parameters.

## Syntax

*Obj* -> [IDLitParameter::]RegisterParameter, *Name* [, /BY_VALUE] [, DESCRIPTION=*string*] [, /INPUT] [, /OPTARGET] [, /OPTIONAL] [, /OUTPUT] [, TYPES=*string*]

## Arguments

### Name

Set this argument to a string specifying the name of the parameter.

## Keywords

### BY_VALUE

Set this keyword to indicate that this parameter is a by-value parameter. If a parameter is marked as by value, when data is associated with it a copy of the data is made and managed by this class.

### DESCRIPTION

Set this keyword to a string giving the full name or description of this object.

### INPUT

Set this keyword to indicate that this is an input parameter.

### OPTARGET

Set this keyword to indicate that this parameter may be the target of any operations.

### OPTIONAL

If this keyword is set, then this parameter is an optional parameter, and it is not required to be set. The default is OPTIONAL=0, indicating that it is required to be set.

### OUTPUT

Set this keyword to indicate that this is an output parameter.

### TYPES

Set this keyword to a scalar string or string array giving the data types that correspond to this parameter. See "iTool Data Types" in Chapter 3 of the *iTool Developer's Guide* manual for more on parameter data types.

## Version History

Introduced: 6.0

# IDLitParameter::SetData

The IDLitParameter::SetData function method is used to set data in this interface, associating a data object with a given parameter. This method can automatically perform type matching to determine which parameter to associate with a particular parameter or the user can specify a parameter name.

If a parameter name is provided by the user via the PARAMETER_NAME keyword, this method will query the given data object for a data item that is of one of the types supported by this parameter and associate the found data item with the parameter. This could be the data object provided or if the data object contains other data objects, one of its children. If a type match doesn't occur, the method will return 0.

If no parameter name is provided, this method will start with the first available parameter (non-associated parameters, starting with op-targets first) and attempt to perform a data type match. When a data type match between the parameter and the provided data item (or one of its contained items) the association between the two are made.

When a data match has been made, this object is made an observer of the data object and if the NO_UPDATE keyword is not set, the OnDataChangeUpdate() method is called on this object.

If a type match is found, but the given parameter already has a data object associated with it, the type match will continue.

If a match cannot be found, a value of 0 is returned.

## Syntax

*Result* = *Obj* -> [IDLitParameter::]SetData(*Data* [, /BY_VALUE] [, PARAMETER_NAME=*string*] [, /NO_UPDATE]

## Return Value

Returns 1 if the IDLitData object was successfully matched with a parameter registered with the visualization object, or 0 otherwise.

## Arguments

### Data

An IDLitData object to be matched with a parameter registered with the visualization object.

# Keywords

## BY_VALUE

Set this keyword to cause *Data* to be copied and managed by the visualization's parameter interface. If this keyword is not set, the data object is managed by the iTool system, and can be altered by other iTools.

## NO_UPDATE

Set this keyword to prevent the OnDataChangeUpdate method from being called when *Data* is associated with one of the visualization object's registered parameters. If this keyword is not set, the OnDataChangeUpdate method is called, providing the opportunity for subclasses of the visualization object to be notified that data associated with the parameter interface has changed.

## PARAMETER_NAME

Set this keyword to a scalar string containing the name of the registered parameter with which *Data* should be associated. If the iTool data type of the data contained in *Data* does not match one of the data types supported by the specified registered parameter, *Data* will not be associated with the registered parameter and this function will return zero.

# Version History

Introduced: 6.0

# IDLitParameter::SetParameterSet

The IDLitParameter::SetParameterSet function method is used to associate an IDLitParameterSet object with the visualization object's parameter interface. IDLitData objects contained in the parameter set object will be associated with the registered parameters of the visualization object, either based on the parameter names included in the parameter set object or on the iTool data types of the data objects. When the association of the parameter set's data objects with the visualization object's registered parameters is complete, the OnDataChangeUpdate method is called with the IDLitParameterSet object and the string `'<PARAMETER SET>'` as the arguments.

**Note**

When this method is called, the IDLitParameterSet object created when the visualization object was initialized will be disassociated from the object's parameter interface. This means that any individual data objects or parameter names previously added to the initial parameter set object will also be disassociated from the visualization object's parameter interface.

This method will not destroy or delete the information contained in the specified IDLitParameterSet object.

# Syntax

*Result* = *Obj* `->` [IDLitParameter::]SetParameterSet(*ParamSet*)

# Return Value

Returns 1 if the IDLitParameterSet object was successfully associated with the visualization object's parameter interface, or 0 otherwise.

# Arguments

## ParamSet

An IDLitParameterSet object to be associated with the visualization object's parameter interface.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitParameterSet

The IDLitParameterSet class is a specialized subclass of the IDLitDataContainer class that provides the ability to associate names with the contained IDLitData objects. This association allows the iTool developer to package a set of data parameters in a single container, which is then provided to the iTools system for processing a display.

In addition to providing a mechanism for associating IDLitData objects with parameter names, the IDLitParameterSet class allows you to incorporate an IDLitData object for which no parameter name is provided. These *auxiliary data* items are treated as parameters for which the parameter name is a null string (`''`). The auxiliary data mechanism allows you to associate any amount of data with a parameter set without the need to define parameter names.

This class is written in the IDL language. Its source code can be found in the file `idlitparameterset__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitDataContainer

## Creation

See “IDLitParameterSet::Init” on page 2951.

## Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

## Methods

This class has the following methods:

- IDLitParameterSet::Add
- IDLitParameterSet::Cleanup
- IDLitParameterSet::Copy
- IDLitParameterSet::Get

- IDLitParameterSet::GetByName
- IDLitParameterSet::GetParameterName
- IDLitParameterSet::Init
- IDLitParameterSet::Remove

In addition, this class inherits the methods of its superclass.

## Examples

See Chapter 3, “Data Management” in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

# IDLitParameterSet Properties

Objects of this class have no properties of their own, but do have properties inherited from the superclass.

# IDLitParameterSet::Add

The IDLitParameterSet::Add procedure method is used to add a data object to the parameter set.

# Syntax

*Obj* `->` [IDLitParameterSet::]Add, *Data* [, PARAMETER_NAME=*string*] [, /PRESERVE_LOCATION]

# Arguments

## Data

An object reference or array of object references to IDLitData objects to be added to the parameter set.

# Keywords

## PARAMETER_NAME

Set this keyword to a string or array of strings containing the names of parameters to be associated with the data objects. If this value is not provided, a null string (`''`) is associated with the data object. If the value of this keyword is an array with fewer elements than the array specified as the *Data* argument, null strings are associated with data objects for which no parameter name is specified.

## PRESERVE_LOCATION

Set this keyword to leave the PARENT property (of all data items specified by the *Data* argument) unchanged. Normally, when an item is added to a parameter set (or any data container), the item's PARENT property is changed to be the parameter set or data container object. This, in turn, changes the data item's identifier string, since the item's location in the iTools hierarchy has changed. (See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for details.) In many cases, it is desirable to leave the PARENT property unchanged when adding items to a parameter set.

## Version History

Introduced: 6.0

## See Also

IDLitParameterSet::Remove

# IDLitParameterSet::Cleanup

The IDLitParameterSet::Cleanup procedure method performs all cleanup on the parameter set object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitParameterSet::]Cleanup() (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitParameterSet::Copy

The IDLitParameterSet::Copy function method will return a copy of the parameter set and its contents. All items contained in the parameter set are copied when this method is called.

For individual data objects contained in the parameter set, the following values are *not* copied:

- Values of unregistered properties.
- Values of properties registered after the data object is created.
- Property attribute values.

**Note**

If an object has been added to a contained data object, only the object reference to the added object is copied.

## Syntax

*Result* = *Obj* -> [IDLitParameterSet::]Copy()

## Return Value

Returns an IDLitParameterSet object that is a copy of the parameter set object on which the method was called.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitParameterSet::Get

The IDLitParameterSet::Get function method is used to retrieve one or more IDLitData objects from the parameter set.

## Syntax

*Result* = *Obj* -> [IDLitParameterSet::]Get( [, /ALL] [, COUNT=*variable*] [, NAME=*variable*] [, POSITION=*integer*]

## Return Values

Returns an object reference or array of object references to the IDLitData objects specified, or returns -1 if the method fails.

## Arguments

None

## Keywords

### ALL

Set this keyword to return an array containing object references to all IDLitData items in the parameter set.

### COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

### NAME

Set this keyword equal to a named variable that will contain a string or string array of the parameter names associated with the returned IDLitData objects. If a returned data object has no parameter name, a null string ( '' ) is returned.

### POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the desired IDLitData objects within the parameter set.

## Version History

Introduced: 6.0

# IDLitParameterSet::GetByName

The IDLitParameterSet::GetByName function method returns the IDLitData object associated with a specified named parameter.

## Syntax

*Result* = *Obj* -> [IDLitParameterSet::]GetByName( *Names* [, COUNT=*variable*] [, NAME=*variable*] )

## Return Value

An object reference or array of object references to the IDLitData objects specified by the *Names* argument. If no matching parameter names are found, a null object is returned.

**Note**

If multiple parameter names are specified, the IDLitData objects are returned in the order in which they are stored in the IDLitParameterSet object, which is not necessarily the same as the order specified in the *Names* argument. Use the value returned by the NAME keyword to associate the parameter names with IDLitData objects in the returned array.

## Arguments

### Names

A scalar string or string array that contains the parameter names of the IDLitData objects to be retrieved from the parameter set.

**Note**

Parameter names can be supplied in any case; the search is case insensitive.

# Keywords

## NAME

Set this keyword equal to a named variable that will contain a scalar string or string array of the parameter names of the IDLitData objects returned by this method. When multiple parameter names are specified via the *Names* argument, the array returned in the NAME variable can be used to sort through the returned IDLitData objects by matching the indices of the two returned arrays.

## COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

# Version History

Introduced: 6.0

# IDLitParameterSet::GetParameterName

The IDLitParameterSet::GetParameterName function method retrieves the name of a specified parameter using a provided data object.

## Syntax

*Result* = *Obj* -> [IDLitParameterSet::]GetParameterName(*Data*, *Name*)

## Return Value

Returns an integer 1 if a parameter name was found for the specified IDLitData object, or 0 if no parameter name was found.

## Arguments

### Data

An IDLitData object for which the parameter name is being requested.

### Name

A named variable that will contain the parameter name associated with the object specified by the *oData* argument. If no parameter name is associated with the object specified by the *oData* argument, a null string (`''`) is returned.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitParameterSet::Init

The IDLitParameterSet::Init function method initializes the IDLitParameter object.

**Note**

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitParameterSet')

or

*Result* = *Obj* -> [IDLitParameterSet::]Init() (*Only in subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

## Arguments

None

## Keywords

The IDLitParameterSet object has no properties of its own, but inherits the properties of its superclass, IDLitDataContainer. Any property listed under "IDLitDataContainer Properties" on page 2798 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitParameterSet::Remove

The IDLitParameterSet::Remove procedure method is used to remove a data item from the parameter set.

## Syntax

*Obj* -> [IDLitParameterSet::]Remove [, *Items*] [, /ALL] [, POSITION=*integer*]

## Arguments

### Items

An object reference or array of object references to IDLitData objects to be removed from the parameter set.

## Keywords

### ALL

Set this keyword to remove all items from the parameter set. If this keyword is set, the *Items* parameter is not required.

### POSITION

Set this keyword equal to a scalar or array containing the zero-based indices within the parameter set of the specified IDLitData objects to be removed. If this keyword is set, the *Items* parameter is not required

## Version History

Introduced: 6.0

## See Also

IDLitParameterSet::Add

# IDLitReader

The IDLitReader class defines the interface used to construct file readers for the iTools framework. Objects of this class are not intended to be created as standalone entities; rather, this class should be included as the superclass of an iTool file reader class.

This class is written in the IDL language. Its source code can be found in the file `idlitreader__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitComponent

IDLitIMessaging

## Creation

See “IDLitReader::Init” on page 2962.

## Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- IDLitReader::Cleanup
- IDLitReader::GetData
- IDLitReader::GetFileExtensions
- IDLitReader::GetFilename
- IDLitReader::GetProperty
- IDLitReader::Init
- IDLitReader::IsA

- IDLitReader::SetFilename
- IDLitReader::SetProperty

In addition, this class inherits the methods of its superclasses.

## Examples

See Chapter 8, “Creating a File Reader” in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

# IDLitReader Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

# IDLitReader::Cleanup

The IDLitReader::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitReader::]Cleanup (*Only in subclass' Cleanup method.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitReader::GetData

The IDLitReader::GetData function method is called by the system to retrieve the data from the current file. When called, the reader should access the current filename and read the desired data. Once the information is loaded, the reader should place the obtained data in a data object, which is then passed back to the system.

This method will contain a majority of the implementation for a new reader class.

## Syntax

*Result* = *Obj* -> [IDLitReader::]GetData(*Data*)

## Return Value

Returns a 1 if successful, or a 0 if the initialization failed.

## Arguments

### Data

A data object that contains the read information. The reader determines the exact type and format of this data object, which keys off the type of information being read and what the format supports.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitReader::GetFileExtensions

The IDLitReader::GetFileExtensions function method is called by the system to retrieve the file extensions supported by this particular reader.

## Syntax

*Result* = *Obj* -> [IDLitReader::]GetFileExtensions([COUNT=*variable*])

## Return Value

Returns a scalar or string array that contains the file extensions associated with this reader.

## Arguments

None

## Keywords

### COUNT

Set this keyword equal to a named variable that will contain the number of items returned by this function.

## Version History

Introduced: 6.0

# IDLitReader::GetFilename

The IDLitReader::GetFilename function method is called by the system to retrieve the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then read at a later time. This method allows direct access to the file currently associated with the reader.

In addition, this methodology is helpful when multiple reads are performed from a given file.

## Syntax

*Result* = *Obj* -> [IDLitReader::]GetFilename()

## Return Value

Returns a string containing the current file name associated with this reader, or an empty string if no filename has been associated.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitReader::GetProperty

The IDLitReader::GetProperty procedure method retrieves the value of an IDLitReader property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

## Syntax

*Obj* -> [IDLitReader::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under "IDLitReader Properties" on page 2956 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitReader::Init

The IDLitReader::Init function method initializes the IDLitReader object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

# Syntax

*Obj* = OBJ_NEW('IDLitReader', *Extensions* [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLitReader::]Init(*Extensions* [, *PROPERTY=value*])

(*Only in subclass' Init method.*)

# Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

# Arguments

## Extensions

A scalar or string array containing the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (a correct value is "jpeg" not ".jpeg").

## Keywords

Any property listed under “IDLitReader Properties” on page 2956 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitReader::IsA

The IDLitReader::IsA function method is called by the system to determine if the given file is of the type supported by this file reader. Often this is used to determine what file reader to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new reader is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

## Syntax

*Result* = *Obj* -> [IDLitReader::]IsA(*Filename*)

## Return Value

Returns a 1 if the reader supports this type of file, or a 0 if the reader does not support this type of file.

## Arguments

### Filename

A string representing of the filename, which is used to check and determine if the reader supports its format.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitReader::SetFilename

The IDLitReader::SetFilename procedure method is called by the system to set the current filename associated with this reader. Due to the automated nature of the file reader system, filenames can be associated with a file reader and then the read at a later time.

## Syntax

*Obj* -> [IDLitReader::]SetFilename, *Filename*

## Arguments

### Filename

A string that contains the filename associated with this reader.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitReader::SetProperty

The IDLitReader::SetProperty procedure method sets the value of an IDLitReader property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

## Syntax

*Obj* -> [IDLitReader::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under "IDLitReader Properties" on page 2956 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitTool

The IDLitTool class represents all the functionality provided by a particular instance of an IDL Intelligent Tool. It provides the management systems for the underlying iTool functionality and implements the desired interfaces for external parties to interact with this functionality in a known manner.

This class is written in the IDL language. Its source code can be found in the file `idlittool__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Note on the IDLitToolbase Class

All iTools included with the IDL release are based on a subclass of the IDLitTool class named IDLitToolbase. If your aim is to create a new iTool that shares the common features of the iTools included with IDL, you should base your new iTool on the IDLitToolbase class. Since IDLitToolbase is a subclass of IDLitTool, it inherits all of IDLitTool's methods and properties. Additional features included in the IDLitToolbase class are described in "Subclassing from the IDLitToolbase Class" in Chapter 5 of the *iTool Developer's Guide* manual.

## Superclasses

IDLitContainer

IDLitIMessaging

## Creation

See "IDLitTool::Init" on page 2993.

## Properties

Objects of this class have the following properties. See "IDLitTool Properties" on page 2970 for details on individual properties.

- DESCRIPTION
- ICON
- NAME
- TYPE

- UPDATE_BYTYPE
- VERBOSE
- VERSION

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLitTool::Add
- IDLitTool::AddService
- IDLitTool::Cleanup
- IDLitTool::CommitActions
- IDLitTool::DisableUpdates
- IDLitTool::DoAction
- IDLitTool::DoSetProperty
- IDLitTool::DoUIService
- IDLitTool::EnableUpdates
- IDLitTool::GetCurrentManipulator
- IDLitTool::GetFileReader
- IDLitTool::GetFileWriter
- IDLitTool::GetManipulators
- IDLitTool::GetOperations
- IDLitTool::GetProperty
- IDLitTool::GetSelectedItems
- IDLitTool::GetService
- IDLitTool::GetVisualization
- IDLitTool::Init
- IDLitTool::RefreshCurrentWindow
- IDLitTool::Register
- IDLitTool::RegisterFileReader

- IDLitTool::RegisterFileWriter
- IDLitTool::RegisterManipulator
- IDLitTool::RegisterOperation
- IDLitTool::RegisterVisualization
- IDLitTool::SetProperty
- IDLitTool::UnRegister
- IDLitTool::UnRegisterFileReader
- IDLitTool::UnRegisterFileWriter
- IDLitTool::UnRegisterManipulator
- IDLitTool::UnRegisterOperation
- IDLitTool::UnRegisterVisualization

In addition, this class inherits the methods of its superclasses.

## Examples

See "Example: Simple iTool" in Chapter 5 of the *iTool Developer's Guide* manual.

## Version History

Introduced: 6.0

## See Also

Chapter 5, "Creating an iTool" in the *iTool Developer's Guide* manual

# IDLitTool Properties

IDLitTool objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLitTool::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be set via IDLitTool::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLitTool::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## DESCRIPTION

This property contains a string representing the full name or description of this object.

| | | | |
|---|---|---|---|
| **Property Type** | STRING | | |
| **Name String** | Description | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ICON

A string identifying the icon that should be used when displaying the iTool object. See “System Resources” in Chapter 2 of the *iTool Developer’s Guide* manual for additional details.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## NAME

A string representing the name of this object.

| | |
|---|---|
| **Property Type** | STRING |
| **Name String** | Name |

| | | | |
|---|---|---|---|
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TYPE

A string or vector of strings that identify the type(s) that this iTool represents.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## UPDATE_BYTYPE

A Boolean value controlling whether the given iTool will add new functionality to it as new visualization types are added. By default, when a new visualization is added to the iTool, any functionality associated with that visualization type is added to the iTool. If this property is set to zero (False), this updating is disabled.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## VERBOSE

A named variable that will control the verbose logging of the iTool. If set to a non-zero value, the iTool will log more information than normal. If this keyword is set to 0, minimal logging (error conditions only) will be sent to the logging system.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## VERSION

A named variable that will be set to the version of the iTool system.

| | |
|---|---|
| **Property Type** | String |
| **Name String** | *not displayed* |

| | | | |
|---|---|---|---|
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLitTool::Add

The IDLitTool::Add procedure method adds any item to the iTool. If called with a Visualization, that visualization is added to the current IDLitWindow object. If called with a data object, that data object is placed in the systems data manager. All other items are added to the iTool container.

## Syntax

*Obj* -> [IDLitTool::]Add, *Item*

## Arguments

### Item

The item to add to the iTool.

## Keywords

This method passes keywords to the Add method of the appropriate object. If the target destination is a data object, no keywords are passed. If the target destination is a visualization object, the keywords are passed to the IDLitWindow::Add method; otherwise, the keywords are passed to the IDLitContainer::Add method.

## Version History

Introduced: 6.0

# IDLitTool::AddService

The IDLitTool::AddService procedure method adds a service to the iTool. Unlike registration methodologies provided by the iTool, the method takes an existing object and adds it to the service repository in the iTool.

When a service is added to the system, a description of this service class is placed in the tools service folder. If it is desired to retrieve this descriptor at a later time, the iTool relative identifier would be `SERVICES/identifier`, where `identifier` is the identifier provided to this method.

## Syntax

*Obj* -> [IDLitTool::]AddService, *Service*

## Arguments

### Service

Set this variable to the service to add to the tools service repository. This service can be retrieved at a later point in time using its identifier (specified when creating the service object via the identifier keyword).

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::Cleanup

The IDLitTool::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitTool::]Cleanup (*Only in subclass' Cleanup method.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::CommitActions

The IDLitTool::CommitActions procedure method commits all pending transactions to the undo-redo buffer and causes a refresh of the current window.

This method is designed to be used in conjunction with the IDLitTool::DoSetProperty method.

## Syntax

*Obj* -> [IDLitTool::]CommitActions

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

## See Also

IDLitTool::DoSetProperty

# IDLitTool::DisableUpdates

The IDLitTool::DisableUpdates procedure method disables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates are re-enabled by calling the EnableUpdates method.

## Syntax

*Obj* -> [IDLitTool::]DisableUpdates

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::DoAction

The IDLitTool::DoAction function method initiates an operation or action in the iTool object. The identifier that is passed in as the argument to this method specifies the action that executes.

## Syntax

*Result* = *Obj* -> [IDLitTool::]DoAction(*Identifier*)

## Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

## Arguments

### Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation that it implements.

## Keywords

All keywords are passed to the DoAction function of the object in the iTool that performs the operation.

## Version History

Introduced: 6.0

# IDLitTool::DoSetProperty

The IDLitTool::DoSetProperty function method sets a property on a target component object, and places the change in the undo/redo transaction buffer.

**Note**

In order to commit the change to the undo/redo transaction buffer, you must call the IDLitTool::CommitActions method. The property change is not actually undoable until it has been committed.

The separation of addition of the change to the buffer and commit of the change allows you to "package" several property changes into a single undo/redo transaction. The call to the CommitActions method will commit any changes that have been performed but not committed. For example, the following statements change two properties on an iTool component (`oTarget`) and commit them together:

```
targetID = oTarget -> GetFullIdentifier()
status = oTool -> DoSetProperty(targetID, 'Property1', 'Value 1')
status = oTool -> DoSetProperty(targetID, 'Property2', 'Value 2')
oTool -> CommitActions
```

If the user later undoes the action, both property value changes will be reversed in one step.

## Syntax

*Result* = *Obj* -> [IDLitTool::]DoSetProperty(*TargetIdentifier*, *PropertyIdentifier*, *Value*)

## Return Value

Returns 1 if the SetProperty was successful, or 0 otherwise.

**Note**

If successful, you are responsible for calling IDLitTool::CommitActions to complete the transaction.

# Arguments

## TargetIdentifier

A scalar string or a string array containing the full object identifiers of the objects on which the property is being set.

## PropertyIdentifier

A scalar string containing the property identifier to change. *PropertyIdentifier* must be a registered property of the target objects.

## Value

The new property value.

# Keywords

None

# Version History

Introduced: 6.0

# See Also

IDLitTool::CommitActions

# IDLitTool::DoUIService

The IDLitTool::DoUIService function method initiates a request for a UI service to execute. This method allows underlying iTool functionality to perform user-interface interactions without having a direct connection to the user interface portion of the iTool.

An example of an iTool UI service would be the **File → Open** command, which will prompt the user to select a file using the standard file open dialog. This command is identified by setting the *ServiceIdentifier* argument to `FileOpen`. See Chapter 12, "Creating a User Interface Service" in the *iTool Developer's Guide* manual for more information about UI services.

## Syntax

*Result* = *Obj* -> [IDLitTool::]DoUIService(*ServiceIdentifier*, *Requestor*)

## Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

## Arguments

### ServiceIdentifier

A string identifier that specifies the UI service being requested. This identifier is passed to the tools user interface for control dispatching purposes.

### Requestor

An object reference to the object that is requesting the UI service. The UI service uses this object to obtain any information particular to the interaction taking place.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::EnableUpdates

The IDLitTool::EnableUpdates procedure method re-enables all drawing updates to the current window and UI updates (menu sensitivity) being passed to the user interface. After this method is called, updates can be disabled by calling the DisableUpdates method.

## Syntax

*Obj* -> [IDLitTool]::EnableUpdates

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::GetCurrentManipulator

The IDLitTool::GetCurrentManipulator function method returns the current manipulator in the system.

## Syntax

*Result* = *Obj* -> [IDLitTool]::GetCurrentManipulator()

## Return Value

Returns an object reference to the current manipulator.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::GetFileReader

The IDLitTool::GetFileReader function method retrieves a file reader registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

## Syntax

*Result* = *Obj* -> [IDLitTool::]GetFileReaders(*Identifier* [, /ALL] [, COUNT=*variable*])

## Return Value

Returns the object descriptors constructed for the registered file reader.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file readers registered with the system.

## Arguments

### Idenitifer

A string representing the single level identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

## Keywords

### ALL

Set this keyword to return all file readers registered with the iTool and the system.

### COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

## Version History

Introduced: 6.0

# IDLitTool::GetFileWriter

The IDLitTool::GetFileWriter function method retrieves a file writer registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

## Syntax

*Result* = *Obj* -> [IDLitTool::]GetFileWriters(*Identifier* [, /ALL] [, COUNT=*variable*])

## Return Value

Returns the object descriptors constructed for the registered file writer.

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool and those file writers registered with the system.

## Arguments

### Identifier

A string representing the identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call.

## Keywords

### ALL

Set this keyword to return all file writers registered with the iTool and the system.

### COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

## Version History

Introduced: 6.0

# IDLitTool::GetManipulators

The IDLitTool::GetManipulators function method retrieves the manipulators registered with the iTool object. Unlike other items in the iTool and due to the active nature of the subsystem, manipulators are instantiated when registered.

## Syntax

*Result* = *Obj* -> [IDLitTool::]GetManipulators([COUNT=*variable*])

## Return Value

Returns the object references to the manipulators that were instantiated when items were registered with the iTool.

## Arguments

None

## Keywords

### COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

## Version History

Introduced: 6.0

# IDLitTool::GetOperations

The IDLitTool::GetOperations function method retrieves the operations registered with the iTool object.

**Note**

This routine returns a set of object descriptor classes that reference the items registered with the iTool. In addition, if the operation folder in the registry contains sub-folders, the returned list will contain IDLitContainer classes, each containing sub-operations.

## Syntax

*Result* = *Obj* -> [IDLitTool::]GetOperations([, IDENTIFIER=*string*] [, COUNT=*variable*])

## Return Value

Returns the object descriptors constructed for the registered operations.

## Arguments

None

## Keywords

### IDENTIFIER

Set this keyword to an optional identifier that identifies the location in the operation hierarchy to retrieve the operation object descriptors from.

### COUNT

Set this keyword to a named variable that will contain the number of object descriptors returned by this method.

## Version History

Introduced: 6.0

# IDLitTool::GetProperty

The IDLitTool::GetProperty procedure method retrieves the value of an IDLitTool property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

## Syntax

*Obj* -> [IDLitTool::]GetProperty, [*PROPERTY=variable]*

## Arguments

None

## Keywords

Any property listed under "IDLitTool Properties" on page 2970 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitTool::GetSelectedItems

The IDLitTool::GetSelectedItems function method returns a vector of references to the objects currently selected within the current window in the iTool. If no objects are currently selected, this function returns `-1`.

## Syntax

*Result* = *Obj* -> [IDLitTool::]GetSelectedItems([COUNT=*variable*])

## Return Value

Returns a vector of references to the currently selected objects. If no objects are currently selected, this function returns `-1`.

## Arguments

None

## Keywords

### COUNT

Set this keyword to a named variable that will contain the number of valid items returned by this function.

## Version History

Introduced: 6.0

# IDLitTool::GetService

The IDLitTool::GetService method retrieves a service that has been registered with the iTool.

## Syntax

*Result* = *Obj* -> [IDLitTool::]GetService(*IdService*)

## Return Value

Returns an object reference to the service.

## Arguments

### IdService

The identifier of the desired service.

**Note**

*IdService* should specify only the relative identifier, not the fully-qualified identifier. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for details.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::GetVisualization

The IDLitTool::GetVisualization function method retrieves a visualization registered with the iTool object. If the requested item does not exist in the given iTool, the system will be queried to see if it supports an object of the given identifier.

## Syntax

*Result* = *Obj* -> [IDLitTool::]GetVisualizations(*Identifier* [, /ALL] [, COUNT=*variable*])

## Return Value

Returns the object descriptors constructed for the registered visualizations. (See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object descriptors.)

If the ALL keyword is set, the *Identifier* argument is ignored and the resulting list of object descriptors will be both those registered with the specific iTool as well as those visualizations registered with the system.

## Arguments

### Identifier

A string containing the relative identifier of the item that is being requested. This identifier is the value provided during object registration and is either supplied using the IDENTIFIER keyword during registration, or constructed automatically by the name that is provided during the registration call. (See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of relative vs. fully-qualified identifiers.)

## Keywords

### ALL

Set this keyword to return all visualizations registered with the iTool and the system.

### COUNT

Set this keyword to a variable that will contain the number of object descriptors returned by this method. (See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object descriptors.)

## Version History

Introduced: 6.0

# IDLitTool::Init

The IDLitTool::Init function method initializes the IDLitTool object, and should be called by the Init method of a subclass.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitTool'[, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLitTool::]Init([*PROPERTY*=*value*])
(*Only in a subclass' Init method.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLitTool Properties" on page 2970 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitTool::RefreshCurrentWindow

The IDLitTool::RefreshCurrentWindow procedure method redraws the current window of the iTool. The redraw will occur only if updates are enabled in the iTool.

## Syntax

*Obj* -> [IDLitTool]::RefreshCurrentWindow

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::Register

The IDLitTool::Register procedure method registers a generic object subclassed from the IDLitComponent class with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed. Unlike the other provided methods to register components, this method is generic.

This method allows items to be registered in the standard registry folders of the IDLitTool object, and can be used as well for the creation of new folders. If the provided identifier specifies a folder that does not currently exist in the iTool, it is created.

This method performs none of the validation performed by the specific registration functions. As such, it can cause issues with iTool operation, if used incorrectly. You should use the following related methods for registering certain, specific components to insure validation:

- File readers — “IDLitTool::RegisterFileReader” on page 2999.
- File writers — “IDLitTool::RegisterFileWriter” on page 3001.
- Manipulators — “IDLitTool::RegisterManipulator” on page 3003.
- Operations — “IDLitTool::RegisterOperation” on page 3005.
- Visualizations — “IDLitTool::RegisterVisualization” on page 3007

# Syntax

*Obj* -> [IDLitTool::]Register, *Name*, *ClassName* [, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*] [, PROXY=*string*]

# Arguments

## Name

A string containing the human readable name of the component type being registered with the iTool.

## ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

# Keywords

**Note**

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

## DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

## ICON

Set this keyword to the icon that should be used when displaying the iTool object. See "System Resources" in Chapter 2 of the *iTool Developer's Guide* manual for additional details.

## IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

To use one of the iTool-provided registration locations, the value of this keyword should contain the destination for the new component that is being registered. Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

## PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed to this item are routed to the item specified by the identifier provide to this keyword. (See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object descriptors.)

## Version History

Introduced: 6.0

# IDLitTool::RegisterFileReader

The IDLitTool::RegisterFileReader procedure method registers a file reader component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a reader class is registered with the system, an object descriptor for this operation class is placed in the iTool's file reader folder. To retrieve this descriptor at a later time, the iTool relative identifier would be `FILE READERS/identifier`, where `identifier` is the identifier provided to this method.

## Syntax

*Obj* -> [IDLitTool::]RegisterFileReader, *Name*, *ClassName*
[, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*]
[, PROXY=*string*]

## Arguments

### Name

The human readable name of the component type being registered with the iTool.

### ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

## Keywords

**Note**

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

### DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

### ICON

Set this keyword to the icon that should be used when displaying the file reader in an iTool browser. See "System Resources" in Chapter 2 of the *iTool Developer's Guide* manual for additional details.

### IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file reader registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

### PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object descriptors.)

## Version History

Introduced: 6.0

# IDLitTool::RegisterFileWriter

The IDLitTool::RegisterFileWriter procedure method registers a file writer component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a writer class is registered with the system, an object descriptor for this operation class is placed in the iTool's file writer folder. To retrieve this descriptor at a later time, the iTool relative identifier would be `FILE WRITERS/identifier`, where `identifier` is the identifier provided to this method.

# Syntax

*Obj* -> [IDLitTool::]RegisterFileWriter, *Name*, *ClassName*
[, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*]
[, PROXY=*string*]

# Arguments

## Name

A string containing the human readable name of the component type being registered with the iTool.

## ClassName

A string containing the class name of the component being registered. The iTool object uses this class name to instantiate a component of this type when requested by the system.

# Keywords

**Note**

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

## DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

### ICON

Set this keyword to the icon that should be used when displaying the file writer in an iTool browser. See "System Resources" in Chapter 2 of the *iTool Developer's Guide* manual for additional details.

### IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided *Name* value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the file writer registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

### PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object descriptors.)

## Version History

Introduced: 6.0

# IDLitTool::RegisterManipulator

The IDLitTool::RegisterManipulator procedure method registers a manipulator component with the iTool. Once registered, the iTool has the ability to instantiate this type of component when needed.

When a manipulator class is registered with the system, an object of the given class is created and added to the tools manipulator manager (an instance of IDLitManipulatorManager). To reference the new manipulator, the identifier that is provided should be prepended with the MANIPULATORS identifier level.

## Syntax

*Obj* -> [IDLitTool::]Manipulator, *Name*, *ClassName* [, /DEFAULT] [, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*]

## Arguments

### Name

A string containing the human readable name of the component type being registered with the iTool.

### ClassName

A string containing the class name of the component being registered. This class name is used by the iTool object to instantiate a component of this type when requested by the system.

## Keywords

**Note**

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

### DEFAULT

If set, this registered item will be treated as the default manipulator for this iTool. Only one default manipulator can exist at anytime.

### DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

### ICON

Set this keyword to the icon that should be used when displaying the manipulator in an iTool menubar. See "System Resources" in Chapter 2 of the *iTool Developer's Guide* manual for additional details.

### IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

## Version History

Introduced: 6.0

# IDLitTool::RegisterOperation

The IDLitTool::RegisterOperation procedure method registers an operation component with the iTool. Once registered, the iTool has the ability to instantiate this type of operation when needed.

When an operation class is registered with the system, an object descriptor for this operation class is placed in the tools operations folder. To retrieve this descriptor at a later time, the iTool relative identifier would be `OPERATIONS/identifier,` where `identifier` is the identifier provided to this method.

# Syntax

*Obj* -> [IDLitTool::]RegisterOperation, *Name*, *ClassName* [, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*] [, PROXY=*string*]

# Arguments

## Name

A string containing the human readable name of the operation type being registered with the iTool. If the name includes leading identifier values that indicates a location in the operation hierarchy of the iTool, the new operation shall be placed in the target location.

If the target location specified by the name does not exist in the tools operation hierarchy, it is created.

## ClassName

A string containing the class name of the operation component being registered. This class name is used by the iTool object to instantiate an operation component of this type when requested.

# Keywords

**Note**

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

### DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

### ICON

Set this keyword to the icon that should be used when displaying the operation in an iTool browser. See "System Resources" in Chapter 2 of the *iTool Developer's Guide* manual for additional details.

### IDENTIFIER

Set this keyword to the identifier that should be used by the system for this component type. If not provided, an identifier is constructed from the provided name value.

If a multiple level identifier is provided (indicated by the presence of a "/"), the registered item is placed in a subfolder of the tools operation folder. If the specified folder is not present in the iTool at registration time, it is created. It is this functionality that allows operations to be classified in logical groupings and results in sub-menu items in the operations menus of the iTool interface.

### PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword. (See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of object descriptors.)

## Version History

Introduced: 6.0

# IDLitTool::RegisterVisualization

The IDLitTool::RegisterVisualization procedure method registers a visualization component with the iTool. Once registered, the iTool has the ability to instantiate this type of visualization when needed.

When a visualization class is registered with the system, an object descriptor for this visualization class is placed in the iTool's visualization folder. To retrieve this descriptor at a later time, the iTool relative identifier would be: `VISUALIZATIONS/identifier` where identifier is the identifier provided to this method.

## Syntax

*Obj* -> [IDLitTool::]RegisterVisualization, *Name*, *ClassName* [, /DEFAULT] [, DESCRIPTION=*string*] [, ICON=*string*] [, IDENTIFIER=*string*] [, PROXY=*string*]

## Arguments

### Name

A string containing the human readable name of the visualization type being registered with the iTool.

### ClassName

A string containing the class name of the visualization component being registered. The iTool object uses this class name to instantiate a visualization component of this type when requested.

## Keywords

**Note**

Any keywords provided to this routine but not listed here are treated as property defaults for the registered item and applied to the registered object when it is created.

### DEFAULT

If set, this registered item will be treated as the default visualization for this iTool. Only one default visualization can exist at a time.

### DESCRIPTION

Set this keyword to a string that provides a brief description of the component being registered.

### ICON

Set this keyword to the icon that should be used when displaying the visualization in an iTool browser. See "System Resources" in Chapter 2 of the *iTool Developer's Guide* manual for additional details.

### IDENTIFIER

Set this keyword to the identifier that should be used by the system for this visualization type. If not provided, an identifier is constructed from the provided name value.

While some items registered with an iTool can contain sub-folders that are specified by identifiers, the visualization registration cannot. As such, any nested identifiers that are registered are not visible to the iTool system.

### PROXY

Set this keyword to the identifier of the object that this registered item should utilize instead of providing a new object descriptor. If a proxy is registered, all requests and actions performed on this item are routed to the item specified by the identifier provided for this keyword.

## Version History

Introduced: 6.0

# IDLitTool::SetProperty

The IDLitTool::SetProperty procedure method sets the value of an IDLitTool property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

## Syntax

*Obj* -> [IDLitTool::]SetProperty[, *PROPERTY=value]*

## Arguments

None

## Keywords

Any property listed under "IDLitTool Properties" on page 2970 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

## See Also

IDLitTool::DoSetProperty

# IDLitTool::UnRegister

The IDLitTool::UnRegister procedure method unregisters a component with the iTool. When a component is unregistered, it is no longer available to perform whatever function it performs, and it is removed from iTool menus and toolbars.

# Syntax

*Obj* -> [IDLitTool::]UnRegister, *Identifier*

# Arguments

## Identifier

Set this to the relative identifier of the component to be removed from the iTool. To remove a component from the standard folders in the iTool's content registry, this identifier should contain the location of the component as well as the component identifier itself. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of iTool identifiers.

Valid destinations in the iTool are:

- Visualizations
- Operations
- Manipulators
- File Writers
- File Readers

# Keywords

None

# Version History

Introduced: 6.0

# IDLitTool::UnRegisterFileReader

The IDLitTool::UnRegisterFileReader procedure method unregisters a file reader component with the iTool. When a file reader is unregistered, it is no longer available to import files into the iTool, and it is removed from iTool menus and toolbars.

## Syntax

*Obj* -> [IDLitTool::]UnRegisterFileReader, *Identifier*

## Arguments

### Identifier

Set this to the relative identifier of the file reader to be removed from the iTool. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of iTool identifiers.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::UnRegisterFileWriter

The IDLitTool::UnRegisterFileWriter procedure method unregisters a component with the iTool. When a file writer is unregistered, it is no longer available to export files from the iTool, and it is removed from iTool menus and toolbars.

## Syntax

*Obj* -> [IDLitTool::]UnRegisterFileWriter, *Identifier*

## Arguments

### Identifier

Set this to the relative identifier of the file writer to be removed from the iTool. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of iTool identifiers.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::UnRegisterManipulator

The IDLitTool::UnRegisterManipulator procedure method unregisters a manipulator component with the iTool. When a manipulator is unregistered, it is removed from iTool menus and toolbars.

## Syntax

*Obj* -> [IDLitTool::]UnRegisterManipulator, *Identifier*

## Arguments

### Identifier

Set this to the relative identifier of the manipulator to be removed from the iTool. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of iTool identifiers.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::UnRegisterOperation

The IDLitTool::UnRegisterOperation procedure method unregisters an operation component with the iTool. When an operation is unregistered, it is no longer available to perform actions within the iTool, and it is removed from iTool menus and toolbars.

## Syntax

*Obj* -> [IDLitTool::]UnRegisterOperation, *Identifier*

## Arguments

### Identifier

Set this to the relative identifier of the component to be removed from the iTool. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of iTool identifiers.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitTool::UnRegisterVisualization

The IDLitTool::UnRegisterVisualization procedure method unregisters a visualization component with the iTool. When a visualization is unregistered, visualizations of its type can no longer be created by the iTool, and it is removed from iTool menus and toolbars.

## Syntax

*Obj* -> [IDLitTool::]UnRegisterVisualization, *Identifier*

## Arguments

### Identifier

Set this to the relative identifier of the visualization to remove from the iTool. See "iTool Object Identifiers" in Chapter 2 of the *iTool Developer's Guide* manual for a discussion of iTool identifiers.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitUI

The IDLitUI class serves as the link between the underlying functionality of an iTool and the IDL Widget interface that is displayed to the user. The user interface object provides the following functionality:

- Access to and communication with the underlying iTool object.
- Registration of various user interface elements that are part of the iTool.
- Registration and management of dialog sub-elements that are used by the iTool to perform specific tasks.

For additional information on the IDLitUI class, and user interface issues in general, see Chapter 10, "iTool User Interface Architecture" in the *iTool Developer's Guide* manual.

This class is written in the IDL language. Its source code can be found in the file `idlitui__define.pro` in the `lib/itools/ui_widgets` subdirectory of the IDL distribution.

## Superclasses

IDLitContainer

## Creation

See "IDLitUI::Init" on page 3026.

## Properties

Objects of this class have the following properties. See "IDLitUI Properties" on page 3018 for details on individual properties.

- GROUP_LEADER

## Methods

This class has the following methods:

- IDLitUI::AddOnNotifyObserver
- IDLitUI::Cleanup
- IDLitUI::DoAction

- IDLitUI::GetProperty
- IDLitUI::GetTool
- IDLitUI::GetWidgetByName
- IDLitUI::Init
- IDLitUI::RegisterUIService
- IDLitUI::RegisterWidget
- IDLitUI::RemoveOnNotifyObserver
- IDLitUI::SetProperty
- IDLitUI::UnRegisterUIService
- IDLitUI::UnRegisterWidget

In addition, this class inherits the methods of its superclasses (if any).

## Examples

See "Example: A Simple UI Panel" in Chapter 13 of the *iTool Developer's Guide* manual.

## Version History

Introduced: 6.0

## See Also

Chapter 10, "iTool User Interface Architecture" in the *iTool Developer's Guide* manual

# IDLitUI Properties

IDLitUI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLitUI::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be set via IDLitUI::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLitUI::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## GROUP_LEADER

A long integer containing the IDL Widget ID of the group leader widget for the user interface.

| | | | |
|---|---|---|---|
| **Property Type** | Long Integer (Widget ID) | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLitUI::AddOnNotifyObserver

The IDLitUI::AddOnNotifyObserver procedure method is used to register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object.

## Syntax

*Obj* -> [IDLitUI::]AddOnNotifyObserver, *IdObserver*, *IdSubject*

## Arguments

### IdObserver

The object identifier of an iTool component object that is the *observer* expressing interest in the subject specified by *IdSubject*. Often, *IdObserver* is the object identifier of the object on which this method is being called.

The object specified by *IdObserver* must implement the OnNotify callback method, which is called when a notification message is dispatched to *IdObserver* by the DoOnNotify method of another iTool component object (usually the object specified by *IdSubject*). The OnNotify method has the following signature:

```
PRO ::OnNotify, idObject, idMessage, message
```

where

- *idObject* is the object identifier of the iTool component that is the source of the message.
- *idMessage* is a string that identifies the type of message being sent.
- *message* is the message data itself.

In general, the *idMessage* string is used by the OnNotify method to determine what type of action to take. See “IDLitIMessaging::DoOnNotify” on page 2828 for additional details.

### IdSubject

A string identifying the item that *IdObserver* is interested in. This is normally the object identifier of a particular iTool component object, but it can be any string value. When a message sent via IDLitIMessaging::DoOnNotify specifies *IdSubject* as the originator, the *IdObserver* object’s OnNotify method is called.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitUI::Cleanup

The IDLitUI::Cleanup procedure method performs all cleanup on the object, and should be called by the Cleanup method of a subclass.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitUI::]Cleanup (only in subclass' *Cleanup* method)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitUI::DoAction

The IDLitUI::DoAction function method initiates an operation or action in the iTool object associated with this user interface. The identifier that is passed in as the argument to this method specifies the action that executes.

## Syntax

*Result* = *Obj* -> [IDLitUI::]doAction(*Identifier*)

## Return Value

Returns 1 if the action succeeds, or 0 if the action fails.

## Arguments

### Identifier

This argument is set to a string identifier that specifies the object in the iTool that performs the operation or action that it implements.

## Keywords

All keywords are passed to the DoAction function of the object in the iTool that performs the operation or action.

## Version History

Introduced: 6.0

# IDLitUI::GetProperty

The IDLitUI::GetProperty procedure method retrieves the value of an IDLitUI property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

## Syntax

*Obj* -> [IDLitUI::]GetProperty, [*PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under "IDLitUI Properties" on page 3018 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitUI::GetTool

The IDLitUI::GetTool function method returns an object reference to the iTool with which the user interface is associated.

## Syntax

*Result* = *Obj* -> [IDLitUI::]GetTool()

## Return Value

Returns an object reference to the iTool associated with the current user interface, or a null object if there is no associated iTool.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitUI::GetWidgetByName

The IDLitUI::GetWidgetByName function method returns the IDL Widget ID of a widget that has been registered with the user interface object via a call to the IDLitUI::RegisterWidget method.

## Syntax

*Result* = *Obj* -> [IDLitUI::]GetWidgetByName(*Name*)

## Return Value

Returns the widget identifier (a long integer) of the widget specified by the Name argument, or 0 if the widget was not registered with the iTool system.

## Arguments

### Name

Set this argument to the name that the desired widget was registered with.

## Keywords

None

## Example

This method can be used to determine whether a given widget already exists and act accordingly. For example, the following code checks to determine whether a widget registered as `myWidget` exists; if it does, that widget is mapped and un-iconified:

```
wID = oUI -> GetWidgetByName(myWidget)
IF(wID NE 0) THEN BEGIN
   WIDGET_CONTROL, wID, /MAP, ICONIFY=0 ;; show the widget
   RETURN
ENDIF
```

Similar code is used in many of the widget interface elements used by the standard iTools included with IDL.

## Version History

Introduced: 6.0

# IDLitUI::Init

The IDLitUI::Init function method initializes the IDLitUI object, and should be called by the Init method of a subclass.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitUI')

or

*Result* = *Obj* -> [IDLitUI::]Init() (*Only in subclass' Init method.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitUI::RegisterUIService

The IDLitUI::RegisterUIService function method registers a *user interface service* with the user interface. Once the user interface service has been registered, the iTool with which the user interface is associated can call the UI service to display dialogs or other UI elements.

**Note**

Every UI service must implement a callback function that displays the requested user interface. See Chapter 12, "Creating a User Interface Service" in the *iTool Developer's Guide* manual for details.

## Syntax

*Restult* = *Obj* -> [IDLitUI::]RegisterUIService(*Name, Callback*)

## Return Value

Returns an iTool object identifier for the UI service specified by *Name*.

## Arguments

### Name

A string containing the human readable name of the user interface being registered.

### Callback

A string containing the name of the callback function for this UI service. The callback function is called when execution of the UI service is requested. The callback should have the following calling signature:

```
FUNCTION NAME, oUI, oTarget
```

where:

- *NAME* is the name of the callback function,
- *oUI* is an object reference to the user interface object of which the UI service is a part
- *oTarget* is an object reference to the object that is the target of the operation or action with which the UI service is associated.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitUI::RegisterWidget

The IDLitUI::RegisterWidget function method registers an IDL widget hierarchy with the user interface object. Once a widget has been registered with the UI object, the UI can route messages to that widget and manage visibility if the widget is registered with the FLOATING property set.

## Syntax

*Result* = *Obj* -> [IDLitUI::]RegisterWidget(*wID*, *Name*, *Callback*[, /FLOATING])

## Return Value

The iTool object identifier of the user interface adaptor that links the widget specified by *wID* with the iTool.

## Arguments

### wID

A long integer containing the widget ID of the widget being registered. This value is provided to the routine specified by the *Callback* argument when it is called.

### Name

A string containing the human readable name for the widget being registered.

### Callback

A string containing the name of a *callback procedure* for the widget. Any notification messages sent by the iTool to this widget are sent to this callback procedure. The callback procedure should have the following calling signature:

```
PRO NAME, wID, strID, message, messageData
```

where:

- *NAME* is the name of the callback procedure,
- *wID* is the widget ID provided to the IDLitUI:;RegisterWidget method,
- *strID* is a string containing the object identifier of the iTool object that triggered the message,

- *message* is the message being sent to the callback procedure,
- *messageData* is any data associated with the message.

**Note**

If this argument is set to an empty string, no callbacks will be made to this widget.

# Keywords

## FLOATING

Set this keyword to treat the widget as a floating element of the specified iTool user interface, to be managed by the user interface object. If this keyword is set, the widget will only be visible if the associated iTool is “current,” and the widget will be destroyed when the iTool is destroyed.

# Version History

Introduced: 6.0

# IDLitUI::RemoveOnNotifyObserver

The IDLitUI::RemoveOnNotifyObserver procedure method is used to un-register a specified iTool component object as wishing to receive messages generated by the DoOnNotify method of another specified iTool component object. This method reverses the action of calling the IDLitUI::AddOnNotifyObserver method.

## Syntax

*Obj* -> [IDLitUI::]RemoveOnNotifyObserver, *IdObserver*, *IdSubject*

## Arguments

### IdObserver

The object identifier of an iTool component object that is currently registered as an observer of the component specified by *IdSubject*. Often, this is the object identifier of the object on which method is being called.

### IdSubject

The object identifier of the iTool component object that *IdObserver* is currently registered as observing. This is normally the object identifier of a particular iTool component object, but it can also be a string that references a global system service.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitUI::SetProperty

The IDLitUI::SetProperty procedure method sets the value of an IDLitUI property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

## Syntax

*Obj* -> [IDLitUI::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitUI::UnRegisterUIService

The IDLitUI::UnRegisterUIService procedure method unregisters a user interface service with the user interface object.

## Syntax

*Obj* -> [IDLitUI::]UnRegisterUIService, *Name*

## Arguments

### Name

A string containing the name of the UI service to be unregistered.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitUI::UnRegisterWidget

The IDLitUI::UnRegisterWidget procedure method unregisters a widget with the user interface object.

## Syntax

*Obj* -> [IDLitUI::]UnRegisterWidget, *Name*

## Arguments

### Name

A string containing the name of the widget to be unregistered.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization

The IDLitVisualization class represents the base visualization component, from which all iTool visualization classes should subclass. IDLitVisualization acts as a container and provides methods for adding, removing, and grouping visualization components.

This class is written in the IDL language. Its source code can be found in the file `idlitvisualization__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLgrModel

IDLitIMessaging

IDLitParameter

## Creation

See "IDLitVisualization::Init" on page 3059.

## Properties

Objects of this class have the following properties. See "IDLitVisualization Properties" on page 3038 for details on individual properties.

- CENTER_OF_ROTATION
- GROUP_PARENT
- IMPACTS_RANGE
- ISOTROPIC
- MANIPULATOR_TARGET
- TYPE

In addition, objects of this class inherit the properties of all superclasses of this class.

# Methods

This class has all the methods associated with the superclasses, plus the following methods:

- IDLitVisualization::Add
- IDLitVisualization::Aggregate
- IDLitVisualization::Cleanup
- IDLitVisualization::Get
- IDLitVisualization::GetCenterRotation
- IDLitVisualization::GetCurrentSelectionVisual
- IDLitVisualization::GetDataSpace
- IDLitVisualization::GetDataString
- IDLitVisualization::GetDefaultSelectionVisual
- IDLitVisualization::GetManipulatorTarget
- IDLitVisualization::GetProperty
- IDLitVisualization::GetSelectionVisual
- IDLitVisualization::GetTypes
- IDLitVisualization::GetXYZRange
- IDLitVisualization::Init
- IDLitVisualization::Is3D
- IDLitVisualization::IsIsotropic
- IDLitVisualization::IsManipulatorTarget
- IDLitVisualization::IsSelected
- IDLitVisualization::OnDataChange
- IDLitVisualization::OnDataComplete
- IDLitVisualization::OnDataRangeChange
- IDLitVisualization::Remove
- IDLitVisualization::Scale
- IDLitVisualization::Select

- IDLitVisualization::Set3D
- IDLitVisualization::SetCurrentSelectionVisual
- IDLitVisualization::SetData
- IDLitVisualization::SetDefaultSelectionVisual
- IDLitVisualization::SetParameterSet
- IDLitVisualization::SetProperty
- IDLitVisualization::UpdateSelectionVisual
- IDLitVisualization::VisToWindow
- IDLitVisualization::WindowToVis

In addition, this class inherits the methods of its superclasses.

## Examples

See Chapter 6, “Creating a Visualization” in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

# IDLitVisualization Properties

IDLitVisualization objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLitVisualization::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be initialized via IDLitVisualization::Init. Properties with the word “Yes” in the “Set” column of the property table can be set via IDLitVisualization::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## CENTER_OF_ROTATION

A two- or three-element vector, [*x*, *y*] or [*x*, *y*, *z*] indicating the center (in data coordinates) of rotation for this visualization. If a two-element vector is supplied, the *z* value remains unchanged. When retrieving the value of this property, the center of rotation is always returned as a three-element vector.

| **Property Type** | Vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GROUP_PARENT

A reference to the IDLitVisualization object that serves as the group parent for this visualization.

| **Property Type** | Object Reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## IMPACTS_RANGE

A boolean that, when set to 0, indicates that the *x*, *y*, and *z* range of the contents of this visualization should not impact the *x*, *y*, and *z* range of any visualization that contains it. By default, IMPACTS_RANGE is 1.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | Init: Yes | **Registered:** No |

## ISOTROPIC

A boolean that, when set to a non-zero value, indicates that this object should have isotropic scaling applied to it. By default, ISOTROPIC is 0 (isotropic scaling is not enforced).

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## MANIPULATOR_TARGET

A boolean that, when set to a non-zero value, indicates that this object should be treated as a target for manipulations. By default, MANIPULATOR_TARGET is 0 (this object is not a target for manipulations).

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PROPERTY_INTERSECTION

A boolean value that indicates whether the visualization should display the intersection or the union of the properties of any aggregated objects. Visualizations that display the union of their aggregated objects' properties appear in iTool browsers as a single visualization with one set of properties. Visualizations that display the intersection of their aggregated objects' properties appear in iTool browsers as a container for the aggregated objects, allowing access to the contained objects'

properties as well as to those of the container. See "Working with Aggregated Properties" in Chapter 4 of the *iTool Developer's Guide* manual for additional discussion of aggregated properties.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *no default value* | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** No |

## TYPE

A string or vector of strings that identify the type(s) that this visualization represents. See "Predefined iTool Visualization Classes" in Chapter 6 of the *iTool Developer's Guide* manual for a list of predefined types.

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLitVisualization::Add

The IDLitVisualization::Add procedure method adds objects to the visualization container.

## Syntax

*Obj* -> [IDLitVisualization::]Add, *Objects* [, /AGGREGATE] [, /GROUP] [, /NO_UPDATE] [, POSITION=*index*]

## Arguments

### Objects

An object reference (or array of object references), each referring to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be added to the visualization container.

## Keywords

### AGGREGATE

Set this keyword to indicate that the object(s) being added should become part of this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (accessible via the GetProperty and SetProperty methods).

### GROUP

Set this keyword to indicate that the added object is to be considered part of the group that is rooted at this visualization. By default, the added objects are not considered to be part of the group.

### NO_UPDATE

Set this keyword to indicate that the overall scene should not be updated after the addition of the object(s). By default, the overall scene is updated.

### POSITION

Set this keyword equal to a scalar or vector of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within this visualization container at which the corresponding object should be placed. The default is to add new objects at the end of the list of contained items.

## Version History

Introduced: 6.0

# IDLitVisualization::Aggregate

The IDLitVisualization::Aggregate procedure method adds the given object(s) to this visualization's property aggregate. The properties of all aggregated objects are exposed as properties of this visualization (via ::GetProperty and ::SetProperty).

## Syntax

*Obj* -> [IDLitVisualization::]Aggregate, *Objects*

## Arguments

### Objects

An object reference (or array of object references), each of which refers to an atomic graphic object, an IDLgrModel, or another IDLitVisualization object to be aggregated within this visualization container.

## Keywords

None.

## Version History

Introduced: 6.0

# IDLitVisualization::Cleanup

The IDLitVisualization::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitVisualization::]Cleanup (*Only in subclass' Cleanup method.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::Get

The IDLitVisualization::Get function method retrieves object(s) from the visualization.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]Get([, /ALL] [, COUNT=*variable*] [, ISA=*string* or *array of strings*] [, POSITION=*index* or *array of indices*] [, /SKIP_PRIVATE])

## Return Value

Returns the reference of the object retrieved from the visualization. If the object is not contained by this visualization, a NULL object reference is returned.

## Arguments

None

## Keywords

### ALL

Set this keyword to return an array of object references to all of the objects in the container.

### COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function.

### ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

**Note**

This keyword is ignored if the ALL keyword is not provided.

### POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

### SKIP_PRIVATE

Set this keyword to indicate that this method should return only those objects that do not have the PRIVATE property set.

## Version History

Introduced: 6.0

# IDLitVisualization::GetCenterRotation

The IDLitVisualization::GetCenterRotation function method returns the center of rotation for this visualization.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]GetCenterRotation([, /DATA] [, /NO_TRANSFORM] [, XRANGE=[*xmin*, *xmax*]] [, YRANGE=[*ymin*, *ymax*]] [, ZRANGE=[*zmin*, *zmax*]])

## Return Value

Returns a two- or three-element vector, [*x*, *y*] or [*x*, *y*, *z*] indicating the center (in data coordinates) of the bounding box for this visualization if the center of rotation was not explicitly specified with the CENTER_OF_ROTATION property of this visualization. See the CENTER_OF_ROTATION property for more details.

## Arguments

None

## Keywords

### DATA

Set this keyword to indicate that the ranges should be computed for the full data sets of the contents of this visualization. By default (if the keyword is not set), the ranges are computed for the displayed portions of the data sets.

### NO_TRANSFORM

Set this keyword to indicate that this visualization's transform should not be applied when computing the *x*, *y*, and *z* ranges. By default, the transform is applied.

### XRANGE

Set this keyword to a named variable that will contain a 2-element vector, [*xmin*, *xmax*], representing the *x* range of the bounding box for this visualization.

### YRANGE

Set this keyword to a named variable that will contain a 2-element vector, [*ymin*, *ymax*], representing the *y* range of the bounding box for this visualization.

### ZRANGE

Set this keyword to a named variable that will contain a 2-element vector, [*zmin*, *zmax*], representing the *z* range of the bounding box for this visualization.

## Version History

Introduced: 6.0

# IDLitVisualization::GetCurrentSelectionVisual

The IDLitVisualization::GetCurrentSelectionVisual function method returns the currently active selection visual object for this visualization.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]GetCurrentSelectionVisual()

## Return Value

Returns a reference to an IDLitManipulatorVisual object. If no selection visual is currently active, the NULL object reference is returned.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::GetDataSpace

The IDLitVisualization::GetDataSpace function method returns a reference to the parent data space object within the graphics hierarchy that contains the visualization.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]GetDataSpace([, /UNNORMALIZED])

## Return Value

Returns a reference to the nearest data space object in the graphics hierarchy. If no data space objects are found by walking up the hierarchy, then a null object reference is returned.

## Arguments

None

## Keywords

### UNNORMALIZED

Set this keyword to indicate that the returned data space should be the parent data space that subclasses from the IDLitVisDataSpace class (which is not normalized) rather than the IDLitVisNormDataSpace class (which is normalized).

## Version History

Introduced: 6.0

# IDLitVisualization::GetDataString

The IDLitVisualization::GetDataString function method retrieves a description of this visualization's data at the given *x*, *y*, and *z* location.

**Note**

This method is designed to be implemented as needed by subclasses. The IDLitVisualization::GetDataString method simply always returns an empty string

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]GetDataString(*XYZLocation*)

## Return Value

Returns a string describing the visualization's data at the given location.

## Arguments

### XYZLocation

A three-element vector representing the *x*, *y*, and *z* location of the data for which a string description is to be returned.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::GetDefaultSelectionVisual

The IDLitVisualization::GetDefaultSelectionVisual function method returns an object that serves as the default selection visual for this visualization.

**Note**

If the visualization on which this method is called is not a manipulator target (see "MANIPULATOR_TARGET" on page 3039), the default selection visual returned by this method will be used as the current selection visual whenever the visualization is selected.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]GetDefaultSelectionVisual()

## Return Value

Returns a reference to an IDLitManipulatorVisual object.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::GetManipulatorTarget

The IDLitVisualization::GetManipulatorTarget function method retrieves the manipulator target associated with this visualization. The manipulator target may be this visualization itself.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]GetManipulatorTarget()

## Return Value

Returns an object reference to the manipulator target, or a NULL object reference if none is found.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::GetProperty

The IDLitVisualization::GetProperty procedure method retrieves the value of a property or group of properties for the object.

## Syntax

*Obj* -> [IDLitVisualization::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLitVisualization Properties” on page 3038 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitVisualization::GetSelectionVisual

The IDLitVisualization::GetSelectionVisual function method retrieves the selection visual for this visualization that corresponds to the given manipulator.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]GetSelectionVisual(*Manipulator*)

## Return Value

Returns a reference to an IDLitManipulatorVisual object that corresponds to the given manipulator. If this visualization already has a selection visual for the given manipulator, a reference to that selection visual is returned. Otherwise, a default selection visual will be requested from the manipulator, added to the visualization, and returned.

## Arguments

### Manipulator

Set this argument to a reference to an IDLitManipulator object that identifies the manipulator for which a selection visual is to be retrieved.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::GetTypes

The IDLitVisualization::GetTypes function method identifies the types that this visualization represents, including base types and any specializations.

**Note**

This method is designed to be implemented as needed by subclasses of the IDLitVisualization class. Calling this method on the IDLitVisualization class itself returns the following string array: [`'VISUALIZATION', '_VISUALIZATION',` *`AnySpecifiedTypes`*] where *`AnySpecifiedTypes`* are provided by any value set for the TYPE property of the IDLitVisualization class.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]GetTypes()

## Return Value

Returns a vector of strings identifying the types that this visualization represents. See "Predefined iTool Visualization Classes" in Chapter 6 of the *iTool Developer's Guide* manual for a list of predefined types

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::GetXYZRange

The IDLitVisualization::GetXYZRange function method computes the *x*, *y*, and *z* ranges of the overall contents of the visualization, taking into account the IMPACTS_RANGE property setting for itself and its contents.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]GetXYZRange(*XRange*,*YRange*, *ZRange* [, /DATA] [, /NO_TRANSFORM])

## Return Value

Returns a 1 if the *x*, *y*, and *z* ranges were successfully computed, or 0 otherwise.

## Arguments

### XRange

A named variable that, upon return, will contain a two-element vector, [*xmin*, *xmax*], representing the *x*-range of the contents of this visualization that impact ranges.

### YRange

A named variable that, upon return, will contain a two-element vector, [*ymin*, *ymax*], representing the *y*-range of the contents of this visualization that impact ranges.

### ZRange

A named variable that, upon return, will contain a two-element vector, [*zmin*, *zmax*], representing the *z*-range of the contents of this visualization that impact ranges.

## Keywords

### DATA

Set this keyword to indicate that the ranges should be computed for the full data sets of the contents of this visualization. By default, if the keyword is not set, the ranges are computed for the displayed portions of the data sets.

### NO_TRANSFORM

Set this keyword to indicate that this visualization's transform matrix should not be applied when computing the *x*, *y*, and *z* ranges. By default, the transform matrix is applied.

## Version History

Introduced: 6.0

# IDLitVisualization::Init

The IDLitVisualization::Init function method initializes the visualization object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitVisualization' [, *PROPERTY*=*value*] )

or

*Result* = *Obj* -> [IDLitVisualization::]Init([*PROPERTY*=*value*])
(*Only in a subclass' Init method.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLitVisualization Properties" on page 3038 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitVisualization::Is3D

The IDLitVisualization::Is3D function method determines whether or not this visualization (or any of its contents) is marked as being three-dimensional.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]Is3D()

## Return Value

Returns 1 if this visualization is marked as being three-dimensional, or 0 if it is not three-dimensional.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::IsIsotropic

The IDLitVisualization::IsIsotropic function method indicates whether or not this visualization (or any of its contents) is marked as being isotropic. See the ISOTROPIC property for more information.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]IsIsotropic()

## Return Value

Returns 1 if the visualization or any of the items it contains has the ISOTROPIC property set, or 0 otherwise.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::IsManipulatorTarget

The IDLitVisualization::IsManipulatorTarget function method determines whether or not this visualization is a manipulator target.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]IsManipulatorTarget()

## Return Value

Returns 1 if this visualization is a manipulator target, or 0 if it is not.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::IsSelected

The IDLitVisualization::IsSelected function method determines if this visualization is currently selected or not.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]IsSelected()

## Return Value

Returns 1 if this visualization is currently selected, or 0 if it is not selected.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::OnDataChange

The IDLitVisualization::OnDataChange procedure method ensures that objects that use the visualization's data are notified when the visualization's data changes.

**Note**

This method is generally not called explicitly.

## Syntax

*Obj* -> [IDLitVisualization::]OnDataChange, *Notifier*

## Arguments

### Notifier

A reference to the object that is sending notification when the data changes.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::OnDataComplete

The IDLitVisualization::OnDataComplete procedure method ensures that objects that use the visualization's data are notified when changes to the visualization's data are complete.

**Note**

This method is generally not called explicitly.

## Syntax

*Obj* -> [IDLitVisualization::]OnDataComplete, *Notifier*

## Arguments

### Notifier

A reference to the object that is sending notification when the data changes are complete.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::OnDataRangeChange

The IDLitVisualization::OnDataRangeChange procedure method ensures that objects that use the visualization's data are notified when the range of the visualization's data changes.

**Note**

This method is generally not called explicitly.

## Syntax

*Obj* -> [IDLitVisualization::]OnDataRangeChange, *Notifier*, *XRange*, *YRange*, *Zrange*

## Arguments

### Notifier

A reference to the object that is sending notification when the data range changes.

### XRange

A two-element vector, [*xmin*, *xmax*], representing the new *x*-range.

### YRange

A two-element vector, [*ymin*, *ymax*], representing the new *y*-range.

### ZRange

A two-element vector, [*zmin*, *zmax*], representing the new *z*-range.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::Remove

The IDLitVisualization::Remove procedure method removes the given object(s) from the visualization.

## Syntax

*Obj* -> [IDLitVisualization::]Remove, *Object*

## Arguments

### Object

A reference (or vector of references) to the object(s) to be removed from this visualization.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::Scale

The IDLitVisualization::Scale procedure method scales the visualization by the given scale factors.

## Syntax

*Obj* -> [IDLitVisualization::]Scale, *SX*, *SY*, *SZ* [, CENTER_OF_ROTATION=[*x*, *y*] | [*x*, *y*, *z*]] [, /PREMULTIPLY]

## Arguments

### SX

The factor in the *x*-dimension by which the visualization is to be scaled.

### SY

The factor in the *y*-dimension by which the visualization is to be scaled.

### SZ

The factor in the *z*-dimension by which the visualization is to be scaled.

## Keywords

**Note**

This method accepts all keywords accepted by the Scale method of the visualization's current selection visual. In addition, the following keywords are accepted:

### CENTER_OF_ROTATION

Set this keyword to a 3-element vector, [*x*,*y*,*z*], representing the center of rotation (in data coordinates) to be used as the center for scaling. By default, if PREMULTIPLY is set, then this visualization’s own center of rotation will be used as the center for scaling; if PREMULTIPLY is not set, the result of transforming this visualization’s center of rotation by its own transformation matrix will be used as the center for scaling.

### PREMULTIPLY

Set this keyword to cause the scaling matrix specified by *Sx*, *Sy*, and *Sz* to be pre-multiplied to this visualization's transformation matrix. By default, the scaling matrix is post-multiplied.

## Version History

Introduced: 6.0

# IDLitVisualization::Select

The IDLitVisualization::Select procedure method handles notification of mechanisms that key off the current selection (such as the visualization browser) when this visualization has been selected.

## Syntax

*Obj* -> [IDLitVisualization::]Select[, *Mode*]
[, /ADDITIVE | /SELECT | /TOGGLE | /UNSELECT] [, /NO_NOTIFY]

## Arguments

### Mode

A scalar that indicates the selection mode. Valid values include:

- 0 - Unselect (deselect this visualization).
- 1 - Select (set this visualization as the current selection). This mode is the default.
- 2 - Toggle (toggle the selection of this visualization). Use the **CRTL** key to toggle.
- 3 - Additive (add this visualization to the current selection list). Use the **SHIFT** key to add.

## Keywords

### ADDITIVE

Set this keyword to indicate that the selection mode is additive. This is equivalent to setting *Mode* to 3.

### NO_NOTIFY

Set this keyword to indicate that this visualization's parent should not be notified of this selection. By default, the parent is notified.

### SELECT

Set this keyword to indicate that the selection mode is select. This is equivalent to setting *Mode* to 1.

### TOGGLE

Set this keyword to indicate that the selection mode is toggle. This is equivalent to setting *Mode* to 2.

### UNSELECT

Set this keyword to indicate that the selection mode is unselect. This is equivalent to setting *Mode* to 0.

## Version History

Introduced: 6.0

# IDLitVisualization::Set3D

The IDLitVisualization::Set3D procedure method sets a flag indicating this visualization is three-dimensional.

## Syntax

*Obj* -> [IDLitVisualization::]Set3D, *Is3D* [, /ALWAYS] [, /AUTO_COMPUTE]

## Arguments

### Is3D

A non-zero value indicates that the visualization is three-dimensional; 0 indicates that it is two-dimensional.

## Keywords

### ALWAYS

Set this keyword to indicate that the given 3D setting always applies.

### AUTO_COMPUTE

Set this keyword to indicate that the 3D setting for this visualization should be auto-computed based upon the dimensionality of its contents. This keyword is mutually exclusive of the ALWAYS keyword, and the *Is3D* argument is ignored if AUTO_COMPUTE is set.

## Version History

Introduced: 6.0

# IDLitVisualization::SetCurrentSelectionVisual

The IDLitVisualization::SetCurrentSelectionVisual procedure method sets the current selection visual for the given manipulator.

## Syntax

*Obj* -> [IDLitVisualization::]SetCurrentSelectionVisual, *Manipulator*

## Arguments

### Manipulator

An object reference (that subclasses from IDLitManipulator) identifying the manipulator that corresponds to the selection visual to be set as current.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::SetData

The IDLitVisualization::SetData function method sets the data parameter of the visualization.

**Note**

If the SetData method returns successfully, notification of a data change is issued to all observers of the data object.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]SetData(*Data*)

## Return Value

Returns a 1 if successful, or 0 if it fails.

## Arguments

### Data

A reference to the data object to be associated with the visualization parameter.

## Keywords

This method accepts all keywords accepted by the IDLitParameter::SetData method.

## Version History

Introduced: 6.0

# IDLitVisualization::SetDefaultSelectionVisual

The IDLitVisualization::SetDefaultSelectionVisual procedure method sets the default selection visual to be associated with this visualization.

**Note**

If the visualization on which this method is called is not a manipulator target (see "MANIPULATOR_TARGET" on page 3039) the default selection visual set by this method will be used as the current selection visual whenever the visualization is selected.

## Syntax

*Obj* -> [IDLitVisualization::]SetDefaultSelectionVisual, *SelectionVisual* [, POSITION=*value*]

## Arguments

### SelectionVisual

A reference to the IDLitManipulatorVisual object that is added to the visualization object and serves as the default selection visual for this visualization.

## Keywords

### POSITION

Set this keyword equal to the zero-based position at which the selection visual should be inserted within the container. The default is to add the object to the end of the container (the visualization object).

## Version History

Introduced: 6.0

# IDLitVisualization::SetParameterSet

The IDLitVisualization::SetParameterSet function method associates a parameter set with this visualization.

**Note**

If the SetParameterSet method returns successfully, notification of a data change is issued to all observers of the visualization's data.

## Syntax

*Result* = *Obj* -> [IDLitVisualization::]SetParameterSet(*ParameterSet*)

## Return Value

Returns a 1 if successful, or a 0 otherwise.

## Arguments

### ParameterSet

A reference to the IDLitParameterSet object to be associated with the visualization.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::SetProperty

The IDLitVisualization::SetProperty procedure method sets the value of a property or group of properties for the object.

## Syntax

*Obj* -> [IDLitVisualization::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLitVisualization Properties” on page 3038 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitVisualization::UpdateSelectionVisual

The IDLitVisualization::UpdateSelectionVisual procedure method transforms this visualization's selection visual to match the visualization's geometry.

## Syntax

*Obj* -> [IDLitVisualization::]UpdateSelectionVisual

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitVisualization::VisToWindow

The IDLitVisualization::VisToWindow procedure method transforms given points from visualization data space to window device coordinates.

## Syntax

*Obj* -> [IDLitVisualization::]VisToWindow, *InX*, *InY, InZ, OutX*, *OutY, OutZ* [, /NO_TRANSFORM]

or

*Obj* -> [IDLitVisualization::]VisToWindow, *InX*, *InY, OutX*, *OutY* [, /NO_TRANSFORM]

or

*Obj* -> [IDLitVisualization::]VisToWindow, *InVerts*, *OutVerts* [, /NO_TRANSFORM]

## Arguments

### InX

A vector of input X values (in visualization data space).

### InY

A vector of input Y values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

### InZ

A vector of input Z values (in visualization data space). The number of elements of this vector must match the number of elements in *InX*.

### InVerts

A [2, *n*] or [3, *n*] array of input vertices (in visualization data space).

### OutX

A named variable that will contain a vector of output X values (in window device coordinates).

### OutY

A named variable that will contain a vector of output Y values (in window device coordinates).

### OutZ

A named variable that will contain a vector of output Z values (in window device coordinates).

### OutVerts

A named variable that will contain a vector of output vertices (in window device coordinates).

## Keywords

### NO_TRANSFORM

If this keyword is set, the current transformation matrix is not included in the computation. Setting this keyword is useful when computing selection visual scaling.

## Version History

Introduced: 6.0

# IDLitVisualization::WindowToVis

The IDLitVisualization::WindowToVis procedure method transforms given points from window device coordinates to visualization data space.

## Syntax

*Obj* -> [IDLitVisualization::]WindowToVis, *InX*, *InY*, *InZ*, *OutX*, *OutY*, *OutZ*

or

*Obj* -> [IDLitVisualization::]WindowToVis, *InX*, *InY*, *OutX*, *OutY*

or

*Obj* -> [IDLitVisualization::]WindowToVis, *InVerts*, *OutVerts*

## Arguments

### InX

A vector representing the input x values (in window device coordinates).

### InY

A vector representing the input y values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

### InZ

A vector representing the input z values (in window device coordinates). The number of elements of this vector must match the number of elements in *InX*.

### InVerts

A [2, *n*] or [3, *n*] array representing the input vertices (in window device coordinates).

### OutX

A named variable that upon return will contain a vector representing the output x values (in visualization data space).

### OutY

A named variable that upon return will contain a vector representing the output y values (in visualization data space).

### OutZ

A named variable that upon return will contain a vector representing the output z values (in visualization data space).

### OutVerts

A named variable that upon return will contain a vector representing the output vertices (in visualization data space).

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow

The IDLitWindow class serves as the base class for all windows within the iTools framework.

## Superclasses

IDLgrWindow

## Creation

See "IDLitWindow::Init" on page 3105.

## Properties

Objects of this class have the following properties. See "IDLitWindow Properties" on page 3086 for details on individual properties.

- COLOR_MODEL
- CURRENT_ZOOM
- DESCRIPTION
- DIMENSIONS
- DISPLAY_NAME (X Only)
- GRAPHICS_TREE
- LOCATION
- MINIMUM_VIRTUAL_DIMENSIONS
- NAME
- N_COLORS
- PALETTE
- QUALITY
- RENDERER
- RETAIN
- TITLE
- UNITS

- UVALUE
- VIRTUAL_DIMENSIONS
- VISIBLE_LOCATION
- ZOOM_BASE
- ZOOM_NSTEP

In addition, objects of this class inherit the properties of its superclass.

## Methods

This class has the following methods:

- IDLitWindow::Add
- IDLitWindow::AddWindowEventObserver
- IDLitWindow::Cleanup
- IDLitWindow::ClearSelections
- IDLitWindow::DoHitTest
- IDLitWindow::GetEventMask
- IDLitWindow::GetProperty
- IDLitWindow::GetSelectedItems
- IDLitWindow::Init
- IDLitWindow::OnKeyboard
- IDLitWindow::OnMouseDown
- IDLitWindow::OnMouseMotion
- IDLitWindow::OnMouseUp
- IDLitWindow::OnScroll
- IDLitWindow::Remove
- IDLitWindow::RemoveWindowEventObserver
- IDLitWindow::SetCurrentZoom
- IDLitWindow::SetEventMask
- IDLitWindow::SetManipulatorManager
- IDLitWindow::SetProperty

- IDLitWindow::ZoomIn
- IDLitWindow::ZoomOut

In addition, this class inherits the methods of its superclass.

## Version History

Introduced: 6.0

# IDLitWindow Properties

IDLitWindow objects have the following properties. Properties with the word “Yes” in the “Get” column of the table can be retrieved via IDLitWindow::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be set via IDLitWindow::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLitWindow::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## COLOR_MODEL

An integer value representing the color model to be used for the window:

- 0 = RGB (default)
- 1 = Color Index

**Note**

For some X11 display situations, IDL may not be able to support a color index model destination object in Object Graphics. We do, however, guarantee that an RGB color model destination will be available for all display situations.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Color model | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## CURRENT_ZOOM

A named variable that upon return will contain a floating point value representing the current zoom factor associated with this window.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Zoom Factor | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** Yes |

## DESCRIPTION

A string representing the full name or description of this object.

| **Property Type** | STRING | | |
|---|---|---|---|
| **Name String** | Description | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DIMENSIONS

A two-element vector of the form [*width, height*] to specify the dimensions of the window in units specified by the UNITS property. By default, if no value is specified for DIMENSIONS, IDL uses the value of the “Default Window Width” and “Default Window Height” preferences set in the IDL Development Environment’s (IDLDE) Preferences dialog. If there is no preference file for the IDLDE, the DIMENSIONS property is set equal to one quarter of the screen size. There are limits on the maximum size of an IDLgrWindow object.

**Note**

Changing DIMENSIONS properties is merely a request and may be ignored for various reasons.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Zoom Factor | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DISPLAY_NAME (X Only)

A string containing the name of the X Windows display on which the window is to appear.

| **Property Type** | STRING | | |
|---|---|---|---|
| **Name String** | Display Name | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView describing the graphics tree of this window object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

| | | | |
|---|---|---|---|
| **Property Type** | Object Reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LOCATION

A two-element vector of the form [*x*, *y*] to specify the location of the upper left corner of the window relative to the display screen, in units specified by the UNITS property. By default, the window is positioned at one of four quadrants on the display screen, and the location is measured in device units.

**Note**

Changing LOCATION properties is merely a request and may be ignored for various reasons. LOCATION may be adjusted to take into account window decorations.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Location | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## MINIMUM_VIRTUAL_DIMENSIONS

A two-element vector, [*width*, *height*], specifying the minimum dimensions allowed for the virtual canvas of this window. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default value of this property is [0, 0], a value indicating that the minimum virtual dimensions should match the current virtual dimensions.

| | |
|---|---|
| **Property Type** | Vector |

| **Name String** | *not displayed* | | |
|---|---|---|---|
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## NAME

A string representing the human-readable name of this object.

| **Property Type** | STRING | | |
|---|---|---|---|
| **Name String** | Name | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## N_COLORS

An integer value representing the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Indexed (1). This property is ignored if COLOR_MODEL is set to RGB (0).

**Note**

If COLOR_MODEL is set to color index (1), setting N_COLORS is treated as a request to your operating system. You should always check the actual number of available colors for any Color Indexed destination with the IDLgrWindow::GetProperty method. The actual number of available colors depends on your system and also on how you have used IDL.

| **Property Type** | INTEGER | | |
|---|---|---|---|
| **Name String** | Number of colors | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## PALETTE

The object reference of a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the graphics destination’s color lookup table, applicable if the Indexed color model is used.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## QUALITY

An integer value indicating the rendering quality at which graphics are to be drawn to this destination. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default).

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Draw quality | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## RENDERER

An integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See "Hardware vs. Software Rendering" in Using IDL for details. Your choice of renderer may also affect the maximum size of an IDLitWindow object.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Draw quality | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## RETAIN

An integer value to specify how backing store should be handled for the window. By default, if no value is specified for RETAIN, IDL uses the value of the "Backing Store" preference set in the IDL Development Environment's (IDLDE) Preferences dialog. If there is no preference file for the IDLDE (that is, if you always use IDL in plain tty mode), the RETAIN property is set equal to 0 by default.

- 0 = No backing store

- 1 = The server or window system is requested to provide the backing store. Note that requesting backing store from the server is only a request; backing store may not be provided in all situations
- 2 = Requests that IDL provide the backing store directly. In some situations, IDL can not provide this backing store in Object Graphics. To see if IDL provided backing store, query the RETAIN property of IDLitWindow::GetProperty. IDL may also alter the RENDERER property while attempting to provide backing store

**Note**

If you are using software rendering (that is, the RENDERER property is set equal to one), IDL will refresh the window automatically regardless of the setting of the RETAIN property.

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Retain | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## TITLE

A string representing the title of the window.

| | | | |
|---|---|---|---|
| **Property Type** | STRING | | |
| **Name String** | Title | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## UNITS

An integer value indicating the units of measure for the LOCATION and DIMENSIONS properties. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the screen

**Note**

If you set the value of the UNITS property (using the SetProperty method) without also setting the value of the LOCATION and DIMENSIONS properties, IDL will convert the current size and location values into the new units.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Units | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## UVALUE

A value of any type containing any information you wish. If you set this user value equal to a pointer or object reference that does not belong to a container, you should explicitly destroy that pointer or object reference when destroying the object of which this property is a user value.

| **Property Type** | User Defined | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## VIRTUAL_DIMENSIONS

A two-element vector, [*width*, *height*], specifying the dimensions of the *virtual canvas* for this window. In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time. The default value of this property is [0, 0], a value indicating that the virtual canvas dimensions should match the visible dimensions (as specified via the DIMENSIONS property).

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Virtual dimensions | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## VISIBLE_LOCATION

A two-element vector, [*x*, *y*], specifying the lower left coordinate of the visible portion of the canvas (relative to the virtual canvas). In a scrolling window, the virtual canvas represents the full canvas, of which only a smaller visible portion is displayed at any given time.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Visible Location | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ZOOM_BASE

A floating point value representing the base value by which the window's current zoom factor will be multiplied or divided for zooming in or zooming out. The default is 2.0.

| **Property Type** | Float | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZOOM_NSTEP

A named variable that, upon return, will contain an integer that indicates the number of times this window's ZOOM_BASE property has been applied to achieve the current zoom factor. A positive value indicates that the current zoom factor represents the result of zooming in ZOOM_NSTEP times. A negative value indicates that the current zoom factor represents the result of zooming out -ZOOM_NSTEP times.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLitWindow::Add

The IDLitWindow::Add procedure method adds the given object(s) to the window.

## Syntax

*Obj* -> [IDLitWindow::]Add, *Objects* [, POSITION=*value*]

## Arguments

### Objects

A reference (or array of references) to the object(s) to be added to the window. Any of the objects that inherit from IDLgrViewGroup are added directly to the window's scene, which represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window. The remaining objects are added to the current view within the window's scene.

## Keywords

### POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the position within the container at which the new object should be placed.

## Version History

Introduced: 6.0

# IDLitWindow::AddWindowEventObserver

The IDLitWindow::AddWindowEventObserver procedure method adds the given object(s) to the list of observers that are to be notified of events that occur within this window. Each observer must support the following methods:

- OnKeyboard
- OnMouseDown
- OnMouseMotion
- OnMouseUp

When an event occurs within this window, the corresponding method (from the list above) will be called for each observer in the window's list.

## Syntax

*Obj* -> [IDLitWindow::]AddWindowEventObserver, *Objects*

## Arguments

### Objects

A reference (or vector of references) to the object(s) to be added as window event observers.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::Cleanup

The IDLitWindow::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitWindow::]Cleanup (only in subclass' *Cleanup* method)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::ClearSelections

The IDLitWindow::ClearSelections procedure method clears the window's list of currently selected items (within its current view). The items within the current view that had been selected are deselected.

## Syntax

*Obj* -> [IDLitWindow::]ClearSelections

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::DoHitTest

The IDLitWindow::DoHitTest function method performs a hit test to determine which visualizations within the destination are displayed at a given pixel location.

**Note**

The objects returned in *Result* are the “top-level” objects (usually IDLgrModel or IDLitVisualization objects). Objects *contained* by he returned objects can be returned using the SUB_HIT keyword.

## Syntax

*Result* = *Obj* -> DoHitTest(*X*, *Y* [, DIMENSIONS=[*width*, *height*]] [, SUB_HIT=*variable*] [, UNITS={0 | 1 | 2 | 3}])

## Return Value

Returns a vector of references to the IDLitVisualizations that appear at the given location. If no visualizations are displayed at that location, a null reference is returned.

## Arguments

### X

A floating-point value representing the *x*-location at which the hit test is to be performed

### Y

A floating-point value representing the *y*-location at which the hit test is to be performed.

## Keywords

### DIMENSIONS

Set this keyword to a two-element integer vector, [*w*, *h*], to specify the dimensions (width and height) of the hit test box. The hit test box is centered at the location specified by the *X* and *Y* arguments. Any object that falls within this hit test box will be included in the return vector. By default, the hit test box is 3 pixels by 3 pixels.

### SUB_HIT

Set this keyword to a named variable that will contain references to all *contained* visualization objects that satisfy all of the following conditions:

- the objects are contained by the nearest hit visualization (the first object in the return value),
- the objects are SELECT_TARGETs (see "IDLgrModel" on page 3343), and
- the objects are actively displayed at the given *X* and *Y* coordinates.

### UNITS

Set this keyword to a scalar value to indicate the units of measure for the *X*, *Y* arguments and the DIMENSIONS keyword. Valid values include:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of this window

## Version History

Introduced: 6.0

# IDLitWindow::GetEventMask

The IDLitWindow::GetEventMask function method returns a bitwise mask representing the events that are enabled for this window.

## Syntax

*Result* = *Obj* -> [IDLitWindow::]GetEventMask([, BUTTON_EVENTS=*variable*] [, KEYBOARD_EVENTS=*variable*] [, /MOTION_EVENTS=*variable*] [, /TRACKING_EVENTS=*variable*])

## Return Value

Returns the bitwise mask as an unsigned long integer. The bits in the mask are as follows:

| Bit | Value | Event |
|---|---|---|
| 0 | 1 | Button Events |
| 1 | 2 | Motion Events |
| 2 | 4 | Keyboard Events |
| 3 | 8 | Tracking Events |

*Table 115: Bits of the Event Mask*

## Arguments

None

## Keywords

### BUTTON_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if mouse button events are currently enabled for this window, or a 0 otherwise.

### KEYBOARD_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if keyboard events are currently enabled for this window, or a 0 otherwise.

### MOTION_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if mouse motion events are currently enabled for this window, or a 0 otherwise.

### TRACKING_EVENTS

Set this keyword to a named variable that upon return will contain a 1 if tracking events are currently enabled for this window, or a 0 otherwise.

## Version History

Introduced: 6.0

# IDLitWindow::GetProperty

The IDLitWindow::GetProperty procedure method retrieves the value of an IDLitWindow property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclass.

## Syntax

*Obj* -> [IDLitData::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLitWindow Properties” on page 3086 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitWindow::GetSelectedItems

The IDLitWindow::GetSelectedItems function method returns the currently selected objects within this window's scene, which represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window.

## Syntax

*Result* = *Obj*->[IDLitWindow::]GetSelectedItems([, /COUNT])

## Return Value

Returns a vector of references to the objects currently selected within this window's scene. If no objects are currently selected, this function returns a –1.

## Arguments

None

## Keywords

### COUNT

Set this keyword to a named variable that will contain the number of items returned by this method.

## Version History

Introduced: 6.0

# IDLitWindow::Init

The IDLitWindow::Init function method initializes the window object.

This function method initializes the IDLitWindow object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitWindow'[, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLitWindow::]Init([, *PROPERTY=value*])
(*Only in subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

## Arguments

None

## Keywords

Any property listed under “IDLitWindow Properties” on page 3086 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitWindow::OnKeyboard

The IDLitWindow::OnKeyboard procedure method handles notification (from the native window device) that a keyboard event has occurred, and passes along that notification to all observers in the list of window event observers.

# Syntax

*Obj* -> [IDLitWindow::]OnKeyboard, *IsAlphaNumeric*, *Character*, *KeySymbol*

# Arguments

## IsAlphaNumeric

A byte that is non-zero if the keyboard event corresponds to an alphanumeric character, in which case the ASCII character will be placed in the *Character* argument. If the keyboard event does not correspond to an alphanumeric character, then *IsAlphaNumeric* will be zero, and the symbol for the key that was pressed will be placed in the *KeySymbol* argument.

## Character

A string that is set to the ASCII character that corresponds to the key that was pressed if *IsAlphaNumeric* is non-zero. Otherwise, this argument is set to zero.

## KeySymbol

A string that is set to an unsigned long integer that indicates the key that was pressed if *IsAlphaNumeric* is zero. Otherwise, this argument is set to zero. Valid values for key symbols include:

- 1 = Backspace
- 2 = Tab
- 3 = Return

# Keywords

None

# Version History

Introduced: 6.0

# IDLitWindow::OnMouseDown

The IDLitWindow::OnMouseDown procedure method handles notification (from the native window device) that a mouse down event has occurred, and passes along that notification to all observers in the list of window event observers.

## Syntax

*Obj* -> [IDLitWindow::]OnMouseDown, *X, Y, ButtonMask, Modifiers, NumClicks*

## Arguments

### X

A floating-point value representing the *x*-location (in device coordinates) of the mouse event.

### Y

A floating-point value representing the *y*-location (in device coordinates) of the mouse event.

### ButtonMask

An integer value of a bitwise mask indicating which of the left, center, or right mouse button was pressed:

| Bitmask | Mouse Button |
|---|---|
| 1 | Left |
| 2 | Middle |
| 4 | Right |

*Table 116: Bitmask for Button Events*

### Modifiers

An integer value of a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

| Bit | Value | Modifier Key |
|---|---|---|
| 0 | 1 | Shift |
| 1 | 2 | Control |
| 2 | 4 | Caps Lock |
| 3 | 8 | Alt |

*Table 117: Bits of the Modifier Key Mask*

### NumClicks

An integer value indicating the number of times the mouse button was clicked.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::OnMouseMotion

The IDLitWindow::OnMouseMotion procedure method handles notification (from the native window device) that a mouse motion event has occurred, and passes along that notification to all observers in the list of window event observers.

## Syntax

*Obj* -> [IDLitWindow::]OnMouseMotion, *X*, *Y*, *Modifiers*

## Arguments

### X

A floating-point value representing the *x*-location (in device coordinates) of the mouse event.

### Y

A floating-point value representing the *y*-location (in device coordinates) of the mouse event.

### Modifiers

An integer value of a bitwise mask indicating which modifier keys are active at the time the mouse button is pressed. If a bit is zero, the key is up; if the bit is set, the key is pressed. The following table describes the bits in this bitmask:

| Bit | Value | Modifier Key |
|---|---|---|
| 0 | 1 | Shift |
| 1 | 2 | Control |
| 2 | 4 | Caps Lock |
| 3 | 8 | Alt |

*Table 118: Bits of the Modifier Key Mask*

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::OnMouseUp

The IDLitWindow::OnMouseUp procedure method handles notification (from the native window device) that a mouse up event has occurred, and passes along that notification to all observers in the list of window event observers.

# Syntax

*Obj* -> [IDLitWindow::]OnMouseUp, *X*, *Y*, *ButtonMask*

# Arguments

## X

A floating-point value representing the *x*-location (in device coordinates) of the mouse event.

## Y

A floating-point value representing the *y*-location (in device coordinates) of the mouse event.

## ButtonMask

An integer value of a bitwise mask indicating which of the left, center, or right mouse button was pressed:

| Bitmask | Mouse Button |
|---|---|
| 1 | Left |
| 2 | Middle |
| 4 | Right |

*Table 119: Bitmask for Button Events*

# Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::OnScroll

The IDLitWindow::OnScroll procedure method handles notification (from the native window device) that a scrolling event has occurred. This notification is passed on to the window's scene, which handles the cropping of each of its contained views. A scene represents a container for all of the views (and their corresponding visualization hierarchies) that appear within a window.

## Syntax

*Obj* -> [IDLitWindow::]OnScroll, *X*, *Y*

## Arguments

### X

A floating-point value representing the *x*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

### Y

A floating-point value representing the *y*-coordinate of the lower left corner of the visible portion of the canvas (in device coordinates) after the scroll.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::Remove

The IDLitWindow::Remove procedure method removes the given object(s) from the window.

## Syntax

*Obj* -> [IDLitWindow::]Remove, *Object* [, /ALL] [, POSITION=index]

## Arguments

### Object

A reference (or vector of references) to the object(s) to be removed from this window.

## Keywords

### ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Object* argument is not required.

### POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Object* argument is supplied, this keyword is ignored.

## Version History

Introduced: 6.0

# IDLitWindow::RemoveWindowEventObserver

The IDLitWindow::RemoveWindowEventObserver procedure method removes the given object(s) from the list of observers that are notified of events that occur within this window.

## Syntax

*Obj* -> [IDLitWindow::]RemoveWindowEventObserver, *Objects*

## Arguments

### Objects

A reference (or vector of references) to the object(s) to be removed from the list of window event observers.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::SetCurrentZoom

The IDLitWindow::SetCurrentZoom procedure method sets the current zoom factor for this window by changing its virtual dimensions. The contents of the window are updated to reflect the new zoom factor.

## Syntax

*Obj* -> [IDLitWindow::]SetCurrentZoom, *ZoomFactor* [, /RESET]

## Arguments

### ZoomFactor

A positive floating point value indicating the zoom factor to be applied to the window. Values less than 1.0 result in a zooming out; values greater than 1.0 result in a zooming in on the contents of the window.

## Keywords

### RESET

Set this keyword to indicate that the zoom factor should be reset to 1.0. If this keyword is present, the *ZoomFactor* argument is ignored.

## Version History

Introduced: 6.0

# IDLitWindow::SetEventMask

The IDLitWindow::SetEventMask procedure method enables the given events within this window.

When an event occurs within this window, if the corresponding event type is enabled, then the list of its window event observers will be notified of the event. See “IDLitWindow::AddWindowEventObserver” on page 3096 for more details.

## Syntax

*Obj* -> [IDLitWindow::]SetEventMask([*EventMask*] [, /BUTTON_EVENTS] [, /KEYBOARD_EVENTS] [, /MOTION_EVENTS] [, /TRACKING_EVENTS])

## Arguments

### EventMask

An unsigned long integer representing the bitwise mask for the events that are to be enabled for this window. The bits in the mask are as follows:

| Bit | Value | Event |
|---|---|---|
| 0 | 1 | Button Events |
| 1 | 2 | Motion Events |
| 2 | 4 | Keyboard Events |
| 3 | 8 | Tracking Events |

*Table 120: Bits of the Event Mask*

This argument is optional; the keywords described below may be used instead.

## Keywords

### BUTTON_EVENTS

Set this keyword to indicate that mouse button events are to be enabled for this window.

### KEYBOARD_EVENTS

Set this keyword to indicate the keyboard events are to be enabled for this window.

### MOTION_EVENTS

Set this keyword to indicate that mouse motion events are to be enabled for this window.

### TRACKING_EVENTS

Set this keyword to indicate that tracking events are to be enabled for this window.

## Version History

Introduced: 6.0

# IDLitWindow::SetManipulatorManager

The IDLitWindow::SetManipulatorManager procedure method sets the given IDLitManipulatorManager object as the current manager of this window's manipulators.

## Syntax

*Obj* -> [IDLitWindow::]SetManipulatorManager, *Manager*

## Arguments

### Manager

A reference to the IDLitManipulatorManager object that is to serve as the manager for this window's manipulators.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::SetProperty

The IDLitWindow::SetProperty procedure method sets the value of an IDLitWindow property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

## Syntax

*Obj* -> [IDLitWindow::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLitWindow Properties” on page 3086 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitWindow::ZoomIn

The IDLitWindow::ZoomIn procedure method causes the current zoom factor for this window to be increased (that is, multiplied by the factor given by the window's ZOOM_BASE property). The contents of the window are updated to reflect the new zoom factor. See "IDLitWindow::SetCurrentZoom" on page 3117 for additional details.

## Syntax

*Obj* -> [IDLitWindow::]ZoomIn

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWindow::ZoomOut

The IDLitWindow::ZoomOut procedure method causes the current zoom factor for this window to be decreased (that is, divided by the factor given by the window's ZOOM_BASE property). The contents of the window are updated to reflect the new zoom factor. See "IDLitWindow::SetCurrentZoom" on page 3117 for additional details.

## Syntax

*Obj* -> [IDLitWindow::]ZoomOut

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWriter

The IDLitWriter class defines the interface used to construct file writers for the iTools framework. Objects of this class are not intended to be created as standalone entities; rather, this class should be included as the superclass of an iTool file writer class.

This class is written in the IDL language. Its source code can be found in the file `idlitwriter__define.pro` in the `lib/itools/framework` subdirectory of the IDL distribution.

## Superclasses

IDLitComponent

IDLitIMessaging

## Creation

See "IDLitWriter::Init" on page 3131.

## Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

## Methods

This class has the following methods:

- IDLitWriter::Cleanup
- IDLitWriter::GetFileExtensions
- IDLitWriter::GetFilename
- IDLitWriter::GetProperty
- IDLitWriter::Init
- IDLitWriter::IsA
- IDLitWriter::SetData

- IDLitWriter::SetFilename
- IDLitWriter::SetProperty

In addition, this class inherits the methods of its superclasses.

## Examples

See Chapter 9, “Creating a File Writer” in the *iTool Developer’s Guide* manual for examples using this class and its methods.

## Version History

Introduced: 6.0

# IDLitWriter Properties

Objects of this class do not have any properties of their own, but do have properties inherited from any superclasses.

# IDLitWriter::Cleanup

The IDLitWriter::Cleanup procedure method performs all cleanup on the object, and should be called by the subclass' Cleanup method.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLitWriter::]Cleanup (*Only in subclass' Cleanup method.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWriter::GetFileExtensions

The IDLitWriter::GetFileExtensions method is called by the system to retrieve the file extensions supported by this particular writer.

## Syntax

*Result* = *Obj* -> [IDLitWriter::]GetFileExtensions([COUNT=*count*])

## Return Value

Returns a scalar or string array that contains the file extensions associated with this writer.

## Arguments

None

## Keywords

### COUNT

Set this keyword to a named variable that will contain the number of file extensions returned by this method.

## Version History

Introduced: 6.0

# IDLitWriter::GetFilename

The IDLitWriter::GetFilename function method is called by the system to retrieve the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time. This method allows direct access to the file currently associated with the writer.

In addition, this methodology is helpful when multiple writes are performed from a given file.

## Syntax

*Result* = *Obj* -> [IDLitWriter::]GetFilename()

## Return Value

Returns a string containing the current file name associated with this writer, or an empty string if no filename has been associated.

## Arguments

None

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWriter::GetProperty

The IDLitWriter::GetProperty procedure method retrieves the value of an IDLitWriter property, and should be called by the subclass' GetProperty method. This method also retrieves properties defined in the superclasses.

## Syntax

*Obj* -> [IDLitWriter::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under "IDLitReader Properties" on page 2956 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 6.0

# IDLitWriter::Init

The IDLitWriter::Init function method initializes the IDLitWriter object, and should be called by the subclass' Init method. This method also calls the superclass' Init method.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: if you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLitWriter', *Extensions* [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLitWriter::]Init(*Extensions* [, *PROPERTY=value*])
(*Only in subclass' Init method.*)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or 0 otherwise.

## Arguments

### Extensions

A scalar or string array that contains the file extensions that are common for this file type. These values should not include the period that is often associated with file extensions (a correct value is "jpeg" not ".jpeg").

## Keywords

Any property listed under “IDLitReader Properties” on page 2956 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0

# IDLitWriter::IsA

The IDLitWriter::IsA function method is called by the system to determine if the given file is of the type supported by this file writer. Often this is used to determine what file writer to use when opening a new file.

The default behavior provided by this method is to check the file extension on the provided file name with the extensions provided to this object during initialization.

When a new writer is implemented, the default behavior can be used, or the developer can provide further logic to determine if the provided file is the correct type.

## Syntax

*Result* = *Obj* -> [IDLitWriter::]IsA(*Filename*)

## Return Value

Returns a 1 if the writer supports this type of file, or a 0 if the writer does not support this type of file.

## Arguments

### Filename

A string scalar representing of the filename, which is used to check and determine if the writer supports its format.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWriter::SetData

The IDLitWriter::SetData function method is called by the system to set the data for the current file. When called, the writer should access the current filename and write the desired data.

This method will contain a majority of the implementation for a new writer class.

## Syntax

*Result* = *Obj* -> [IDLitWriter::]SetData(*Data*)

## Return Value

Returns a 1 if successful, or a 0 if the initialization failed.

## Arguments

### Data

A data object that contains the information to be written.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWriter::SetFilename

The IDLitWriter::SetFilename procedure method is called by the system to set the current filename associated with this writer. Due to the automated nature of the file writer system, filenames can be associated with a file writer and then the file can be written at a later time.

## Syntax

*Obj* -> [IDLitWriter::]SetFilename, *Filename*

## Arguments

### Filename

A string that contains the filename associated with this writer.

## Keywords

None

## Version History

Introduced: 6.0

# IDLitWriter::SetProperty

The IDLitWriter::SetProperty procedure method sets the value of an IDLitWriter property, and should be called by the subclass' SetProperty method. This method also calls the superclass' SetProperty method.

## Syntax

*Obj* -> [IDLitWriter::]SetProperty[, *PROPERTY*=*value*]

## Arguments

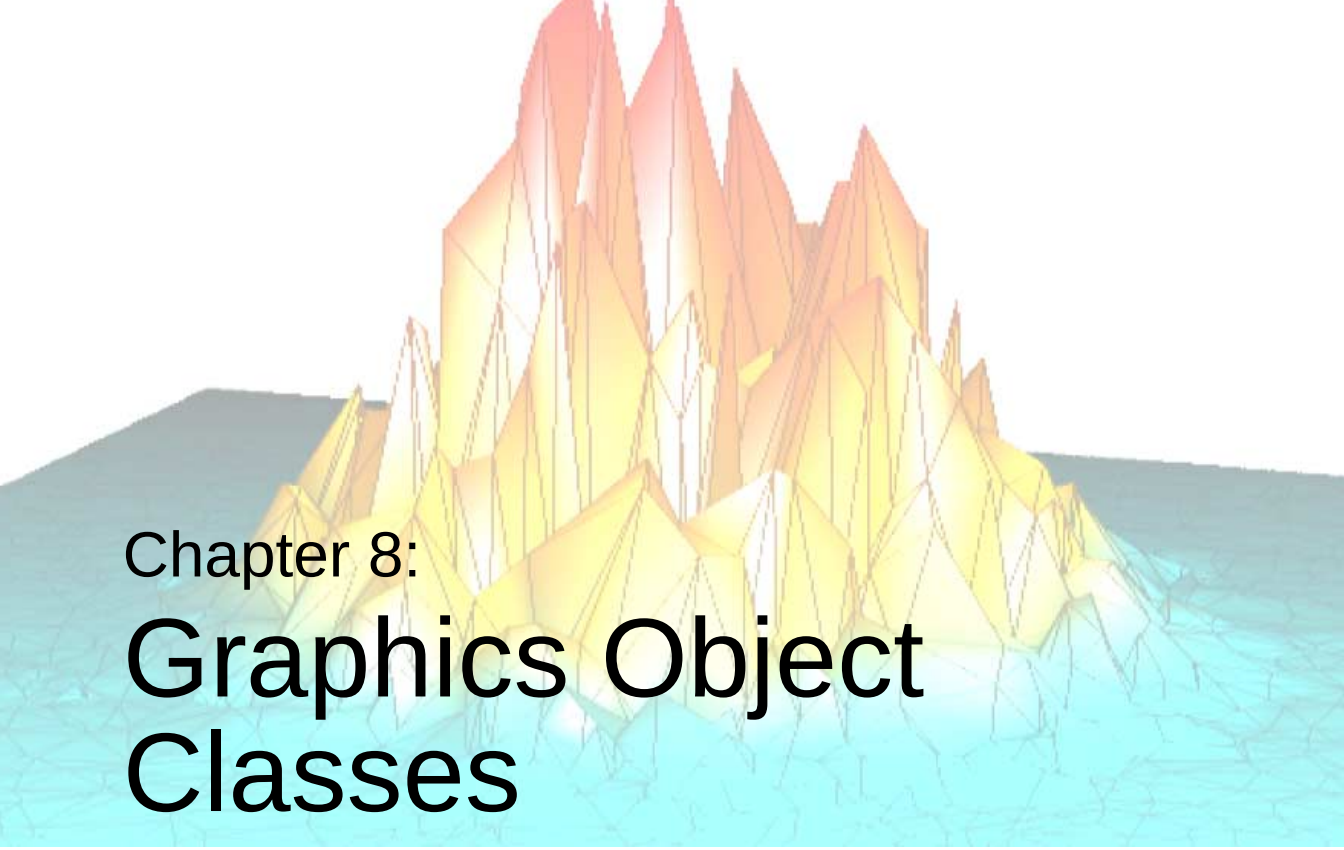
None

## Keywords

Any property listed under "IDLitReader Properties" on page 2956 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 6.0



# Chapter 8: Graphics Object Classes

This chapter describes IDL's built-in graphics class library.

# IDLgrAxis

An axis object represents a single vector that may include a set of tick marks, tick labels, and a title.

An IDLgrAxis object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

IDLitComponent

## Creation

See "IDLgrAxis::Init" on page 3165.

## Properties

Objects of this class have the following properties. See "IDLgrAxis Properties" on page 3140 for details on individual properties.

- ALL
- AM_PM
- CLIP_PLANES
- COLOR
- CRANGE
- DAYS_OF_WEEK
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- DIRECTION
- EXACT
- EXTEND
- GRIDSTYLE
- HIDE
- LOCATION
- LOG
- MAJOR
- MINOR
- MONTHS
- NOTEXT
- PALETTE
- PARENT
- RANGE
- REGISTER_PROPERTIES
- SUBTICKLEN
- TEXTALIGNMENTS

- TEXTBASELINE
- TEXTUPDIR
- TICKDIR
- TICKFRMTDATA
- TICKLAYOUT
- TICKTEXT
- TICKVALUES
- USE_TEXT_COLOR
- XRANGE
- YRANGE
- ZRANGE
- TEXTPOS
- THICK
- TICKFORMAT
- TICKINTERVAL
- TICKLEN
- TICKUNITS
- TITLE
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrAxis::Cleanup
- IDLgrAxis::GetCTM
- IDLgrAxis::GetProperty
- IDLgrAxis::Init
- IDLgrAxis::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrAxis Properties

IDLgrAxis objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrAxis::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrAxis::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrAxis::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## AM_PM

A string array of 2 names to be used for the names of the AM and PM string when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the TICKFORMAT property.

| | | | |
|---|---|---|---|
| **Property Type** | String array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## CLIP_PLANES

A 4 by *n* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A*x* + B*y* + C*z* + D = 0. Portions of this object that fall in the half space A*x* + B*y* + C*z* + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

The color to be used as the foreground color for this axis. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0].

| **Property Type** | Color | | |
|---|---|---|---|
| **Name String** | Color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CRANGE

A double-precision floating-point vector of the form [minval, maxval] that will contain the actual full range of the axis. This range may not exactly match the requested range provided via the RANGE property in the Init and SetProperty

methods. Adjustments may have been made to round to the nearest even tick interval or to accommodate the EXTEND property.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DAYS_OF_WEEK

A string array of 7 names to be used for the names of the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the TICKFORMAT property.

| **Property Type** | String array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DIRECTION

An integer value that specifies which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis. Specifying this property is the same as specifying the optional *Direction* argument.

This property is registered as an enumerated list, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Direction | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## EXACT

A Boolean value that determines whether to force the axis range to be exactly as specified. If this property is not set, the range may be lengthened or shortened slightly to allow for evenly spaced tick marks.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | Use exact axis range | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## EXTEND

A Boolean value that determines whether to extend the axis slightly beyond the specified range. This can be useful when you specify the axis range based on the minimum and maximum data values, but do not want the graphic to extend all the way to the end of the axis.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | Extend axis | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## GRIDSTYLE

An integer or two-element vector that indicates the line style that should be used to draw the axis' tick marks. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the GRIDSTYLE property equal to one of the following integer values:

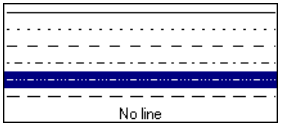
- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `GRIDSTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as a Linestyle drop-down list, with the following options:



| **Property Type** | Linestyle | | |
|---|---|---|---|
| **Name String** | Line style | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value indicating whether this object should be drawn. Options:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In property sheets, this property appears as an enumerated list, with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LOCATION

A two- or three-element floating-point vector of the form [*x*, *y*] or [*x*, *y*, *z*] to specify the coordinate through which the axis should pass. The default is [0, 0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LOG

A Boolean value that indicates whether the axis is logarithmic.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | Use logarithmic axis | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## MAJOR

An integer representing the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | Number of major ticks | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | Number of minor ticks | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## MONTHS

A string array of 12 names to be used for the names of the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the TICKFORMAT property.

| | | | |
|---|---|---|---|
| **Property Type** | String array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## NOTEXT

A Boolean value indicating whether the tick labels and the axis title should be drawn.

- 0 = Draw tick labels and axis title (the default).
- 1 = Do not draw tick labels and axis title.

In a property sheet, this property appears as an enumerated list. Options:

- True = Draw tick labels and axis title (the default).
- False = Do not draw the tick labels and axis title.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Text show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PALETTE

The object reference of a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## RANGE

A two-element floating-point vector containing the minimum and maximum data values covered by the axis. The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Minor tick length | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TEXTALIGNMENTS

A two-element floating-point vector, [*horizontal*, *vertical*], specifying the horizontal and vertical alignments for the tick text. Each alignment value should be a value between 0.0 and 1.0. For horizontal alignment, 0.0 left-justifies the text; 1.0 right-justifies the text.

For vertical alignment, 0.0 bottom-justifies the text, 1.0 top-justifies the text. The defaults are as follows:

- *X*-Axis: [0.5, 1.0] (centered horizontally, top-justified vertically)
- Y-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)
- Z-Axis: [1.0, 0.5] (right-justified horizontally, centered vertically)

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TEXTBASELINE

A two- or three-element floating-point vector describing the direction in which the baseline of the tick text is to be oriented. Use this property in conjunction with the TEXTUPDIR property to specify the plane on which the tick text lies. The default is [1,0,0].

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TEXTPOS

An integer that indicates on which side of the axis to draw the tick text labels. The table below describes the placement of the tick text with each setting.

| Axis | TEXTPOS = 0 | TEXTPOS = 1 |
|---|---|---|
| **X** | Tick text will be drawn *below* the X axis, where *below* is defined as being toward the direction of the negative Y axis (this is the default). | Tick text will be drawn *above* the X axis, where *above* is described as being toward the direction of the positive Y axis. |

*Table 8-1: Values for the TEXTPOS property*

| Axis | TEXTPOS = 0 | TEXTPOS = 1 |
|---|---|---|
| **Y** | Tick text will be drawn to the *left* of the Y Axis, where *left* is defined as being toward the direction of the negative X axis (this is the default). | Tick text will be drawn to the *right* of the Y axis, where *right* is defined as being toward the direction of the positive X axis. |
| **Z** | Tick text will be drawn to the *left* of the Z axis, where *left* is defined as being toward the direction of the negative X axis (this is the default). | Tick text will be drawn to the *right* of the Z axis, where *right* is defined as being toward the direction of the positive X axis. |

*Table 8-1: Values for the TEXTPOS property*

In a property sheet, this property appears as an enumerated list. Options:

- Below/left: Text will be drawn below the axis and to the left.
- Above/right: Text will be drawn above the axis and to the right.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Text position | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TEXTUPDIR

A two- or three-element floating-point vector describing the direction in which the up-vector of the tick text is to be oriented. Use this property in conjunction with the TEXTBASELINE property to specify the plane on which the tick text lies. TEXTUPDIR should be orthogonal to TEXTBASELINE. The default is as follows:

- *X*-Axis: [0, 1, 0]
- *Y*-Axis: [0, 1, 0]
- *Z*-Axis: [0, 0, 1]

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## THICK

A floating-point value in points between 1.0 and 10.0 that specifies the line thickness used to draw the axis. The default is 1.0 points.

In a property sheet, this property appears as a Thickness drop-down list with the following options:

| **Property Type** | Thickness | | |
|---|---|---|---|
| **Name String** | Line thickness | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TICKDIR

An integer value of zero or one to indicate the tick mark direction.

| Axis | TICKDIR = 0 | TICKDIR = 1 |
|---|---|---|
| X | Tick marks will be drawn above the X axis, in the direction of the positive Y axis (this is the default). | Tick marks will be drawn below the X axis. |
| Y | Tick marks will be drawn to the right of the Y axis, in the direction of the positive X axis (this is the default). | Tick marks will be drawn to the left of the Y axis. |
| Z | Tick marks will be drawn to the right the Z axis, in the direction of the positive X axis (this is the default). | Tick marks will be drawn to the left of the Z axis. |

*Table 8-2: Tick Mark Direction Values*

In a property sheet, this property appears as an enumerated list, with the following options:

- Right/above: Tick marks will be drawn above the axis and to the right.
- Left/below: Tick marks will be drawn below the axis and to the left.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Tick direction | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TICKFORMAT

A string, or an array of strings, in which each string represents a format string or the name of a function to be used to format the tick mark labels. If an array is provided, each string corresponds to a level of the axis. (The TICKUNITS property determines the number of levels for an axis.) If the number of strings stored in this property is one, GetProperty returns a scalar string, otherwise GetProperty returns an array of strings.

If the string begins with an open parenthesis, it is treated as a standard format string. (See "Format Codes" in Chapter 10 of the *Building IDL Applications* manual.)

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels.

### If TICKUNITS are not specified:

- The callback function is called with three parameters: *Axis*, *Index*, and *Value*, where:
- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis
- *Index* is the tick mark index (indices start at 0)
- *Value* is the data value at the tick mark (a double-precision floating point value)

### If TICKUNITS are specified:

The callback function is called with four parameters: *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled. (Level indices start at 0.)

Used with the LABEL_DATE function, this property can easily create axes with date/time labels.

| **Property Type** | String or string array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TICKFRMTDATA

A value of any type that will be passed via the DATA property to the user-supplied formatting function specified via the TICKFORMAT property, if any. By default, this value is 0, indicating that the DATA property will not be set (and furthermore, need not be supported by the user-supplied function.)

**Note**

TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrAxis::GetProperty method.

| **Property Type** | Scalar of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** | **Set:** | **Init:** | **Registered:** No |

## TICKINTERVAL

A floating-point scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis RANGE and the number of major tick marks (MAJOR). This property takes precedence over MAJOR.

For example, if TICKUNITS=['S','H','D'], and TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Tick interval | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TICKLAYOUT

An integer scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

**Note**

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

In a property sheet, this property appears as an enumerated list with the following options:

- Axis plus labels: Same as the 0 value above.
- Labels only: Same as the 1 value above.
- Box style: Same as the 2 value above.

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Tick layout | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Major tick length | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TICKTEXT

An object reference to a single instance of the IDLgrText object class (with multiple strings) or a vector of instances of the IDLgrText object class (one per major tick) to specify the annotations to be assigned to the tickmarks. By default, with TICKTEXT set equal to a null object, IDL computes the tick labels based on major tick values. The positions of the provided text objects may be overwritten; position is determined according to tick mark location. The tickmark text will have the same color as the IDLgrAxis object, regardless of the color specified by the COLOR property of the IDLgrText object or objects, unless the USE_TEXT_COLOR property is specified.

**Note**

If IDL computes the tick labels, the text object it creates will be destroyed automatically when the axis object is destroyed, even if you have altered the properties of the text object. If you create your own text object containing tickmark text, however, it will *not* be destroyed automatically.

| **Property Type** | Object reference or string vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TICKUNITS

A string (or a vector of strings) indicating the units to be used for axis tick labeling. If the number of levels in the axis is one, GetProperty returns a scalar string, otherwise GetProperty returns an array of strings.

If more than one unit is provided, the axis will be drawn in multiple levels, one level per unit.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- ""- Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the "Numeric" unit. This is the default setting.

If any of the time units are utilized, then the tick values are interpreted as Julian date/time values. Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

**Note**

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000hidd, respectively.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | STRING | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TICKVALUES

A floating-point vector of data values representing the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the

axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TITLE

An object reference to an instance of the IDLgrText object class that specifies the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location. The title will have the same color as the IDLgrAxis object, regardless of the color specified by the COLOR property of the IDLgrText object, unless the USE_TEXT_COLOR property is specified.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## USE_TEXT_COLOR

A Boolean value that indicates whether, for the tick text and/or title of the axis, the color property values set for the given IDLgrText objects are to be used to draw those text items. By default, this value is zero, indicating that the color properties of the IDLgrText objects will be ignored, and that the COLOR property for the axis object will be used for these text items instead.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, [$s_0$, $s_1$], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** | **Set:** | **Init:** | **Registered:** No |

# IDLgrAxis::Cleanup

The IDLgrAxis::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrAxis::]Cleanup(*Only in subclass' Cleanup method.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrAxis::GetCTM

The IDLgrAxis::GetCTM function method returns the graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrAxis::]GetCTM([, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref*])

## Return Value

Returns the 4 x 4 double-precision floating-point graphics transform matrix.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the axis object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrAxis::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrAxis::GetProperty

The IDLgrAxis::GetProperty procedure method retrieves the value of a property or group of properties for the axis.

## Syntax

*Obj* -> [IDLgrAxis::]GetProperty [, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrAxis Properties” on page 3140 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 5.0

# IDLgrAxis::Init

The IDLgrAxis::Init function method initializes an axis object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

# Syntax

*Obj* = OBJ_NEW('IDLgrAxis' [, *Direction*] [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLgrAxis::]Init([*Direction*] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

# Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

# Arguments

## Direction

An integer value specifying which axis is being created. Specify 0 (zero) to create an X axis, 1 (one) to create a Y axis, or 2 to create a Z axis.

# Keywords

Any property listed under "IDLgrAxis Properties" on page 3140 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

# IDLgrAxis::SetProperty

The IDLgrAxis::SetProperty procedure method sets the value of a property or group of properties for the axis.

## Syntax

*Obj* -> [IDLgrAxis::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrAxis Properties” on page 3140 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrBuffer

An IDLgrBuffer object is an in-memory, off-screen destination object. Object trees can be drawn to instances of the IDLgrBuffer object and the resulting image can be retrieved from the buffer using the Read() method. The off-screen representation avoids dithering artifacts by providing a full-resolution buffer for objects using either the RGB or Color Index color models.

**Note**

Objects or subclasses of this type can not be saved or restored.

## Superclasses

IDLitComponent

## Creation

See “IDLgrBuffer::Init” on page 3186.

## Properties

Objects of this class have the following properties. See “IDLgrBuffer Properties” on page 3170 for details on individual properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- GRAPHICS_TREE
- IMAGE_DATA
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS

- UNITS
- ZBUFFER_DATA

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrBuffer::Cleanup
- IDLgrBuffer::Draw
- IDLgrBuffer::Erase
- IDLgrBuffer::GetContiguousPixels
- IDLgrBuffer::GetDeviceInfo
- IDLgrBuffer::GetFontnames
- IDLgrBuffer::GetProperty
- IDLgrBuffer::GetTextDimensions
- IDLgrBuffer::Init
- IDLgrBuffer::PickData
- IDLgrBuffer::Read
- IDLgrBuffer::Select
- IDLgrBuffer::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrBuffer Properties

IDLgrBuffer objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrBuffer::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrBuffer::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrBuffer::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object (except IMAGE_DATA and ZBUFFER_DATA).

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## COLOR_MODEL

A Boolean value that determines the color model to be used for the buffer:

- 0 = RGB (default)
- 1 = Color Index

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Color model | | |
| **Get:** Yes | **Set:** | **Init:** Yes | **Registered:** Yes |

## DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the dimensions of the buffer in units specified by the UNITS property. The default is [640,480].

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## IMAGE_DATA

A byte array representing the image that is currently rendered within the buffer. If the buffer uses an RGB color model, the returned array will have dimensions (3, *xdim*, *ydim*). If the window object uses an indexed color model, the returned array will have dimensions (*xdim*, *ydim*).

| **Property Type** | Byte array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## N_COLORS

An integer that determines the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

| **Property Type** | INTEGER | | |
|---|---|---|---|
| **Name String** | Number of colors | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values to be loaded into the buffer's color lookup table.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## QUALITY

An integer that indicates the rendering quality at which graphics are to be drawn to the buffer. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium

- High

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Draw quality | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RESOLUTION

A two-element floating-point vector of the form [*xres*, *yres*] that specifies the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: [0.035277778, 0.035277778] (72 DPI).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Resolution | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## SCREEN_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the maximum allowed dimensions (measured in device units) for the buffer object.

**Note**

The maximum buffer dimension size is always 2048 by 2048.

| | | | |
|---|---|---|---|
| **Property Type** | Integer vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to 1600 x 1200

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZBUFFER_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrBuffer::Cleanup

The IDLgrBuffer::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrBuffer::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrBuffer::Draw

The IDLgrBuffer::Draw procedure method draws the given picture to this graphics destination.

**Note**

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

# Syntax

*Obj* -> [IDLgrBuffer::]Draw [, *Picture*] [, CREATE_INSTANCE={1 | 2}] [, /DRAW_INSTANCE]

# Arguments

## Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object) or scene (an instance of an IDLgrScene object) to be drawn.

# Keywords

## CREATE_INSTANCE

Set this keyword equal to one to specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

## DRAW_INSTANCE

Set this keyword to specify that this scene, viewgroup, or view is the changing part of the drawing. It is overlaid on the result of the most recent CREATE_INSTANCE draw.

# Version History

Introduced: 5.0

# IDLgrBuffer::Erase

The IDLgrBuffer::Erase procedure method erases this graphics destination.

## Syntax

*Obj* -> [IDLgrBuffer::]Erase [, COLOR=*index or RGB vector*]

## Arguments

None

## Keywords

### COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as an RGB vector.

## Version History

Introduced: 5.0

# IDLgrBuffer::GetContiguousPixels

The IDLgrBuffer::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj -> GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

## Syntax

*Result* = *Obj* -> [IDLgrBuffer::]GetContiguousPixels()

## Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrBuffer::GetDeviceInfo

The IDLgrBuffer::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

## Syntax

*Obj* -> [IDLgrBuffer::]GetDeviceInfo [, ALL=*variable*]
[, MAX_NUM_CLIP_PLANES=*variable*]
[, MAX_TEXTURE_DIMENSIONS=*variable*]
[, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
[, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

## Arguments

None

## Keywords

### ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

### MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

### MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two-element integer array that specifies the maximum texture size supported by the device.

### MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two-element integer array that specifies the maximum size of a graphics display supported by the device.

### NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

### NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

**Note**

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

### VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

### VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

## Version History

Introduced: 5.0

MAX_NUM_CLIP_PLANES keyword: 5.6

# IDLgrBuffer::GetFontnames

The IDLgrBuffer::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned. See Appendix H, "Fonts" for more information.

## Syntax

*Result* = *Obj* -> [IDLgrBuffer::]GetFontnames( *FamilyName*[, IDL_FONTS={0 | 1 | 2 }] [, STYLES=*string*] )

## Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

## Arguments

### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

## Keywords

### IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

Introduced: 5.0

# IDLgrBuffer::GetProperty

The IDLgrBuffer::GetProperty procedure method retrieves the value of a property or group of properties for the buffer.

## Syntax

*Obj* -> [IDLgrBuffer::]GetProperty[, *PROPERTY*=*variable*]

## Keywords

Any property listed under “IDLgrBuffer Properties” on page 3170 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s super-class.

## Version History

Introduced: 5.0

# IDLgrBuffer::GetTextDimensions

The IDLgrBuffer::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

## Syntax

*Result* = *Obj* ->[IDLgrBuffer::]GetTextDimensions( *TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*] )

## Return Value

Returns the dimensions of a text or axis object that will be rendered in a window.

## Arguments

### TextObj

The object reference to a text or axis object for which text dimensions are requested.

## Keywords

### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If

IDLgrBuffer::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## Version History

Introduced: 5.0

# IDLgrBuffer::Init

The IDLgrBuffer::Init function method initializes the buffer object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrBuffer' [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLgrBuffer::]Init([*PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrBuffer Properties" on page 3170 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

# IDLgrBuffer::PickData

The IDLgrBuffer::PickData function method maps a point in the two-dimensional device space of the buffer to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

## Syntax

*Result* = *Obj* -> [IDLgrBuffer::]PickData( *View*, *Object*, *Location*, *XYZLocation* [, DIMENSIONS=*[width,height]*][, PATH=*objref(s)*] [, PICK_STATUS=*variable*])

## Return Value

Returns one if the specified location in the buffer's device space "hits" a graphic object, or zero otherwise.

## Arguments

### View

The object reference of an IDLgrView object that contains the object being picked.

### Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

### Location

A two-element vector [*x*, *y*] specifying the location in the buffer's device space of the point to pick data from.

### XYZLocation

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

**Note**

If the atomic graphic object specified as the target has been transformed using either the LOCATION or DIMENSIONS properties (this is only possible with

IDLgrAxis, IDLgrImage, and IDLgrText objects), these transformations will *not* be included in the data coordinates returned by the PickData function. This means that you may need to re-apply the transformation accomplished by specifying LOCATION or DIMENSIONS once you have retrieved the data coordinates with PickData. This situation does not occur if you transform the axis, text, or image object using the [XYZ]COORD_CONV properties.

# Keywords

## DIMENSIONS

Set this keyword to a two-element array [*w, h*] to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates [*x, y*] specified in the *Location* argument, and will occupy the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))
```

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions [*3, w, h*].

## PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## PICK_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK_STATUS will be a scalar value exactly matching the *Result* of the method call. If the DIMENSIONS keyword is set, the PICK_STATUS variable will be an array matching the dimensions

of the pick box. Each value in the PICK_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

| Value | Description |
|---|---|
| -1 | The pixel falls outside of the window’s viewport. |
| 0 | No graphic object is “hit” at that pixel location. |
| 1 | A graphic object is “hit” at that pixel location. |

*Table 8-3: PICK_STATUS Keyword Values*

## Version History

Introduced: 5.0

PICK_STATUS keyword: 5.6

# IDLgrBuffer::Read

The IDLgrBuffer::Read function method reads an image from a buffer. The returned value is an instance of the IDLgrImage object class.

## Syntax

*Result* = *Obj* -> [IDLgrBuffer::]Read()

## Return Value

Returns an instance of the IDLgrImage object class.

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrBuffer::Select

The IDLgrBuffer::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

**Note**

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

## Syntax

*Result* = *Obj* -> [IDLgrBuffer::]Select(*Picture, XY* [, DIMENSIONS=*[width, height]*] [, /ORDER] [, UNITS={0 | 1 | 2 | 3}])

## Return Value

Returns a list of objects selected at a specified location.

## Arguments

### Picture

The view, viewgroup, or scene (an instance of the IDLgrView, IDLgrViewgroup, or IDLgrScene class) whose children are among the candidates for selection.

If the first argument is a scene or viewgroup, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the first object drawn will appear at a lower index in the list. (The ORDER keyword can be used to change this behavior.)

### XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels.

# Keywords

## DIMENSIONS

Set this keyword to a two-element array [*w*, *h*] to specify that the selection box will have a width *w* and a height *h*, and will be centered about the coordinates [*x*, *y*] specified in the *XY* argument. The box occupies the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/1), y+(h/2))
```

Any object which intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

## ORDER

Set this keyword to control how objects that are the same distance from the viewer are ordered in the selection list. If ORDER=0 (the default), the order of objects in the selection list will be the same as the order in which the objects are drawn. If ORDER=1, the order of objects in the selection list will be the reverse of the order in which they are drawn. This keyword has no affect on the ordering of objects that are not at the same distance from the viewer.

**Tip**

If you are using DEPTH_TEST_FUNCTION=4 (“less than or equal”) on your graphics objects, set ORDER=1 to return objects at the same depth in the order in which they appear visually.

## UNITS

Set this keyword to indicate the units of measure. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the graphics destination.

# Version History

Introduced: 5.0

# IDLgrBuffer::SetProperty

The IDLgrBuffer::SetProperty procedure method sets the value of a property or group of properties for the buffer.

## Syntax

*Obj* -> [IDLgrBuffer::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrBuffer Properties” on page 3170 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrClipboard

An IDLgrClipboard object will send Object Graphics output to the operating system native clipboard in bitmap format. The format of bitmaps sent to the clipboard is operating system dependent: output is stored as a device-independent bitmap under Windows and as an Encapsulated PostScript (EPS) image under UNIX.

**Note**

Objects or subclasses of this type can not be saved or restored.

## Superclasses

IDLitComponent

## Creation

See "IDLgrClipboard::Init" on page 3215.

## Properties

Objects of this class have the following properties. See "IDLgrClipboard Properties" on page 3197 for details on individual properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- GRAPHICS_TREE
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS
- UNITS

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrClipboard::Cleanup
- IDLgrClipboard::Draw
- IDLgrClipboard::GetContiguousPixels
- IDLgrClipboard::GetDeviceInfo
- IDLgrClipboard::GetFontnames
- IDLgrClipboard::GetProperty
- IDLgrClipboard::GetTextDimensions
- IDLgrClipboard::Init
- IDLgrClipboard::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.1

# IDLgrClipboard Properties

IDLgrClipboard objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrClipboard::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrClipboard::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrClipboard::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure that contains the values of all of the retrievable properties associated with this object.

| | | | |
|---|---|---|---|
| **Property Type** | Anonymous structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## COLOR_MODEL

An integer value that determines whether to use the indexed color model for the clipboard buffer:

- 0 = RGB (default)
- 1 = Color Index

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Color model | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## DIMENSIONS

A two-element integer vector of the form [*width, height*] to specify the dimensions of the clipboard buffer in units specified by the UNITS property. The default is [640,480].

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphic tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## N_COLORS

An integer value that determines the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Color Index.

| **Property Type** | INTEGER | | |
|---|---|---|---|
| **Name String** | Number of colors | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values that are to be loaded into the clipboard buffer's color lookup table.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## QUALITY

An integer indicating the rendering quality at which graphics are to be drawn to the clipboard buffer. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Draw quality | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RESOLUTION

A two-element floating-point vector of the form [*xres*, *yres*] specifying the device resolution in centimeters per pixel. This value is stored in double precision. The default value is: [0.035277778, 0.035277778] (72 DPI).

**Note**

To match screen rendering on an IDLgrClipboard object, the following properties should be matched between the devices: DIMENSIONS, UNITS, RESOLUTION, COLOR_MODEL and N_COLORS.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Resolution | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## SCREEN_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] that specifies the maximum allowed dimensions (measured in device units) for the clipboard object.

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters

- 3 = Normalized (relative to 1600 x 1200)

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLgrClipboard::Cleanup

The IDLgrClipboard::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj->* [IDLgrClipboard::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrClipboard::Draw

The IDLgrClipboard::Draw procedure method draws the given picture to this graphics destination.

**Note**

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

## Syntax

*Obj* -> [IDLgrClipboard::]Draw [, *Picture*] [, FILENAME=*string*] [, POSTSCRIPT=*value*] [, VECTOR={ 0 | 1 } ]

## Arguments

### Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object) or scene (an instance of an IDLgrScene object) to be drawn.

## Keywords

### FILENAME

Set this keyword to a string representing the name of a file to which the output should be written. By default, this keyword is the null string, indicating that the output is written to the clipboard.

### POSTSCRIPT

Set this keyword to a nonzero value to indicate that the generated output should be in PostScript format. By default, the generated output is in Windows Enhanced Metafile Format on Windows platforms and PostScript on UNIX platforms.

### VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values include:

- 0 = Bitmap (default)
- 1 = Vector

If VECTOR = 0 (Bitmap), the Draw method renders the scene to a buffer and then copies the buffer to the printer in bitmap format. The bitmap retains the quality of the original image, but the user cannot scale the bitmap effectively on all devices.

If VECTOR = 1 (Vector), the Draw method renders the scene using simple vector operations that result in a representation of the Scene that is scalable to the printer. The vector representation does not retain all the attributes of the original image, however, a user can effectively scale it on other devices. On Windows, the representation is the Windows Enhanced Metafile (EMF). On UNIX platforms, the representation is PostScript.

## Examples

This example demonstrates the process of copying the contents of an IDL graphics display object (a buffer or a window) to the system clipboard, where it becomes available for pasting into another application. The example also uses the IDLgrClipboard::Draw method to create an encapsulated PostScript file in the current directory.

```
PRO SendingPlotToClipboard

; Determine the path to the "damp_sn2.dat" file.
signalFile = FILEPATH('damp_sn2.dat', $
   SUBDIRECTORY = ['examples', 'data'])

# IDLgrClipboard::GetContiguousPixels

The IDLgrClipboard::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj -> GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

## Syntax

*Result* = *Obj* ->[IDLgrClipboard::]GetContiguousPixels()

## Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrClipboard::GetDeviceInfo

The IDLgrClipboard::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

## Syntax

*Obj* -> [IDLgrClipboard::]GetDeviceInfo [, ALL=*variable*]
[, MAX_NUM_CLIP_PLANES=*variable*]
[, MAX_TEXTURE_DIMENSIONS=*variable*]
[, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
[, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

## Arguments

None

## Keywords

### ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

### MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

### MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

### MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

### NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

### NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

**Note**

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

### VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

### VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

## Version History

Introduced: 5.1

MAX_NUM_CLIP_PLANES keyword: 5.6

# IDLgrClipboard::GetFontnames

The IDLgrClipboard::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix H, "Fonts" for more information.

## Syntax

*Result* = *Obj* -> [IDLgrClipboard::]GetFontnames( *FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*] )

## Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

## Arguments

### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

## Keywords

### IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

Introduced: 5.1

# IDLgrClipboard::GetProperty

The IDLgrClipboard::GetProperty procedure method retrieves the value of a property or group of properties for the clipboard buffer.

## Syntax

*Obj* -> [IDLgrClipboard::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrClipboard Properties” on page 3197 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.1

# IDLgrClipboard::GetTextDimensions

The IDLgrClipboard::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in the clipboard buffer. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

## Syntax

*Result* = *Obj* ->[IDLgrClipboard::]GetTextDimensions( *TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*] )

## Return Value

Returns the dimensions of a text or axis object that will be rendered in the clipboard buffer.

## Arguments

### TextObj

The object reference to a text or axis object for which the text dimensions are requested.

## Keywords

### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If

this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrClipboard::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## Version History

Introduced: 5.1

# IDLgrClipboard::Init

The IDLgrClipboard::Init function method initializes the clipboard object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrClipboard' [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrClipboard::]Init([*PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrClipboard Properties" on page 3197 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.1

# IDLgrClipboard::SetProperty

The IDLgrClipboard::SetProperty procedure method sets the value of a property or group of properties for the clipboard buffer.

## Syntax

*Obj* -> [IDLgrClipboard::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrClipboard Properties” on page 3197 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.1

# IDLgrColorbar

The IDLgrColorbar object consists of a color-ramp with an optional framing box and annotation axis. The object can be horizontal or vertical.

An IDLgrColorbar object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrcolorbar__define.pro` in the `lib` subdirectory of the IDL distribution.

## Superclasses

IDLgrModel

IDLitComponent

## Creation

See "IDLgrColorbar::Init" on page 3235.

## Properties

Objects of this class have the following properties. See "IDLgrColorbar Properties" on page 3221 for details on individual properties.

- ALL
- BLUE_VALUES
- COLOR
- DIMENSIONS
- GREEN_VALUES
- HIDE
- MAJOR
- MINOR
- PALETTE
- PARENT

- RED_VALUES
- SHOW_AXIS
- SHOW_OUTLINE
- SUBTICKLEN
- THICK
- THREED
- TICKFORMAT
- TICKFRMTDATA
- TICKLEN
- TICKTEXT
- TICKVALUES
- TITLE
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrColorbar::Cleanup
- IDLgrColorbar::ComputeDimensions
- IDLgrColorbar::GetProperty
- IDLgrColorbar::Init
- IDLgrColorbar::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.1

# IDLgrColorbar Properties

IDLgrColorbar objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrColorbar::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrColorbar::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrColorbar::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure that contains the values of all of the retrievable properties associated with this object.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## BLUE_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the aBlue argument to the IDLgrColorbar::Init method.

| | | | |
|---|---|---|---|
| **Property Type** | Byte vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

The color to be used as the foreground color for the axis and outline box. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0].

| **Property Type** | Color | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DIMENSIONS

A two element integer vector [*dx*, *dy*] that specifies the size of the ramp display (not the axis) in pixels. If *dx* > *dy*, the colorbar is drawn horizontally with the axis placed below or above the ramp box depending on the value of the SHOW_AXIS property. If *dx* < *dy*, the colorbar is drawn vertically with the axis placed to the right or left of the ramp box depending on the value of the SHOW_AXIS property. The default value is [16,256].

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GREEN_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the IDLgrColorbar::Init method.

| **Property Type** | Byte vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## HIDE

A Boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)

- 1 = Do not draw graphic

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## MAJOR

An integer that represents the number of major tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MAJOR equal to zero suppresses major tickmarks entirely.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## MINOR

An integer representing the number of minor tick marks. The default is -1, specifying that IDL will compute the number of tickmarks. Setting MINOR equal to zero suppresses minor tickmarks entirely.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PALETTE

An object reference to an instance of the IDLgrPalette object class. If this property is a valid object reference, the colors within the IDLgrPalette are used to specify the colors for the colorbar.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PARENT

An object reference to the object that contains this colorbar.

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## RED_VALUES

A byte vector that contains the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the IDLgrColorbar::Init method.

| | | | |
|---|---|---|---|
| **Property Type** | Byte vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHOW_AXIS

An integer value that indicates whether the axis should be drawn:

- 0 = Do not display axis (the default)
- 1 = Display axis on left side or below the color ramp
- 2 = Display axis on right side or above the color ramp

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHOW_OUTLINE

A Boolean value indicating whether the colorbar bounds should be outlined:

- 0 = Do not display outline (the default)

- 1 = Display outline

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SUBTICKLEN

A floating-point scale ratio specifying the length of minor tick marks relative to the length of major tick marks. The default is 0.5, specifying that the minor tick mark is one-half the length of the major tick mark.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness used to draw the axis and box outline, in points. The default is 1.0 points.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## THREED

A Boolean value that determines whether to create the colorbar as a graphic object that can be fully transformed in three dimensions on initialization. By default, the colorbar always faces the viewer and is drawn at z=0.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** | **Init:** Yes | **Registered:** No |

## TICKFORMAT

Either a standard IDL format string (see *"Format Codes"* in Chapter 10 of the *Building IDL Applications* manual for details on format codes) or a string containing the name of a user-supplied function that returns a string to be used to format the axis tick mark labels. The function should accept integer arguments for the direction of the axis, the index of the tick mark, and the value of the tick mark, and should return a string to be used as the tick mark's label. The function may optionally accept a keyword called DATA, which will be automatically set to the TICKFRMTDATA value. The default TICKFORMAT is '', the null string, which indicates that IDL will determine the appropriate format for each value.

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TICKFRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the TICKFORMAT property, if any. By default, this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function). Note that TICKFRMTDATA will not be included in the structure returned via the ALL property to the IDLgrColorbar::GetProperty method.

| **Property Type** | Scalar of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TICKLEN

A floating-point value that specifies the length of each major tick mark, measured in data units. The recommended, and default, tick mark length is 0.2. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TICKTEXT

An object reference to either a single instance of the IDLgrText object class (with multiple strings) or to a vector of instances of the IDLgrText object class (each with a single string) that specifies the annotations to be assigned to the tick marks. By default, TICKTEXT is set to the NULL object, which indicates that IDL will compute tick annotations based upon the major tick values. The positions and orientation of the provided text object(s) may be overwritten by the colorbar.

| **Property Type** | Object reference or object reference vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TICKVALUES

A floating-point vector of data values that represent the values at each tick mark. If TICKVALUES is set to 0, the default, IDL computes the tick values based on the axis range and the number of major ticks. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the axis. The default is the null object, specifying that no title is drawn. The title will be centered along the axis, even if the text object itself has an associated location.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] specifying the range of the *x* data coordinates covered by the colorbar.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that converts Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the colorbar.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, [$s_0$, $s_1$], of scaling factors that converts Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] specifying the range of the *Z* data coordinates covered by the colorbar.

**Note**

Until the colorbar is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the ComputeDimensions method on the colorbar object to get the data dimensions of the colorbar prior to a draw operation.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrColorbar::Cleanup

The IDLgrColorbar::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY,*Obj*

or

*Obj* -> [IDLgrColorbar::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrColorbar::ComputeDimensions

The IDLgrColorbar::ComputeDimensions function method retrieves the dimensions of a colorbar object for the given destination object. The result is a three-element double-precision floating-point vector [*xDim, yDim, zDim*] representing the dimensions of the colorbar object measured in data units.

## Syntax

*Result = Obj* ->[IDLgrColorbar::]ComputeDimensions( *DestinationObj* [, PATH=*objref(s)*] )

## Return Value

Returns the dimensions of a colorbar object for the given destination object.

## Arguments

### DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the colorbar are being requested.

## Keywords

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrColorbar::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## Version History

Introduced: 5.1

# IDLgrColorbar::GetProperty

The IDLgrColorbar::GetProperty procedure method retrieves the value of a property or group of properties for the colorbar.

## Syntax

*Obj* -> [IDLgrColorbar::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrColorbar Properties” on page 3221 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.1

# IDLgrColorbar::Init

The IDLgrColorbar::Init function method initializes the colorbar object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW( 'IDLgrColorbar' [, *aRed*, *aGreen*, *aBlue*] [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrColorbar::]Init([*aRed*, *aGreen*, *aBlue*] [, *PROPERTY*=*value*]) (*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### aRed

A vector containing the red values for the color palette. These values should be within the range of 0 < *Value* < 255. The number of elements comprising the *aRed* vector must not exceed 256.

### aGreen

A vector containing the green values for the color palette. These values should be within the range of 0 < *Value* < 255. The number of elements comprising the *aGreen* vector must not exceed 256.

### aBlue

A vector containing the blue values for the color palette. These values should be within the range of 0 < *Value* < 255. The number of elements comprising the *aBlue* vector must not exceed 256.

If *aRed*, *aGreen*, and *aBlue* are not provided, the color palette will default to a 256 entry greyscale ramp.

## Keywords

Any property listed under "IDLgrColorbar Properties" on page 3221 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.1

# IDLgrColorbar::SetProperty

The IDLgrColorbar::SetProperty procedure method sets the value of a property or group of properties for the colorbar.

## Syntax

*Obj* -> [IDLgrColorbar::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrColorbar Properties” on page 3221 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.1

# IDLgrContour

The IDLgrContour object draws a contour plot from data stored in a rectangular array or from a set of unstructured points. Both line contours and filled contour plots can be created.

An IDLgrContour object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

The object stores the following argument or property in double-precision if the DOUBLE_DATA property is specified, and in single-precision otherwise.

## Superclasses

IDLitComponent

## Creation

See “IDLgrContour::Init” on page 3273.

## Properties

Objects of this class have the following properties. See “IDLgrContour Properties” on page 3241 for details on individual properties.

- ALL
- ANISOTROPY
- C_FILL_PATTERN
- C_LABEL_NOGAPS
- C_LABEL_SHOW
- C_THICK
- C_USE_LABEL_ORIENTATION
- CLIP_PLANES
- DATA_VALUES
- DEPTH_OFFSET
- DEPTH_TEST_FUNCTION
- AM_PM
- C_COLOR
- C_LABEL_INTERVAL
- C_LABEL_OBJECTS
- C_LINESTYLE
- C_USE_LABEL_COLOR
- C_VALUE
- COLOR
- DAYS_OF_WEEK
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE

- DOUBLE_DATA
- DOUBLE_GEOM
- DOWNHILL
- FILL
- GEOM
- GEOMX
- GEOMY
- GEOMZ
- HIDE
- LABEL_FONT
- LABEL_FORMAT
- LABEL_FRMTDATA
- LABEL_UNITS
- MAX_VALUE
- MIN_VALUE
- MONTHS
- N_LEVELS
- PALETTE
- PARENT
- PLANAR
- POLYGONS
- REGISTER_PROPERTIES
- SHADE_RANGE
- SHADING
- TICKINTERVAL
- TICKLEN
- USE_TEXT_ALIGNMENTS
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrContour::AdjustLabelOffsets
- IDLgrContour::Cleanup
- IDLgrContour::GetCTM
- IDLgrContour::GetLabelInfo
- IDLgrContour::GetProperty
- IDLgrContour::Init
- IDLgrContour::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.1

# IDLgrContour Properties

IDLgrContour objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrContour::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrContour::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrContour::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## AM_PM

A string vector of two values indicating the names of the AM and PM strings when processing explicitly formatted dates (CAPA, CApA, and CapA format codes) with the LABEL_FORMAT property.

| | | | |
|---|---|---|---|
| **Property Type** | String vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ANISOTROPY

A three-element floating-point vector [*x*, *y*, *z*] that represents the multipliers to be applied to the internally computed correction factors along each axis that account for anisotropic geometry. Correcting for anisotropy is particularly important for the appropriate representations of downhill tickmarks.

By default, IDL will automatically compute correction factors for anisotropy based on the [XYZ] range of the contour geometry. If the geometry (as provided via the GEOMX, GEOMY, and GEOMZ keywords) falls within the range [*xmin*, *ymin*, *zmin*] to [*xmax*, *ymax*, *zmax*], then the default correction factors are computed as follows:

```
dx = xmax - xmin
dy = ymax - ymin
dz = zmax - zmin
; Get the maximum of the ranges:
maxRange = (dx > dy) > dz
IF (dx EQ 0) THEN xcorrection = 1.0 ELSE $
   xcorrection = maxRange / dx
IF (dy EQ 0) THEN ycorrection = 1.0 ELSE $
   ycorrection = maxRange / dy
IF (dz EQ 0) THEN zcorrection = 1.0 ELSE $
   zcorrection = maxRange / dz
```

This internally computed correction is then multiplied by the corresponding [*x, y, z*] values of the ANISOTROPY property. The default value for this property is [1,1,1]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Anistrophy | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## C_COLOR

A vector of colors that represents the colors to be applied at each contour level. If there are more contour levels than elements in this vector, the colors will be cyclically repeated. If C_COLOR is set to 0, all contour levels will be drawn in the color specified by the COLOR property (this is the default).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Colors | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## C_FILL_PATTERN

An array of IDLgrPattern objects that represent the patterns to be applied at each contour level if the FILL property is non-zero. If there are more contour levels than fill patterns, the patterns will be cyclically repeated. If this property is set to 0, all contour levels are filled with a solid color (this is the default).

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Fill patterns | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## C_LABEL_INTERVAL

A floating-point vector that indicates the distance (measured parametrically relative to the length of each contour path) between labels for each contour level. If the number of contour levels exceeds the number of provided intervals, the C_LABEL_INTERVAL values will be repeated cyclically. The default is 0.4.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## C_LABEL_NOGAPS

An integer vector that indicates whether gaps should be computed for the labels at the corresponding contour value. A zero value indicates that gaps will be computed for labels at that contour value; a non-zero value indicates that no gaps will be computed for labels at that contour value. If the number of contour levels exceeds the number of elements in this vector, the C_LABEL_NOGAPS values will be repeated cyclically. By default, gaps for the labels are computed for all levels (so that a contour line does not pass through the label).

| | | | |
|---|---|---|---|
| **Property Type** | Integer vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## C_LABEL_OBJECTS

An array of object references that provides examples of labels to be drawn for each contour level. The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a contour level. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a contour level.

By default, with C_LABEL_OBJECTS set equal to a null object, IDL computes text labels that are the string representations of the corresponding contour level values. Note that the objects specified via this property are used as descriptors only. The actual objects drawn as labels are generated by IDL, and may be accessed via the IDLgrContour::GetLabelInfo method. The contour labels will have the same color as the corresponding contour level (see C_COLOR) unless the C_USE_LABEL_COLOR property is specified. The orientation of the label will be automatically computed unless the C_USE_LABEL_ORIENTATION property is specified. The horizontal and vertical alignment of any text labels will default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS property is specified.

**Note**

The object(s) set via this property will not be destroyed automatically when the contour is destroyed.

| **Property Type** | Object reference array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## C_LABEL_SHOW

An integer vector that indicates whether labels are shown. For each contour value, if the corresponding value in the C_LABEL_SHOW vector is non-zero, the contour line for that contour value will be labeled. If the number of contour levels exceeds the

number of elements in this vector, the C_LABEL_SHOW values will be repeated cyclically. The default is 0 indicating that no contour levels will be labeled.

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## C_LINESTYLE

An integer array of linestyles that represent the linestyles to be applied at each contour level. The array may be either a vector of integers representing pre-defined linestyles, or an array of 2-element vectors representing a stippling pattern specification. If there are more contour levels than linestyles, the linestyles will be cyclically repeated. If this property is set to 0, all levels are drawn as solid lines (this is the default).

To use a pre-defined line style, set the C_LINESTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Linestyles | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## C_THICK

A floating-point array of line thicknesses that represent the thickness to be applied at each contour level, where each element is a value between 1.0 and 10.0. If there are more contour levels than line thicknesses, the thicknesses will be cyclically repeated.

If this property is set to 0, all contour levels are drawn with a line thickness of 1.0 points (this is the default).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Thicknesses | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## C_USE_LABEL_COLOR

An integer vector that indicates whether the COLOR property value for each of the label objects (for the corresponding contour level) is to be used to draw that label. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR properties of the label objects will be ignored, and the C_COLOR property for the contour object will be used instead.

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## C_USE_LABEL_ORIENTATION

An integer vector that indicates whether the orientation for each of the label objects (for the corresponding contour level) is to be used when drawing the label. For text, the orientation of the object corresponds to the BASELINE and UPDIR property values; for a symbol, this refers to the default (un-rotated) orientation of the symbol. If the number of contour levels exceeds the number of elements in this vector, the C_USE_LABEL_ORIENTATION values will be repeated cyclically. By default, this value is zero, indicating that orientation of the label object(s) will be set to automatically computed values (to correspond to the direction of the contour paths).

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## C_VALUE

A floating-point value or a floating-point vector for which contour values are to be drawn. If this property is set to 0, contour levels will be evenly sampled across the range of the DATA_VALUES, using the value of the N_LEVELS property to determine the number of samples. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Level values | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CLIP_PLANES

A 4-by-*N* floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A*x* + B*y* + C*z* + D = 0. Portions of this object that fall in the half space A*x* + B*y* + C*z* + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

The color to be used to draw the contours. The color may be specified as a color lookup table index or as an RGB vector. The default is [0,0,0]. This value will be ignored if the C_COLOR property is set to a vector.

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DATA_VALUES

A floating-point vector or two-dimensional array that specifies the values to be contoured. The property is the same as the *Values* argument described in the Arguments section above. IDL converts and stores this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE_DATA property is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

| **Property Type** | Floating-point vector or array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DAYS_OF_WEEK

A string vector of 7 values that indicates the names to be used for the days of the week when processing explicitly formatted dates (CDWA, CDwA, and CdwA format codes) with the LABEL_FORMAT property.

| **Property Type** | String vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

**Note**

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

**Note**

DEPTH_OFFSET has no effect unless the FILL property is set.

| **Property Type** | INTEGER | | |
|---|---|---|---|
| **Name String** | Depth offset | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.

- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DOUBLE_DATA

A Boolean value that indicates whether the object is to store data provided by either the *Values* argument or the DATA_VALUES property parameter in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any value data already stored in the object to the requested precision, if necessary.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DOUBLE_GEOM

A Boolean value that indicates whether the object is to store data provided by any of the GEOMX, GEOMY, or GEOMZ property parameters in double-precision or single-precision floating-point.

- 0 = Single-precision floating-point
- 1 = Double-precision floating-point

IDL converts any geometry data already stored in the object to the requested precision, if necessary.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DOWNHILL

A Boolean value that indicates whether downhill tick marks should be rendered as part of each contour level to indicate the downhill direction relative to the contour line.

- 0 = Do not render downhill tick marks.
- 1 = Render downhill tick marks

In a property sheet, this property appears as an enumerated list with the following options:

- Hide

- Show

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Downhill ticks | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## FILL

A Boolean value that indicates whether the contours should be filled. The default is to draw the contour levels as lines without filling. Filling contour may produce less than satisfactory results if your data contains NaNs, or if the contours are not closed.

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Fill contours | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## GEOM

A floating-point value that contains the geometry associated with the contour. IDL returns this data in single-precision floating-point by default or in double-precision floating-point if the DOUBLE_GEOM property is set in the IDLgrContour::Init method.

| **Property Type** | Floating-point | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## GEOMX

A floating-point vector or two-dimensional array that specifies the X coordinates of the geometry with which the contour values correspond. If X is a vector, it must match the number of elements in the *Values* argument or DATA_VALUES property value, or it must match the first of the two dimensions of the *Values* argument or DATA_VALUES property value (in which case, the X coordinates will be repeated for each row of data values). IDL converts and maintains this data as double-precision floating-point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single-

precision. IDL returns the data as double-precision if it was stored in double-precision.

| **Property Type** | Floating-point vector or array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GEOMY

A floating-point vector or two-dimensional array specifying the Y coordinates of the geometry with which the contour values correspond. If Y is a vector, it must match the number of elements in the *Values* argument or DATA_VALUES property value, or it must match the second of the two dimensions of the *Values* argument or DATA_VALUES property value (in which case, the Y coordinates will be repeated for each column of data values). IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

| **Property Type** | Floating-point vector or array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GEOMZ

A floating-point scalar, a vector, or a two-dimensional array specifying the Z coordinates of the geometry with which the contour values correspond.

- If GEOMZ is a scalar, and the PLANAR property is set, the resulting contour geometry will be projected onto the plane Z=GEOMZ. If GEOMZ is a scalar, and the PLANAR property is not set, any geometry associated with the contour will be freed.
- If GEOMZ is a vector of Z coordinates, the number of elements in the vector should be the same as the number of elements in DATA_VALUES.
- If GEOMZ is an array and the leading dimension is 3, then the data is treated as a list or array of 3-D vertices. The product of the array dimensions following the 3 should equal the number of DATA_VALUES.

- If GEOMZ is an array and the leading dimension is not 3, then the data is treated as a list or array of single Z coordinates. If the number of dimensions is 2, then the data is treated as a 2-D array of Z values. Otherwise, it is treated as a vector of Z values. In either case, the total number of elements in the array should be the same as the number of DATA_VALUES.
- If GEOMZ is not set, the geometry will be derived from the DATA_VALUES property (if it is set to a two-dimensional array). In this case, the connectivity is implied. The X and Y coordinates match the row and column indices of the array, and the Z coordinates match the data values.

IDL converts and maintains this data as double precision floating point if the parameter is of type DOUBLE or if the DOUBLE_GEOM property is non-zero. Otherwise, the data is stored in single precision. IDL returns the data as double precision if it was stored in double precision.

| **Property Type** | Floating-point scalar, vector, or array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LABEL_FONT

An object reference to an IDLgrFont object that describes the default font to be used for contour labels. This font will be used for all text labels automatically generated by

IDL (i.e., if C_LABEL_SHOW is set but the corresponding C_LABEL_OBJECTS text object is not provided), or for any text label objects provided via C_LABEL_OBJECTS that do not already have the font property set. The default value for this property is a NULL object reference, indicating that 12 pt. Helvetica will be used.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LABEL_FORMAT

A string that represents a format string or the name of a function to be used to format the contour labels. If the string begins with an open parenthesis, it is treated as a standard format string. (Refer to the Format Codes in the IDL Reference Guide.) If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate contour level labels.

The callback function is called with three parameters: Axis, Index, and Value, where:

- Axis is simply the value 2 to indicate that values along the Z axis are being formatted. (This allows a single callback routine to be used for both axis labeling and contour labeling.)
- Index is the contour level index (indices start at 0).
- Value is the data value of the current contour level.

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LABEL_FRMTDATA

A user-defined value of any type passed via the DATA keyword to the user-supplied formatting function specified via the LABEL_FORMAT property, if any. By default, this value is 0, indicating that the DATA keyword will not be set (and furthermore, need not be supported by the user-supplied function).

**Note**

LABEL_FRMTDATA will not be included in the structure returned via the ALL property to the IDLgrContour::GetProperty method.

| **Property Type** | Scalar of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## LABEL_UNITS

A string that indicates the units to be used for default contour level labeling.

Valid unit strings include:

- "Numeric"
- "Years"
- "Months"
- "Days"
- "Hours"
- "Minutes"
- "Seconds"
- "Time" - Use this value to indicate that the contour levels correspond to time values; IDL will determine the appropriate label format based upon the range of values covered by the contour Z data.
- "" - The empty string is equivalent to the "Numeric" unit. This is the default.

If any of the time units are utilized, then the contour values are interpreted as Julian date/time values.

**Note**

The singular form of each of the time unit strings is also acceptable (for example, LEVEL_UNITS='Day' is equivalent to LEVEL_UNITS='Days').

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## MAX_VALUE

A floating point value that indicates the maximum value to be plotted. Data values greater than this value are treated as missing data. The default is the maximum value of the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Maximum value | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## MONTHS

A string vector of 12 values indicating the names to be used for the months when processing explicitly formatted dates (CMOA, CMoA, and CmoA format codes) with the C_LABEL_FORMAT keyword.

| **Property Type** | String vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## MIN_VALUE

A floating-point value that indicates the minimum value to be plotted. Data values less than this value are treated as missing data. The default is the minimum value of

the input Z data. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Minimum value | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## N_LEVELS

An integer value that indicates the number of contour levels to generate. This property is ignored if the C_VALUE property is set to a vector, in which case, the number of levels is derived from the number of elements in that vector. Set this property to zero to indicate that IDL should compute a default number of levels based on the range of data values. This is the default.

| **Property Type** | INTEGER | | |
|---|---|---|---|
| **Name String** | Number of levels | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this contour.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## PLANAR

A Boolean value that indicates whether the contoured data is to be projected onto a plane. This property is ignored if GEOMZ is not a scalar. The default is non-planar (i.e., to display the contoured data at the Z locations provided by the GEOMZ property.

In a property sheet, this property appears as an enumerated list with the following options:

- Planar (the default)
- Three-D

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Projection | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## POLYGONS

An integer array of polygon descriptions that represents the connectivity information for the data to be contoured (as specified in the *Values* argument or the DATA_VALUES property). A polygon description is an integer or long word array of the form: [*n*, i0, i1, ..., i*n*-1], where *n* is the number of vertices that define the polygon, and i0..i*n*-1 are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count, *n*, to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this property is not specified, a single polygon will be generated.

**Note**

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be

shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

| | | | |
|---|---|---|---|
| **Property Type** | Integer array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. This value is ignored when the contour is drawn to a graphics destination that uses the RGB color model.

| | | | |
|---|---|---|---|
| **Property Type** | Integer array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHADING

An integer that indicates the type of shading to use:

- 0 = Flat (default): The color has a constant intensity for each face of the contour, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat (the default)
- Gouraud

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Shading | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TICKINTERVAL

A floating-point value that indicates the distance between downhill tickmarks, in data units. If TICKINTERVAL is not set, or if you explicitly set it to zero, IDL will compute the distance based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point.

| | | | |
|---|---|---|---|
| **Property Type** | FLOAT | | |
| **Name String** | Downhill tick interval | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TICKLEN

A floating-point value that indicates the length of the downhill tickmarks, in data units. If TICKLEN is not set, or if you explicitly set it to zero, IDL will compute the length based on the geometry of the contour. IDL converts, maintains, and returns this data as double-precision floating-point

| | | | |
|---|---|---|---|
| **Property Type** | FLOAT | | |
| **Name String** | Downhill tick length | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## USE_TEXT_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the C_LABEL_OBJECTS property), the ALIGNMENT and

VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw the corresponding labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the label IDLgrText object(s) will be set to default values (0.5 for each, indicating centered labels).

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] specifying the range of the *X* data coordinates covered by the contour.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the contour.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that converts Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of the *Z* data coordinates covered by the contour.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrContour::AdjustLabelOffsets

The IDLgrContour::AdjustLabelOffsets procedure method adjusts the offsets at which contour labels are positioned.

## Syntax

*Obj* -> [IDLgrContour::]AdjustLabelOffsets, *LevelIndex*, *LabelOffsets*

## Arguments

### LevelIndex

The index of the contour level for which the label offsets are being adjusted. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS property in the IDLgrContour::Init method).

### LabelOffsets

A scalar or vector of floating point offsets, [t0, t1, …], that indicate the parametric offsets along the length of each contour line at which each label is to be positioned. The number of elements in this vector must exactly match the number of elements returned in the LABEL_OFFSETS vector retrieved via the IDLgrContour::GetLabelInfo method for the same level.

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrContour::Cleanup

The IDLgrContour::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrContour::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrContour::GetCTM

The IDLgrContour::GetCTM method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrContour::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref*] )

## Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrContour::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.1

# IDLgrContour::GetLabelInfo

The IDLgrContour::GetLabelInfo procedure method retrieves information about the labels for a contour. The returned information is only valid until the next time the C_LABEL_INTERVAL or C_LABEL_OBJECTS property is modified using the IDLgrContour::SetProperty method, or the offsets are adjusted using the IDLgrContour::AdjustLabelOffsets method.

# Syntax

*Obj* -> [IDLgrContour::]GetLabelInfo, *Destination*, *LevelIndex*
[, LABEL_OFFSETS=*variable*] [, LABEL_POLYS=*variable*]
[, LABEL_OBJECTS=*variable*]

# Arguments

## Destination

A reference to a destination object (such as an IDLgrWindow or IDLgrBuffer object). The contour label information will be computed so that the requested font size is satisfied for this destination device.

## LevelIndex

The index of the contour level for which the label information is being requested. This value must be greater than or equal to zero and less than the number of levels (refer to the N_LEVELS keyword in the IDLgrContour::Init method).

# Keywords

## LABEL_OFFSETS

Set this keyword to a named variable that upon return will contain a vector of floating point offsets, [t0, t1, …], that indicate the parametric offsets along the length of each contour line at which the contour labels are positioned.

## LABEL_POLYLINES

Set this keyword to a named variable that upon return will contain a vector of contour polyline indices, [$P_0$, $P_1$, …], that indicate which contour lines are labeled. $P_i$ corresponds to the ith contour line.

Note that if a given contour line has more than one label along its perimeter, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector.

### LABEL_OBJECTS

Set this keyword to a named variable that upon return will contain a vector of objects that represent the labels for each contour label.

## Version History

Introduced: 5.1

# IDLgrContour::GetProperty

The IDLgrContour::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

## Syntax

*Obj* -> [IDLgrContour::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrContour Properties” on page 3241 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.1

# IDLgrContour::Init

The IDLgrContour::Init function method initializes the contour object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrContour' [, *Values*] [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLgrContour::]Init([*Values*] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Values

A vector or two-dimensional array of values to be contoured. If no values are provided, the values will be derived from the GEOMZ keyword value (if set and the PLANAR keyword is not set). In this case, the values to be contoured will match the Z coordinates of the provided geometry. IDL converts and maintains this data as double-precision floating-point if the argument is of type DOUBLE or if the DOUBLE_DATA keyword is set. Otherwise, the data is stored in single-precision. IDL returns the data as double-precision if it was stored in double-precision.

## Keywords

Any property listed under “IDLgrContour Properties” on page 3241 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.1

AM_PM, C_LABEL_INTERVAL, CLIP_PLANES, C_LABEL_OBJECTS, C_LABEL_NOGAPS, C_LABEL_SHOW, C_USE_LABEL_COLOR, C_USE_LABEL_ORIENTATION, DAYS_OF_WEEK, LABEL_FONT, LABEL_FORMAT, LABEL_FRMATDATA, LABEL_UNITS, MONTHS, USE_TEXT_ALIGNMENTS keywords: 5.6

# IDLgrContour::SetProperty

The IDLgrContour::SetProperty procedure method sets the value of a property or group of properties for the contour.

## Syntax

*Obj* -> [IDLgrContour::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrContour Properties” on page 3241 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.1

# IDLgrFont

A font object represents a typeface, style, weight, and point size that may be associated with text objects.

## Superclasses

IDLitComponent

## Creation

See "IDLgrFont::Init" on page 3281.

## Properties

Objects of this class have the following properties. See "IDLgrFont Properties" on page 3277 for details on individual properties.

- ALL
- SIZE
- SUBSTITUTE
- THICK

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrFont::Cleanup
- IDLgrFont::GetProperty
- IDLgrFont::Init
- IDLgrFont::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrFont Properties

IDLgrFont objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrFont::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrFont::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrFont::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL..

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## SIZE

A floating-point value representing the point size of the font. The default is 12.0 points.

| **Property Type** | Floating-point | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SUBSTITUTE

A string that indicates the font to use as a substitute if the specified *Fontname* is not available on the graphics destination. Valid values are only those fonts that are

available on all destination objects (the fonts included with IDL). These are: 'Helvetica' (the default), 'Courier', 'Times', 'Symbol', or 'Hershey'.

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## THICK

A floating-point value between 1.0 and 10.0, indicating the line thickness (measured in points) to use for the Hershey vector fonts. The default is 1.0 points.

| **Property Type** | Floating-point | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLgrFont::Cleanup

The IDLgrFont::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrFont::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrFont::GetProperty

The IDLgrFont::GetProperty procedure method retrieves the value of a property or group of properties for the font.

## Syntax

*Obj* -> [IDLgrFont:]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrFont Properties” on page 3277 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrFont::Init

The IDLgrFont::Init function method initializes the font object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

# Syntax

*Obj* = OBJ_NEW('IDLgrFont' [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLgrFont::]Init([*Fontname*] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

# Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

# Arguments

## Fontname

A string representing the name of the font to be used. This string should take the form 'fontname*modifier1*modifier2*...*modifierN'. All destination objects support the following fontnames: Helvetica, Courier, Times, Symbol, and Monospace Symbol. (These fonts are included with IDL; you may have other fonts installed on your system as well.) Valid modifiers for each of these fonts (except Symbol and Monospace Symbol) are:

- *Font weight:* Bold
- *Font angle:* Italic

For example, 'Helvetica*Bold*Italic'.

To select a Hershey font, use a fontname of the form: 'Hershey*fontnum'. See Appendix H, “Fonts” for further information and a list of fonts supported by IDL.

**Note**

Beginning with IDL version 5.1, only TrueType and Hershey fonts are supported in the Object Graphics system.

## Keywords

Any property listed under “IDLgrFont Properties” on page 3277 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

# IDLgrFont::SetProperty

The IDLgrFont::SetProperty procedure method sets the value of a property or group of properties for the font.

## Syntax

*Obj* -> [IDLgrFont:]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrFont Properties” on page 3277 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrImage

An image object represents a mapping from a two-dimensional array of data values to a two dimensional array of pixel colors, resulting in a flat 2-D-scaled version of the image, drawn at Z = 0.

The image object is drawn at Z =0 and is positioned and sized with respect to two points:

```
p1 = [LOCATION(0), LOCATION(1), 0]
p2 = [LOCATION(0) + DIMENSION(0), LOCATION(1) + DIMENSION(1), 0].
```

where LOCATION and DIMENSION are properties of the image object. These points are transformed in three dimensions, resulting in screen space points designated as p1' and p2'. The image data is drawn on the display as a 2-D image within the 2-D rectangle defined by (p1'[0], p1'[1] - p2'[0], p2'[1]). The 2-D image data is scaled in 2-D (not rotated) to fit into this projected rectangle and then drawn with Z buffering disabled

**Note**

Image objects do not take into account the Z locations of other objects that may be included in the view object. This means that objects that are drawn to the destination object (window or printer) *after the image is drawn* will appear to be in front of the image, even if they are located at a negative Z value (behind the image object). Objects are drawn to a destination device in the order that they are added (via the Add method) to the model, view, or scene that contains them. To rotate or position image objects in three-dimensional space, use the IDLgrPolygon object with texture mapping enabled.

An IDLgrImage object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

IDLitComponent

## Creation

See “IDLgrImage::Init” on page 3304.

## Properties

Objects of this class have the following properties. See “IDLgrImage Properties” on page 3287 for details on individual properties.

- ALL
- BLEND_FUNCTION
- CHANNEL
- CLIP_PLANES
- DATA
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- DIMENSIONS
- GREYSCALE
- HIDE
- INTERLEAVE
- INTERPOLATE
- LOCATION
- NO_COPY
- ORDER
- PALETTE
- PARENT
- REGISTER_PROPERTIES
- RESET_DATA
- SHARE_DATA
- SUB_RECT
- XCOORD_CONV
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrImage::Cleanup
- IDLgrImage::GetCTM
- IDLgrImage::GetProperty
- IDLgrImage::Init
- IDLgrImage::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrImage Properties

IDLgrImage objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrImage::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrImage::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrImage::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## BLEND_FUNCTION

A two-element integer vector that controls how the alpha channel values will be interpreted. Set this property equal to a two-element vector [*src*, *dst*] specifying one of the functions listed below for each of the source and destination objects. These are only valid for RGB model destinations. If an alpha channel is not specified in an image, the image’s alpha blend factor is assumed to be 1.0. The values of the blending function ($V_{src}$ and $V_{dst}$) are used in the following equation

$$C_d' = (V_{src} \cdot C_i) + (V_{dst} \cdot C_d)$$

where $C_d$ is the initial color of a pixel on the destination device (the background color), $C_i$ is the color of the pixel in the image, and $C_d'$ is the resulting color of the pixel.

Setting *src* and *dst* in the BLEND_FUNCTION vector to the following values determine how each term in the equation is calculated:

| src or dst | $V_{src}$ or $V_{dst}$ | What the function does |
|---|---|---|
| 0 | n/a | Alpha blending is disabled, which is the default setting. $C_d' = C_i$ |
| 1 | 0 | The value of $V_{src}$ or $V_{dst}$ in the equation is zero, thus the value of the term is zero. |
| 2 | 1 | The value of $V_{src}$ or $V_{dst}$ in the equation is one, thus the value of the term is the same as the color value. |
| 3 | $Image_a$ | The value of $V_{src}$ or $V_{dst}$ in the equation is the blend factor of the image's alpha channel. |
| 4 | $1\text{-}Image_a$ | The value of $V_{src}$ or $V_{dst}$ in the equation is one minus the blend factor of the image's alpha channel. |

*Table 8-4: Values for src and dst in BLEND_FUNCTION*

For example, setting BLEND_FUNCTION = [3, 4] creates an image in which you can see through the foreground image to the background to the extent defined by the alpha channel values of the foreground image.

Since the alpha blending operation is dependent on the values of pixels already drawn to the destination for some blending functions, the final result may depend more on the order of drawing the images, and not necessarily on their relative location along the Z axis. IDL draws images in the order that they are stored in the IDLgrModel object that contains them.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Blend function | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CHANNEL

A hexadecimal bitmask that defines which color channel(s) to draw. Each bit that is a 1 is drawn; each bit that is a 0 is not drawn. For example, 'ff0000'X represents a Blue channel write. The default is to draw all channels, and is represented by the hexadecimal value 'ffffff'X.

**Note**

This property is ignored for CI destination objects.

This property is registered, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | INTEGER | | |
| **Name String** | Color channel | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CLIP_PLANES

A 4-by-*N* floating-point array of dimensions [4,N] specifying the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A*x* + B*y* + C*z* + D = 0. Portions of this object that fall in the half space A*x* + B*y* + C*z* + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DATA

A *n* x *m*, *2 x n x m*, *3 x n* x *m*, or *4 x n* x *m* array (any type) of image data for the object. The *n* and *m* values may be in any position as specified by the INTERLEAVE property. This property is equivalent to the optional argument, *ImageData*.

| | | | |
|---|---|---|---|
| **Property Type** | Array of any type | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the dimensions of the rectangle in which the image is to be drawn on the device. The image will be resampled as necessary to fit within this rectangle. The default is derived from the dimensions of the given image data and is measured in pixels. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Draw dimensions | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## GREYSCALE

A Boolean value that determines whether the image is drawn through a palette.

0 = Use palette (the default).

1 = Do not use a palette.

If this property is not set, for an RGB color model destination, if a palette is present in the image object, it is used. If there is no current destination palette, a greyscale palette is used. For a Color Index color model destination, the current destination palette is used.

**Note**

Only single band images (i.e. *1 x n x m*) are affected by this property. By default, GREYSCALE is disabled.

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Grayscale | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## INTERLEAVE

An integer value that indicates the dimension over which color is interleaved for images with more than one channel:

- 0 = Pixel interleaved: Images with dimensions (3, *m*, *n*)
- 1 = Scan line interleaved (row interleaved): Images with dimensions (*m*, 3, *n*)
- 2 = Planar interleaved: Images with dimensions (*m*, *n*, 3).

**Note**

If an alpha channel is present, the 3s should be replaced by 4s. In a greyscale image with an alpha channel, the 3s should be replaced by 2s.

In a property sheet, this property appears as an enumerated list with the following options:

- Pixel
- Scanline
- Planar.

This property is registered, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Interleaving | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## INTERPOLATE

An integer value to determine whether to display the IDLgrImage object using bilinear interpolation. The default is to use nearest neighbor interpolation.

- 0 = Nearest neighbor interpolation (the default)
- 1 = Bilinear interpolation

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Bilinear

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Interpolation | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LOCATION

A two- or three-element floating-point vector [*x*, *y*] or [*x*, *y*, *z*] specifying the position of the lower lefthand corner of the image, measured in data units. If the vector is of the form [*x*, *y*], then the *z* value is set equal to zero. The default is [0, 0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Location | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## NO_COPY

A Boolean value that determines whether to relocate the image data from the input variable to the image object, leaving the input variable *ImageData* undefined. Only the *ImageData* argument is affected. If this property is omitted, the input image data will be duplicated and a copy will be stored in the object.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ORDER

A Boolean value that determines whether to force the rows of the image data to be drawn from top to bottom. By default, image data is drawn from the bottom row up to the top row.

In a property sheet, this property appears as and enumerated list with the following options:

- Bottom-to-top
- Top-to-bottom

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Row order | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

**Note**

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RESET_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects.

- 0 = Overwrite data that is shared by other objects (the default).
- 1 = Treat DATA as a new data set unique to this object.

There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHARE_DATA

An object reference to an object with which data is to be shared by this image. An image may only share data with another image. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SUB_RECT

A four-element floating-point vector, [*x, y, xdim, ydim*], specifying the position of the lower left-hand corner and the dimensions of the sub-rectangle to display.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Sub-rectangle | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## XCOORD_CONV

A floating-point vector, [$s_0$, $s_1$], of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

Two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrImage::Cleanup

The IDLgrImage::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrImage::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrImage::GetCTM

The IDLgrImage::GetCTM function method returns the 4 x 4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrImage::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*] )

## Return Value

Returns the graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the image object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrImage::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrImage::GetProperty

The IDLgrImage::GetProperty procedure method retrieves the value of the property or group of properties for the image.

## Syntax

*Obj* -> [IDLgrImage::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrImage Properties” on page 3287 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrImage::Init

The IDLgrImage::Init function method initializes the image object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

# Syntax

*Obj* = OBJ_NEW('IDLgrImage' [, *ImageData*] [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLgrImage::]Init([*ImageData*] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

# Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

# Arguments

## ImageData

An array of data values to be displayed as an image. If this argument is not already of byte type, it is converted to byte type when the image object is created. Since IDL maintains the image data using the byte type, the input data values should range from 0 through 255. Image objects can have a single channel (one value per pixel—greyscale or color indexed), two channels (greyscale and alpha), three channels (red, green, and blue), or four channels (red, green, blue, and alpha). The alpha channel, if present, determines the transparency of the pixel. The BLEND_FUNCTION property controls the interpretation of the alpha channel values. With channels, the data value of 0 specifies minimum intensity and the data value of 255 specifies maximum intensity. The alpha channel values are also specified in the image data in the range 0

through 255, with an image data value of 0 corresponding to an alpha blend factor of 0 and an image data value of 255 corresponding to an alpha blend factor of 1.0. *ImageData* can be any of the following, where *n* is the width of the image, and *m* is the height:

- An *n* x *m* array of color lookup table indices.
- An *n* x *m* greyscale image, or a 2 x *n* x *m*, *n* x 2 x *m*, or *n* x *m* x 2 greyscale image with an alpha channel. (The alpha channel is ignored if the destination device uses indexed color mode.)
- A 3 x *n* x *m*, *n* x 3 x *m*, or *n* x *m* x 3 RGB image, or a 4 x *n* x *m*, *n* x 4 x *m*, or *n* x *m* x 4 RGB image with an alpha channel.

If the array has more than one channel, the interleave is specified by the INTERLEAVE property.

## Keywords

Any property listed under "IDLgrImage Properties" on page 3287 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

# IDLgrImage::SetProperty

The IDLgrImage::SetProperty procedure method sets the value of the property or group of properties for the image.

## Syntax

*Obj* -> [IDLgrImage::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrImage Properties” on page 3287 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrLegend

The IDLgrLegend object provides a simple interface for displaying a legend. The legend itself consists of a (filled and/or framed) box around one or more legend items (arranged in a single column) and an optional title string. Each legend item consists of a glyph patch positioned to the left of a text string. The glyph patch is drawn in a square which is a fraction of the legend label font height. The glyph itself can be in one of two types (see the TYPE keyword). In line type, the glyph is a line segment with linestyle, thickness and color attributes and an optional symbol object drawn over it. In fill type, the glyph is a square patch drawn with color and optional pattern object attributes.

An IDLgrLegend object is a *composite object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

This object class is implemented in the IDL language. Its source code can be found in the file `idlgrlegend__define.pro` in the `lib` subdirectory of the IDL distribution.

## Superclasses

IDLgrModel

IDLitComponent

## Creation

See “IDLgrLegend::Init” on page 3324.

## Properties

Objects of this class have the following properties. See “IDLgrLegend Properties” on page 3310 for details on individual properties.

- ALL
- BORDER_GAP
- COLUMNS
- FILL_COLOR
- FONT

- GAP
- GLYPH_WIDTH
- HIDE
- ITEM_COLOR
- ITEM_LINESTYLE
- ITEM_NAME
- ITEM_OBJECT
- ITEM_THICK
- ITEM_TYPE
- OUTLINE_COLOR
- OUTLINE_THICK
- PARENT
- RECOMPUTE
- SHOW_FILL
- SHOW_OUTLINE
- TEXT_COLOR
- TITLE
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrLegend::Cleanup
- IDLgrLegend::ComputeDimensions

- IDLgrLegend::GetProperty
- IDLgrLegend::Init
- IDLgrLegend::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.1

# IDLgrLegend Properties

IDLgrLegend objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrLegend::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrLegend::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrLegend::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## BORDER_GAP

A floating-point value to indicate the amount of blank space to be placed around the outside of the glyphs and text items. The units for this property are fractions of the legend label font height. The default is 0.1 (10% of the label font height).

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLUMNS

An integer value to indicate the number of columns the legend items should be displayed in. The default is one column.

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## FILL_COLOR

The color to be used to fill the legend background box. The color may be specified as a color lookup table index or as an RGB vector. The default is [255,255,255].

| | | | |
|---|---|---|---|
| **Property Type** | COLOR | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## FONT

An object reference to an instance of an IDLgrFont object class that describes the font to use to draw the legend labels. The default is 12 point Helvetica.

**Note**

If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a font object that will be destroyed when this legend object is destroyed, leaving a dangling object reference.

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GAP

A floating-point value that indicates the amount of blank space to be placed vertically between each legend item. The units for this property are fractions of the legend label

font height. The default is 0.1 (10% of the label font height). The same gap is placed horizontally between the legend glyph and the legend text string.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GLYPH_WIDTH

A floating-point value to indicate the width of the glyphs, measured as a fraction of the font height. The default is 0.8 (80% of the font height).

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ITEM_COLOR

An array of colors defining the color of each item. The array defines *M* different colors, and should be either of the form [3,*M*] or [*M*]. In the first case, the three values are used as an RGB triplet, in the second case, the single value is used as a color index value. The default color is [0,0,0].

| | | | |
|---|---|---|---|
| **Property Type** | Color array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ITEM_LINESTYLE

An integer array of integers defining the style of the line to be drawn if the TYPE property is set to zero. The array can be of the form [*M*] or [2,*M*]. The first form selects the linestyle for each legend item from the predefined defaults:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot
- 5 = long dash
- 6 = no line drawn

The second form specifies the stippling pattern explicitly for each legend item (see the LINESTYLE property to IDLgrPolyline::Init for details).

| **Property Type** | Integer array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ITEM_NAME

An string array representing the names of items in the legend. Specifying this property is the same as providing the *aName* argument for the IDLgrLegend::Init method.

| **Property Type** | String array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ITEM_OBJECT

An array of object references of type IDLgrSymbol or IDLgrPattern that represents the shapes of the items in the legend. A symbol object is drawn only if the TYPE property is set to zero. A pattern object is used when drawing the color patch if the TYPE property is set to one. The default object is the NULL object.

**Note**

If one or more IDlgrSymbol object references are provided, the SIZE property of those objects may be modified by this legend to suit its layout needs.

| | | | |
|---|---|---|---|
| **Property Type** | Object reference array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ITEM_THICK

A floating-point array of floating-point values that define the thickness of each item line, in points, where each element is a value between 1.0 and 10.0. This property is only used if the TYPE property is set to zero. The default is 1.0 points.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ITEM_TYPE

An integer array that defines the type of glyph to be displayed for each item:

- 0 = line type (the default)
- 1 = filled box type

| | | | |
|---|---|---|---|
| **Property Type** | Integer array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## OUTLINE_COLOR

The color to be used to draw the legend outline box. The color may be specified as a color lookup table index or as an RGB vector. The default is [0,0,0].

| | | | |
|---|---|---|---|
| **Property Type** | Color | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## OUTLINE_THICK

A floating-point value between 1.0 and 10.0 that defines the thickness of the outline frame, in points. The default is 1.0 points.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PARENT

An object reference to the object that contains this legend.

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## RECOMPUTE

A Boolean value that determines whether to recompute the legend dimensions when the legend is redrawn.

- 0 = Prevent IDL from recomputing legend dimensions (the default).
- 1 = Recompute the legend dimensions when the legend is redrawn.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** No | **Registered:** No |

## SHOW_FILL

A Boolean value that indicates whether the background should be filled with a color:

- 0 = Do not fill background (the default)
- 1 = Fill background

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHOW_OUTLINE

A Boolean value indicating whether the outline box should be displayed:

- 0 = Do not display outline (the default)
- 1 = Display outline

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TEXT_COLOR

The color to be used to draw the legend item text. The color may be specified as a color lookup table index or as an RGB vector. The default is [0,0,0].

| **Property Type** | Color | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TITLE

An object reference to an instance of the IDLgrText object class to specify the title for the legend. The default is the null object, specifying that no title is drawn. The

title will be centered at the top of the legend, even if the text object itself has an associated location.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of the *X* data coordinates covered by the legend.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of the *Y* data coordinates covered by the legend.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of the *Z* data coordinates covered by the legend.

**Note**

Until the legend is drawn to the destination object, the [XYZ]RANGE properties will be zero. Use the ComputeDimensions method on the legend object to get the data dimensions of the legend prior to a draw operation.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrLegend::Cleanup

The IDLgrLegend::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrLegend::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrLegend::ComputeDimensions

The IDLgrLegend::ComputeDimensions function method retrieves the dimensions of a legend object for the given destination object. The result is a three-element double-precision floating-point vector [*xDim, yDim, zDim*] representing the dimensions of the legend object measured in data units.

## Syntax

*Result* = *Obj* ->[IDLgrLegend::]ComputeDimensions( *DestinationObject* [, PATH=*objref(s)*] )

## Return Value

Returns the dimensions of a legend object for the given destination object.

## Arguments

### DestinationObject

The object reference to a destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) for which the dimensions of the legend are being requested.

## Keywords

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLegend::ComputeDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## Version History

Introduced: 5.1

# IDLgrLegend::GetProperty

The IDLgrLegend::GetProperty procedure method retrieves the value of a property or group of properties for the legend.

## Syntax

*Obj* -> [IDLgrLegend::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under "IDLgrLegend Properties" on page 3310 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

## Version History

Introduced: 5.1

# IDLgrLegend::Init

The IDLgrLegend::Init function method initializes the legend object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrLegend' [, *aItemNames*] [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrLegend::]Init([*aItemNames*] [, *PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### aItemNames

An array of strings to be used as the displayed item label. The length of this array is used to determine the number of items to be displayed. Each item is defined by taking one element from the ITEM_NAME, ITEM_TYPE, ITEM_LINESTYLE, ITEM_THICK, ITEM_COLOR, and ITEM_OBJECT vectors. If the number of items (as defined by the ITEM_NAME array) exceeds any of the attribute vectors, the attribute defaults will be used for any additional items.

## Keywords

Any property listed under “IDLgrLegend Properties” on page 3310 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.1

# IDLgrLegend::SetProperty

The IDLgrLegend::SetProperty procedure method sets the value of a property or group of properties for the legend.

## Syntax

*Obj*->[IDLgrLegend::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrLegend Properties” on page 3310 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.1

# IDLgrLight

A light object represents a source of illumination for three-dimensional graphic objects. Lights may be either ambient, positional, directional, or spotlights. A maximum of 8 lights per view are allowed. Lights are not required for objects displayed in two dimensions.

An IDLgrLight object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

IDLitComponent

## Creation

See "IDLgrLight::Init" on page 3340.

## Properties

Objects of this class have the following properties. See "IDLgrLight Properties" on page 3329 for details on individual properties.

- ALL
- ATTENUATION
- COLOR
- CONEANGLE
- DIRECTION
- FOCUS
- HIDE
- INTENSITY
- LOCATION
- PALETTE
- PARENT
- REGISTER_PROPERTIES

- TYPE
- XCOORD_CONV
- YCOORD_CONV
- ZCOORD_CONV

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrLight::Cleanup
- IDLgrLight::GetCTM
- IDLgrLight::GetProperty
- IDLgrLight::Init
- IDLgrLight::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrLight Properties

IDLgrLight objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrLight::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrLight::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrLight::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ATTENUATION

A 3-element floating-point vector of the form [constant, linear, quadratic] that describes the factor by which light intensity is to fall with respect to distance from the light source. ATTENTUATION applies only to Positional and Spot lights, as specified by the TYPE property. The overall attenuation factor is computed as follows:

```
attenuation = 1/(constant + linear*distance +
quadratic*distance^2)
```

By default, the values are [1, 0, 0].

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Attenuation | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## COLOR

A three-element byte vector specifying the RGB color of the light. The default is [255, 255, 255], which is a white light. The color of a light is ignored when graphics are sent to graphics destinations using the Indexed color model, in which case light intensities are scaled into the range of colors available on the graphics destination.

In a property sheet, this property appears as a color property.

| | | | |
|---|---|---|---|
| **Property Type** | COLOR | | |
| **Name String** | Color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CONEANGLE

A floating-point value that specifies the angle (measured in degrees) of coverage for a spotlight. The default is 60.

| | | | |
|---|---|---|---|
| **Property Type** | FLOAT | | |
| **Name String** | Spotlight cone angle | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DIRECTION

A three-element floating-point vector representing the direction in which a spotlight is to be pointed. The default is [0,0,-1].

**Note**

For directional lights, the light's parallel rays follow a vector beginning at the position specified by LOCATION and ending at [0, 0, 0].

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Spotlight direction | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## FOCUS

A floating-point value that describes the attenuation of intensity for spotlights as the distance from the center of the cone of coverage increases. This factor is used as an exponent to the cosine of the angle between the direction of the spotlight and the direction from the light to the vertex being lighted. The default is 0.0.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Spotlight attenuation | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value that indicates whether this light should be enabled:

- 0 = Enable light (the default)
- 1 = Disable light

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

**Note**

If no lights are present in the view (or if all lights in the view are hidden), an ambient light will be provided by default..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## INTENSITY

A floating-point value between 0.0 (darkest) and 1.0 (brightest) that indicates the intensity of the light. The default is 1.0.

| | | | |
|---|---|---|---|
| **Property Type** | FLOAT | | |
| **Name String** | Intensity | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LOCATION

A floating-point vector of the form [*x*, *y*, *z*] describing the position of the light. By default, the position is [0, 0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Location | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values of the color lookup table to be associated with the image if it is an indexed color image. This property is ignored if the image is a greyscale or RGB image.

**Note**

This table is only used when the destination is an RGB model device. The Indexed color model writes the indices directly to the device. In order to ensure that these colors are used when the image is displayed, this palette must be copied to the graphics destination's palette for any graphics destination that uses the Indexed color model.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## TYPE

An integer that indicates the type of light. Valid values are:

- 0 = Ambient light. An ambient light is a universal light source, which has no direction or position. An ambient light illuminates every surface in the scene equally, which means that no edges are made visible by contrast. Ambient lights control the overall brightness and color of the entire scene. If no value is specified for the TYPE property, an ambient light is created.
- 1 = Positional light. A positional light supplies divergent light rays, and will make the edges of surfaces visible by contrast if properly positioned. A positional light source can be located anywhere in the scene.

- 2 = Directional light. A directional light supplies parallel light rays. The effect is that of a positional light source located at an infinite distance from scene.
- 3 = Spot light. A spot light illuminates only a specific area defined by the light's position, direction, and the cone angle, or angle which the spotlight covers.

In a property sheet, this property appears as an enumerated list with the following options:

- Ambient
- Positional
- Directional
- Spotlight

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Type | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Double-precision floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Double-precision floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors that convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Double-precision floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLgrLight::Cleanup

The IDLgrLight::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrLight::]Cleanup (*Only in subclass' Cleanup method.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrLight::GetCTM

The IDLgrLight::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrLight::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*] )

## Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the light object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrLight::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrLight::GetProperty

The IDLgrLight::GetProperty procedure method retrieves the value of a property or group of properties for the light.

## Syntax

*Obj* -> [IDLgrLight::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrLight Properties” on page 3329 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrLight::Init

The IDLgrLight::Init function method initializes the light object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrLight' [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLgrLight::]Init([*PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrLight Properties" on page 3329 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

# IDLgrLight::SetProperty

The IDLgrLight::SetProperty procedure method sets the value of a property or group of properties for the light.

## Syntax

*Obj* -> [IDLgrLight::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrLight Properties” on page 3329 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrModel

A model object represents a graphical item or group of items that can be transformed (rotated, scaled, and/or translated). It serves as a container of other IDLgrModel objects or atomic graphic objects. IDLgrModel applies a transform to the current view tree.

## Superclasses

IDL_Container

## Creation

See "IDLgrModel::Init" on page 3359.

## Properties

Objects of this class have the following properties. See "IDLgrModel Properties" on page 3345 for details on individual properties.

- ALL
- CLIP_PLANES
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- HIDE
- LIGHTING
- PARENT
- REGISTER_PROPERTIES
- SELECT_TARGET
- TRANSFORM

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has this following methods:

- IDLgrModel::Add
- IDLgrModel::Cleanup
- IDLgrModel::Draw
- IDLgrModel::GetByName
- IDLgrModel::GetCTM
- IDLgrModel::GetProperty
- IDLgrModel::Init
- IDLgrModel::Reset
- IDLgrModel::Rotate
- IDLgrModel::Scale
- IDLgrModel::SetProperty
- IDLgrModel::Translate

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrModel Properties

IDLgrModel objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrModel::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrModel::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrModel::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with this object.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## CLIP_PLANES

An 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B ,C, D], where A$x$ + B$y$ + C$z$ + D = 0.

Portions of this object that fall in the half space A$x$ + B$y$ + C$z$ + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Note - Clipping planes are applied in the data space of the objects this model contains (prior to the application of this model's transform).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Clipping planes | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always

sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.

- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw model and children (the default)
- 1 = Do not draw model or children

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic.

**Note**

HIDE only controls the display attributes of IDLgrModel children since the IDLgrModel object itself lacks geometry..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LIGHTING

An integer value that indicates whether lighting is to be enabled or disabled for all atomic graphic objects that have this model as a parent. IDLgrModel objects that have this model as a parent will not be effected, as they have their own value for this

property. If this value is set to 0, any lights added as children of this model will be used to illuminate any other models in the view hierarchy that have lighting enabled.

- 0 = Disable lighting
- 1 = Enable single-sided lighting
- 2 = Enable double-sided lighting (the default)

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Lighting | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## SELECT_TARGET

A Boolean value that tags the model object as the target object to be returned when any object contained by the model is selected via the IDLgrWindow::Select method.

- 0 = Do not tag the model object as the target object (default).

- 1 = Tag the model object as the target object.

By default, an IDLgrModel object cannot be returned as the target of a SELECT operation since it contains no geometry.

This property is registered as a Boolean property, but it is hidden by default.

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Select target | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TRANSFORM

A 4-by-4 floating-point transformation matrix to be applied to the object. This matrix will be multiplied by its parent's transformation matrix (if the parent has one). The default is the identity matrix. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Model transform | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

# IDLgrModel::Add

The IDLgrModel::Add procedure method adds a child to this Model.

## Syntax

*Obj* -> [IDLgrModel::]Add, *Object* [, /ALIAS] [, POSITION=*index*]

## Arguments

### Object

An instance of an atomic graphic object or another model object to be added to the model object.

## Keywords

### ALIAS

Set this keyword to a nonzero value to indicate that an alias—rather than the object itself—is to be added to the model. With this keyword you can add the same object to multiple models without duplicating that object and its children. If this keyword is set, the PARENT keyword on the object being added will not change. Furthermore, if this keyword is set, the object being added will not be destroyed when the model is destroyed.

### POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

## Version History

Introduced: 5.0

# IDLgrModel::Cleanup

The IDLgrModel::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrModel::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrModel::Draw

The IDLgrModel::Draw procedure method draws the specified picture to the specified graphics destination. *This method is provided for purposes of sub-classing only, and is intended to be called only from the Draw method of a subclass of IDLgrModel.*

**Note**

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

## Syntax

*Obj* -> [IDLgrModel::]Draw, *Destination*, *Picture*

## Arguments

### Destination

The destination object (IDLgrBuffer, IDLgrClipboard, IDLgrPrinter, or IDLgrWindow) to which the specified view object will be drawn.

### Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn.

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrModel::GetByName

The IDLgrModel::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

**Note**

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

## Syntax

*Result* = *Obj* -> [IDLgrModel::]GetByName(*Name*)

## Return Value

Returns the object reference to the named object or a null object reference.

## Arguments

### Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX file system. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of object3 would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrModel::GetCTM

The IDLgrModel::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrModel::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*] )

## Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the model object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrModel::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrModel::GetProperty

The IDLgrModel::GetProperty procedure method retrieves the value of a property or group of properties for the model.

## Syntax

*Obj* -> [IDLgrModel::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrModel Properties” on page 3345 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrModel::Init

The IDLgrModel::Init procedure method initializes the model object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrModel' [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrModel::]Init([*PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrModel Properties" on page 3345 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

# IDLgrModel::Reset

The IDLgrModel::Reset procedure method sets the current transform matrix for the model object to the identity matrix.

**Note**

Using this method is functionally identical to the following statement:

```
Obj ->[IDLgrModel::]SetProperty, TRANSFORM=IDENTITY(4)
```

## Syntax

*Obj* -> [IDLgrModel::]Reset

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrModel::Rotate

The IDLgrModel::Rotate procedure method rotates the model about the specified axis by the specified angle. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

## Syntax

*Obj* -> [IDLgrModel::]Rotate, *Axis*, *Angle* [, /PREMULTIPLY]

## Arguments

### Axis

A three-element vector of the form [*x*, *y*, *z*] describing the axis about which the model is to be rotated.

### Angle

The angle (measured in degrees) by which the rotation is to occur.

## Keywords

### PREMULTIPLY

Set this keyword to cause the rotation matrix specified by *Axis* and *Angle* to be pre-multiplied to the model's transformation matrix. By default, the rotation matrix is post-multiplied.

## Version History

Introduced: 5.0

# IDLgrModel::Scale

The IDLgrModel::Scale procedure method scales the model by the specified scaling factors. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

## Syntax

*Obj* -> [IDLgrModel::]Scale, *Sx, Sy, Sz* [, /PREMULTIPLY]

## Arguments

### Sx, Sy, Sz

The scaling factors in the *x*, *y*, and *z* dimensions by which the model is to be scaled.

## Keywords

### PREMULTIPLY

Set this keyword to cause the scaling matrix specified by *Sx, Sy, Sz* to be pre-multiplied to the model's transformation matrix. By default, the scaling matrix is post-multiplied.

## Version History

Introduced: 5.0

# IDLgrModel::SetProperty

The IDLgrModel::SetProperty procedure method sets the value of a property or group of properties for the model.

## Syntax

*Obj* -> [IDLgrModel::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrModel Properties” on page 3345 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrModel::Translate

The IDLgrModel::Translate procedure method translates the model about the specified axis by the specified translation offsets. IDL computes and maintains the resulting transform matrix in double-precision floating-point.

## Syntax

*Obj* -> [IDLgrModel::]Translate, *Tx, Ty, Tz* [, /PREMULTIPLY]

## Arguments

### Tx, Ty, Tz

The offsets in *X*, *Y*, and *Z*, respectively, by which the model is to be translated.

## Keywords

### PREMULTIPLY

Set this keyword to cause the translation matrix specified by *Tx, Ty, Tz* to be pre-multiplied to the model's transformation matrix. By default, the translation matrix is post-multiplied.

## Version History

Introduced: 5.0

# IDLgrMPEG

An IDLgrMPEG object creates an MPEG movie file from an array of image frames.

**Note**

The MPEG standard does not allow movies with odd numbers of pixels to be created.

**Note**

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

## Superclasses

IDLitComponent

## Creation

See "IDLgrMPEG::Init" on page 3377.

## Properties

Objects of this class have the following properties. See "IDLgrMPEG Properties" on page 3368 for details on individual properties.

- ALL
- BITRATE
- DIMENSIONS
- FILENAME
- FORMAT
- FRAME_RATE
- IFRAME_GAP
- INTERLACED
- MOTION_VEC_LENGTH
- QUALITY
- SCALE

- STATISTICS
- TEMP_DIRECTORY

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrMPEG::Cleanup
- IDLgrMPEG::GetProperty
- IDLgrMPEG::Init
- IDLgrMPEG::Put
- IDLgrMPEG::Save
- IDLgrMPEG::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.1

# IDLgrMPEG Properties

IDLgrMPEG objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrMPEG::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrMPEG::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrMPEG::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## BITRATE

A double-precision floating-point value to specify the MPEG movie bit rate. Higher bit rates will create higher quality MPEGs but will increase file size. The following table describes the valid values:

| MPEG Version | Range |
|---|---|
| MPEG 1 | 0.1 to 104857200.0 |
| MPEG 2 | 0.1 to 429496729200.0 |

*Table 8-5: BITRATE Value Range*

Set this property to 0.0 (the default setting) to indicate that IDL should compute the BITRATE value based upon the value you have specified for the QUALITY property. The value of BITRATE returned by IDLgrMPEG::GetProperty is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

**Note**

Only use the BITRATE property if changing the QUALITY property value does not produce the desired results. It is highly recommended to set the BITRATE to at least several times the frame rate to avoid unusable MPEG files or file generation errors.

| **Property Type** | Floating-point | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DIMENSIONS

A two-element integer array specifying the dimensions (in pixels) of each of the images to be used as frames for the movie. If this property is not specified, the dimensions of the first image loaded will be used. Once IDLgrMPEG::Put has been called, this property can no longer be set.

**Note**

When creating MPEG files, you must be aware of the capabilities of the MPEG decoder you will be using to view it. Some decoders only support a limited set of sampling and bitrate parameters to normalize computational complexity, buffer size, and memory bandwidth. For example, the Windows Media Player supports a limited set of sampling and bitrate parameters. In this case, it is best to use 352 x 240 x 30 fps or 352 x 288 x 25 fps when determining the dimensions and frame rate for your MPEG file. When opening a file in Windows Media Player that does not use these dimensions, you will receive a “Bad Movie File” error message. The file is not “bad”, this decoder just doesn’t support the dimensions of the MPEG.

| **Property Type** | Integer array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## FILENAME

A string that represents the name of the file in which the encoded MPEG sequence is to be stored. The default is `'idl.mpg'`.

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## FORMAT

A Boolean value that specifies the type of MPEG encoding to use:

- 0 = MPEG1 (the default)
- 1 = MPEG2

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## FRAME_RATE

An integer value that specifies the frame rate used in creating the MPEG file:

| Value | Descriptions |
|---|---|
| 1 | 23.976 frames/sec: NTSC encapsulated film rate |
| 2 | 24 frames/sec: Standard international film rate |
| 3 | 25 frames/sec: PAL video frame rate |
| 4 | 29.97 frames/sec: NTSC video frame rate |
| 5 | 30 frames/sec: NTSC drop frame video frame rate (the default) |
| 6 | 50 frames/sec: Double frame rate/progressive PAL |
| 7 | 59.94 frames/sec: Double frame rate NTSC |
| 8 | 60 frames/sec: Double frame rate NTSC drop frame video |

*Table 8-6: FRAME_RATE Values*

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## IFRAME_GAP

A positive integer value that specifies the number of frames between I frames to be created in the MPEG file. I frames are full-quality image frames that may have a number of predicted or interpolated frames between them.

Set this property to 0 (the default setting) to indicate that IDL should compute the IFRAME_GAP value based upon the value you have specified for the QUALITY property. The value of IFRAME_GAP returned by IDLgrMPEG::GetProperty is either the value computed by IDL from the QUALITY value or the last non-zero valid value stored in this property.

**Note**

Only use the IFRAME_GAP property if changing the QUALITY property value does not produce the desired results.

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## INTERLACED

A Boolean value that indicates whether frames in the encoded MPEG file should be interlaced.

- 0 = Non-interlaced (the default)
- 1 = Interlaced

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## MOTION_VEC_LENGTH

An integer value that specifies the length of the motion vectors to be used to generate predictive frames. The following table describes the valid values:

| Value | Description |
|---|---|
| 1 | Small motion vectors. |
| 2 | Medium motion vectors. |
| 3 | Large motion vectors. |

*Table 8-7: MOTION_VEC_LENGTH Values*

0 (the default setting) indicates that IDL should compute the MOTION_VEC_LENGTH value based upon the value you have specified for the QUALITY property. The value of MOTION_VEC_LENGTH returned by IDLgrMPEG::GetProperty is either the value computed by IDL from the QUALITY value or the last non-zero value stored in this property.

**Note**

Only use the MOTION_VEC_LENGTH property if changing the QUALITY value does not produce the desired results.

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## QUALITY

An integer value between 0 (low quality) and 100 (high quality), inclusive, that specifies the quality at which the MPEG stream is to be stored. Higher quality values result in lower rates of time compression and less motion prediction which provide higher quality MPEGs but with substantially larger file size. Lower quality factors may result in longer MPEG generation times. The default is 50.

**Note**

Since MPEG uses JPEG (lossy) compression, the original picture quality cannot be reproduced even when setting QUALITY to its highest setting.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SCALE

A two-element floating-point vector, [*xscale*, *yscale*], indicating the scale factors to be stored with the MPEG file as hints for playback. The default is [1.0, 1.0], indicating that the movie should be played back at the dimensions of the stored image frames.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## STATISTICS

A Boolean value that determines whether to save statistical information about MPEG encoding for the supplied image frames in a file when the IDLgrMPEG::Save method is called. The information will be saved in a file with a name that matches that specified by the FILENAME property, with the extension "`.stat`".

- 0 = Statistics are not saved (the default).
- 1 = Save statistics.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TEMP_DIRECTORY

A string value that specifies the directory in which to place temporary files while creating the MPEG movie file. The default value is platform specific.

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLgrMPEG::Cleanup

The IDLgrMPEG::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrMPEG::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrMPEG::GetProperty

The IDLgrMPEG::GetProperty procedure method retrieves the value of a property or group of properties for the MPEG object.

## Syntax

*Obj* -> [IDLgrMPEG::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrMPEG Properties” on page 3368 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.1

# IDLgrMPEG::Init

The IDLgrMPEG::Init function method initializes the MPEG object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

**Note**

MPEG support in IDL requires a special license. For more information, contact your RSI sales representative or technical support.

## Syntax

*Obj* = OBJ_NEW('IDLgrMPEG' [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrMPEG::]Init([*PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrMPEG Properties" on page 3368 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.1

# IDLgrMPEG::Put

The IDLgrMPEG::Put procedure method puts a given image into the MPEG sequence at the specified frame. Note that all images in a given MPEG movie must have matching dimensions. If no dimensions were explicitly specified when the MPEG object was initialized, the dimensions will be set according to the dimensions of the first image.

## Syntax

*Obj* -> [IDLgrMPEG::]Put, *Image*[, *Frame*]

## Arguments

### Image

An instance of an IDLgrImage object or a *m* x *n* or 3 x *m* x *n* array representing the image to be loaded at the given frame.

### Frame

An integer specifying the index of the frame at which the image is to be added. Frame indices start at zero. If *Frame* is not supplied, the frame number used will be one more than the last frame that was put. Frame number need not be consecutive; in case of a gap in frame numbers, the frame before the gap is repeated to fill the space.

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrMPEG::Save

The IDLgrMPEG::Save procedure method encodes and saves the MPEG sequence to the specified filename.

**Note**

The MPEG standard does not allow movies with odd numbers of pixels to be created.

## Syntax

*Obj* -> [IDLgrMPEG::]Save [, FILENAME=*string*]

## Arguments

None

## Keywords

### FILENAME

Set this keyword to a string representing the name of the file in which the encoded MPEG sequence is to be stored. The default is `idl.mpg`.

### Obsolete Keywords

The following keywords are obsolete:

- CREATOR_TYPE

For information on obsolete keywords, See Appendix I, “Obsolete Features”.

## Version History

Introduced: 5.1

# IDLgrMPEG::SetProperty

The IDLgrMPEG::SetProperty procedure method sets the value of a property or group of properties for the MPEG object.

## Syntax

*Obj* -> [IDLgrMPEG::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under "IDLgrMPEG Properties" on page 3368 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.1

# IDLgrPalette

A palette object represents a color lookup table that maps indices to red, green, and blue values.

## Superclasses

This class has no superclass.

## Creation

See “IDLgrPalette::Init” on page 3390.

## Properties

Objects of this class have the following properties. See “IDLgrPalette Properties” on page 3384 for details on individual properties.

- ALL
- BLUE_VALUES
- BOTTOM_STRETCH
- GAMMA
- GREEN_VALUES
- N_COLORS
- RED_VALUES
- TOP_STRETCH

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has this following methods:

- IDLgrPalette::Cleanup
- IDLgrPalette::GetRGB
- IDLgrPalette::GetProperty
- IDLgrPalette::Init

- IDLgrPalette::LoadCT
- IDLgrPalette::NearestColor
- IDLgrPalette::SetRGB
- IDLgrPalette::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrPalette Properties

IDLgrPalette objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrPalette::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrPalette::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrPalette::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure that contains the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## BLUE_VALUES

A byte vector containing the blue values for the color palette. Setting this value is the same as specifying the *aBlue* argument to the IDLgrPalette::Init method.

| | | | |
|---|---|---|---|
| **Property Type** | Byte vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## BOTTOM_STRETCH

An integer value in the range of 0 ≤ *Value* ≤ 100 to indicate what percentage of the palette entries at the bottom of the palette should be filled with the value of the first palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at this entry and ending at the entry specified by the value of the TOP_STRETCH property. The default is 0 (zero).

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GAMMA

A floating-point value that indicates the gamma value to be applied to the color palette. This value should be in the range of 0.1 ≤ *Gamma* ≤ 10.0. The default is 1.0.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GREEN_VALUES

A byte vector containing the green values for the color palette. Setting this value is the same as specifying the *aGreen* argument to the IDLgrPalette::Init method.

| | | | |
|---|---|---|---|
| **Property Type** | Byte-vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## N_COLORS

An integer value that determines the number of elements in the color palette.

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## RED_VALUES

A byte vector containing the red values for the color palette. Setting this value is the same as specifying the *aRed* argument to the IDLgrPalette::Init method.

| **Property Type** | Byte vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TOP_STRETCH

A floating-point value in the range of $0 \leq Value \leq 100$ to indicate what percentage of the palette entries at the top of the palette should be filled with the value of the last palette entry. The entire range of red, green, and blue values will be compressed to fit within the range of palette entries beginning at the entry specified by the value of the BOTTOM_STRETCH property and ending at this entry. The default is 0 (zero).

| **Property Type** | Floating-point | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLgrPalette::Cleanup

The IDLgrPalette::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrPalette::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPalette::GetRGB

The IDLgrPalette::GetRGB function method returns the RGB values contained in the palette at the given index. The returned value is a three-element vector of the form [red, green, blue].

## Syntax

*Result* = *Obj* -> [IDLgrPalette::]GetRGB(*Index*)

## Return Value

Returns the RGB values contained in the palette at the given index.

## Arguments

### Index

The index whose RGB values are desired. This value should be in the range of $0 \leq Index < N\_COLORS$, where N_COLORS is the number of elements in the color palette, as returned by the N_COLORS keyword to the IDLgrPalette:GetProperty method.

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPalette::GetProperty

The IDLgrPalette::GetProperty procedure method retrieves the value of a property or group of properties for the palette.

## Syntax

*Obj* -> [IDLgrPalette::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under "IDLgrPalette Properties" on page 3384 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

## Version History

Introduced: 5.0

# IDLgrPalette::Init

The IDLgrPalette::Init function method initializes a palette object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrPalette', *aRed*, *aGreen*, *aBlue* [, *PROPERTY=value*])

or

*Result* = *Obj*`->` [IDLgrPalette::]Init([*aRed*, *aGreen*, *aBlue*] [, *PROPERTY=value*]) (*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### aRed

A vector containing the red values for the color palette. These values should be within the range of 0 ≤ Value ≤ 255. The number of elements comprising the *aRed* vector must not exceed 256.

### aGreen

A vector containing the green values for the color palette. These values should be within the range of 0 ≤ Value ≤ 255. The number of elements comprising the *aGreen* vector must not exceed 256.

### aBlue

A vector containing the blue values for the color palette. These values should be within the range of 0 ≤ Value ≤ 255. The number of elements comprising the *aBlue* vector must not exceed 256.

## Keywords

Any property listed under "IDLgrPalette Properties" on page 3384 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

# IDLgrPalette::LoadCT

The IDLgrPalette::LoadCT procedure method loads one of the IDL predefined color tables into an IDLgrPalette object.

## Syntax

*Obj* -> [IDLgrPalette::]LoadCT, *TableNum* [, FILENAME=*colortable filename*]

## Arguments

### TableNum

The number of the pre-defined IDL color table to load, from 0 to 40.

## Keywords

### FILE

Set this keyword to the name of a colortable file to be used instead of the file `colors1.tbl` in the IDL distribution. The MODIFYCT procedure can be used to create and modify colortable files.

## Version History

Introduced: 5.0

# IDLgrPalette::NearestColor

The IDLgrPalette::NearestColor function method returns the index of the color in the palette that best matches the given RGB values.

## Syntax

*Result* = *Obj*->[IDLgrPalette::]NearestColor(*Red*, *Green*, *Blue*)

## Return Value

Returns the index of the color in the palette that best matches the given RGB values.

## Arguments

### Red

The red value of the color that should be matched. This value should be within the range of 0 ≤ Value ≤ 255.

### Green

The green value of the color that should be matched. This value should be within the range of 0 ≤ Value ≤ 255.

### Blue

The blue value of the color that should be matched. This value should be within the range of 0 ≤ Value ≤ 255.

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPalette::SetRGB

The IDLgrPalette::SetRGB procedure method sets the color values at a specified index in the palette to the specified Red, Green and Blue values.

## Syntax

*Obj* -> [IDLgrPalette::]SetRGB, *Index*, *Red*, *Green*, *Blue*

## Arguments

### Index

The index within the Palette object to be set. This value should be in the range of $0 \leq Value < N\_COLORS$.

### Red

The red value to set in the color palette.

### Green

The green value to set in the color palette.

### Blue

The blue value to set in the color palette.

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPalette::SetProperty

The IDLgrPalette::SetProperty procedure method sets the value of a property or group of properties for the palette.

## Syntax

*Obj* -> [IDLgrPalette::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrPalette Properties” on page 3384 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrPattern

A pattern object describes which pixels are filled and which are left blank when an area is filled. Pattern objects are used by setting the FILL_PATTERN property of a polygon object equal to the object reference of the pattern object.

## Superclasses

IDLitComponent

## Creation

See “IDLgrPattern::Init” on page 3403.

## Properties

Objects of this class have the following properties. See “IDLgrPattern Properties” on page 3398 for details on individual properties.

- ALL
- ORIENTATION
- PATTERN
- SPACING
- STYLE
- THICK

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has this following methods:

- IDLgrPattern::Cleanup
- IDLgrPattern::GetProperty
- IDLgrPattern::Init
- IDLgrPattern:SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrPattern Properties

IDLgrPattern objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrPattern::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrPattern::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrPattern:SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ORIENTATION

An integer representing the angle (measured in degrees counterclockwise from the horizontal) of the lines used in a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to one.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PATTERN

A 32 x 32 bit array (bitmap) describing the pattern that will be tiled over a polygon when a pattern fill is used. The bitmap must be configured as a 4 x 32 “bitmap byte array” as created by the CVTTOBM function. Each bit that is a 1 is drawn, each bit that is 0 is not drawn. Each bit in this array represents a 1 point by 1 point square area of pixels on the destination device. This property is ignored unless the *Style* argument (or STYLE property) is set to 2.

| | | | |
|---|---|---|---|
| **Property Type** | Integer array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SPACING

A floating-point value representing the distance (measured in points) between the lines used for a Line Fill. This property is ignored unless the *Style* argument (or STYLE property) is set to 1. The default is 2.0 points.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## STYLE

An integer value that specifies the type of pattern, as follows:

- 0 = Solid (default)
- 1 = Line Fill
- 2 = Pattern

This property is the same as the *Style* argument described above.

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## THICK

A floating-point value between 1.0 and 10.0 that specifies the line thickness to be used to draw the pattern lines for a Line Fill, in points. The default is 1.0 points. This property is ignored unless the *Style* argument or STYLE property is set to 1.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLgrPattern::Cleanup

The IDLgrPattern::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrPattern::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPattern::GetProperty

The IDLgrPattern::GetProperty procedure method retrieves the value of a property or group of properties for the pattern.

## Syntax

*Obj* -> [IDLgrPattern::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrPattern Properties” on page 3398 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrPattern::Init

The IDLgrPattern::Init function method initializes the pattern object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrPattern' [, *Style*] [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLgrPattern::]Init([*Style*] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Style

A integer value representing the type of pattern. Valid values are:

- 0 = Solid color (default)
- 1 = Line Fill
- 2 = Pattern

## Keywords

Any property listed under "IDLgrPattern Properties" on page 3398 that contains the word "Yes" in the "Init" column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

# IDLgrPattern:SetProperty

The IDLgrPattern::SetProperty procedure method sets the value of a property or group of properties for the pattern.

## Syntax

*Obj* -> [IDLgrPattern::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrPattern Properties” on page 3398 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrPlot

A plot object creates a set of polylines connecting data points in two-dimensional space.

An IDLgrPlot object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

IDLitComponent

## Creation

See "IDLgrPlot::Init" on page 3426.

## Properties

Objects of this class have the following properties. See "IDLgrPlot Properties" on page 3408 for details on individual properties.

- ALL
- COLOR
- DATAX
- DATAY
- DOUBLE
- HIDE
- HISTOGRAM
- LINESTYLE
- MAX_VALUE
- MIN_VALUE
- NSUM
- PALETTE
- PARENT
- POLAR
- REGISTER_PROPERTIES
- RESET_DATA
- SHARE_DATA
- SYMBOL
- THICK
- USE_ZVALUE
- VERT_COLORS
- XCOORD_CONV
- XRANGE
- YCOORD_CONV

- YRANGE
- ZCOORD_CONV
- ZRANGE
- ZVALUE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrPlot::Cleanup
- IDLgrPlot::GetCTM
- IDLgrPlot::GetProperty
- IDLgrPlot::Init
- IDLgrPlot::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrPlot Properties

IDLgrPlot objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrPlot::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrPlot::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrPlot::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A*x* + B*y* + C*z* + D = 0. Portions of this object that fall in the half space A*x* + B*y* + C*z* + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES keyword of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

The color to be used as the foreground color for this plot. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0].

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DATA

The plot data of any type in a 3 x *n* array, [*DataX*, *DataY, DataZ*].

| **Property Type** | Array of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## DATAX

A vector of any type that specifies the X values to be plotted. This property is the same as the X argument.

| **Property Type** | Vector of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DATAY

A vector of any type that specifies the Y values to be plotted. This property is the same as the Y argument.

| **Property Type** | Vector of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HISTOGRAM

A Boolean value that determines whether to use only horizontal and vertical lines to connect the plotted points.

- 0 = The points are connected using a single straight line (the default)..
- 1 = Use only horizontal and vertical lines to connect the plotted points.

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Histogram plot | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LINESTYLE

An integer value that indicates the line style to be used to draw the plot lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot

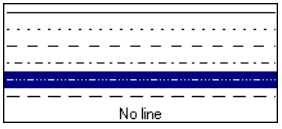
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:



| **Property Type** | LINESTYLE | | |
|---|---|---|---|
| **Name String** | Line style | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## MAX_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. When this property is set, data values greater than the value of MAX_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Maximum value | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## MIN_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of MIN_VALUE

are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Minimum value | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## NSUM

An integer value representing the number of data points to average when plotting. If NSUM is larger than 1, every group of NSUM points is averaged to produce one plotted point. If there are M data points, then M/NSUM points are plotted.

| **Property Type** | INTEGER | | |
|---|---|---|---|
| **Name String** | Number of points to average | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## POLAR

A Boolean value that determines whether to create a polar plot. The *X* and *Y* arguments must both be present. The *X* argument represents the radius, and the *Y* argument represents the angle expressed in radians.

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Polar plot | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XY] properties as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another

object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via a DATA property.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHARE_DATA

An object reference to an object with which data is to be shared by this plot. A plot may only share data with another plot. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SYMBOL

An object reference vector containing instances of the IDLgrSymbol object class. Each symbol in the vector will be drawn at the corresponding plotted point. If there are more points than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a plot, set the SYMBOL property equal to a null object reference.

| | | | |
|---|---|---|---|
| **Property Type** | Object reference vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used to draw the plotted lines, in points. The default is 1.0 points.

In a property sheet, this property appears as follows:

| **Property Type** | THICKNESS | | |
|---|---|---|---|
| **Name String** | Thickness | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## USE_ZVALUE

A Boolean value that determines whether to use the current ZVALUE. The plot is considered three-dimensional if this property is set.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## VERT_COLORS

A vector of colors to be used to draw at each vertex. Color is interpolated between vertices. If there are more plot points than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated. By default, the plot is all drawn in the single color provided by the COLOR property. If the VERT_COLORS is provided, the COLOR property is ignored. Moreover, when VERT_COLORS is used with symbols, the vertex colors override any colors specified by the symbol object or any colors specified by graphic atoms contained in a user-defined symbol.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Vertex colors | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] specifying the range of *x* data coordinates covered by the graphic object. If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] specifying the range of *y* data values covered by the graphic object. If this property is not specified, the minimum and maximum data values are used. IDL converts, maintains, and returns this data as double-precision floating-point.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] specifying the range of *z* data values covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

**Note**

The XRANGE and YRANGE properties can also be retrieved via the GetProperty method; ZRANGE, however, can only be retrieved, not initialized (Init method) or set (SetProperty method).

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZVALUE

A floating-point value to be used as the Z coordinate for the entire plot. By default, 0.0 is used as the Z coordinate.

**Note**

The USE_ZVALUE property needs to be set in order for ZVALUE to take effect.

| **Property Type** | Floating-point | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLgrPlot::Cleanup

The IDLgrPlot::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrPlot::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPlot::GetCTM

The IDLgrPlot::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrPlot::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*] )

## Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the plot object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPlot::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrPlot::GetProperty

The IDLgrPlot::GetProperty procedure method retrieves the value of the property or group of properties for the plot.

## Syntax

*Obj* -> [IDLgrPlot::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrPlot Properties” on page 3408 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrPlot::Init

The IDLgrPlot::Init function method initializes the plot object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrPlot' [, [*X*,] *Y*] [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrPlot::]Init([[*X*,] *Y*] [, *PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector representing the abscissa values to be plotted. If *X* is provided, *Y* is plotted as a function of *X*. The value for this argument is double-precision floating-point if the DOUBLE keyword is set or the inputted value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

### Y

Either a vector of two-element arrays [*x, y*] representing the points to be plotted, or a vector representing the ordinate values to be plotted. If *Y* is a vector of ordinate values and *X* is not specified, *Y* is plotted as a function of the vector index of *Y*. The value for this argument is double-precision floating-point if the DOUBLE keyword is

set or the inputted value is of type DOUBLE. Otherwise it is converted to single-precision floating-point.

## Keywords

Any property listed under “IDLgrPlot Properties” on page 3408 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

# IDLgrPlot::SetProperty

The IDLgrPlot::SetProperty procedure method sets the value of the property or group of properties for the plot.

## Syntax

*Obj* -> [IDLgrPlot::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrPlot Properties” on page 3408 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrPolygon

A polygon object represents one or more polygons that share a given set of vertices and rendering attributes. All polygons must be convex—that is, a line connecting any pair of vertices on the polygon cannot fall outside the polygon. Concave polygons can be converted to a set of convex polygons using the IDLgrTessellator object.

An IDLgrPolygon object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

IDLitComponent

## Creation

See "IDLgrPolygon::Init" on page 3454.

## Properties

Objects of this class have the following properties. See "IDLgrPolygon Properties" on page 3431 for details on individual properties.

- ALL
- BOTTOM
- CLIP_PLANES
- COLOR
- DATA
- DEPTH_OFFSET
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- DOUBLE
- FILL_PATTERN
- HIDDEN_LINES
- HIDE
- LINESTYLE
- NORMALS
- PALETTE
- PARENT
- POLYGONS
- REGISTER_PROPERTIES
- REJECT
- RESET_DATA
- SHADE_RANGE
- SHADING
- SHARE_DATA

- STYLE
- TEXTURE_COORD
- TEXTURE_INTERP
- TEXTURE_MAP
- THICK
- VERT_COLORS
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZERO_OPACITY_SKIP
- ZRANGE
-

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrPolygon::Cleanup
- IDLgrPolygon::GetCTM
- IDLgrPolygon::GetProperty
- IDLgrPolygon::Init
- IDLgrPolygon::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrPolygon Properties

IDLgrPolygon objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrPolygon::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrPolygon::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrPolygon::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## BOTTOM

An RGB color for drawing the bottom of the surface. Set this property to a scalar to draw the bottom with the same color as the top. Setting a bottom color is only supported when the destination device uses RGB color mode.

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Bottom color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A*x* + B*y* + C*z* + D = 0. Portions of this object that fall in the half space A*x* + B*y* + C*z* + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

An RGB or indexed color for drawing polygons. The default color is [0, 0, 0] (black). If the TEXTURE_MAP property is used, the final color is modulated by the texture map pixel values. This property is ignored if the VERT_COLORS property is provided.

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DATA

A *2*-by-*n* or a *3*-by-*n* array of any type which defines, respectively, the 2-D or 3-D vertex data. DATA is equivalent to the optional arguments, X, Y, and Z. This property is stored as double precision floating point values if the property variable is of type DOUBLE or if the DOUBLE property parameter is also specified, otherwise it is converted to single precision floating point.

| | | | |
|---|---|---|---|
| **Property Type** | Array of any type | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

**Note**

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

**Note**

DEPTH_OFFEST has no effect unless the value of the STYLE property is 2 (Filled).

| **Property Type** | INTEGER | | |
|---|---|---|---|
| **Name String** | Depth offset | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object’s depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object’s pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## FILL_PATTERN

An object reference to an IDLgrPattern object (or an array of IDLgrPattern objects) that specifies the fill pattern to use for filling the polygons. By default, FILL_PATTERN is set to a null object reference, specifying a solid fill.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## HIDDEN_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled.

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Remove hidden | | |
| **Get:** No | **Set:** Nos | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value that indicates whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LINESTYLE

An integer value that indicates the line style that should be used to draw the polygon. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE property equal to one of the following integer values:

- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot

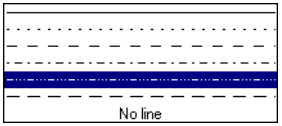
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off).

In a property sheet, this property appears as follows:



| **Property Type** | LINESTYLE | | |
|---|---|---|---|
| **Name String** | Line style | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## NORMALS

A *3*-by-*n* floating-point array of unit polygon normals at each vertex. If this property is not set, vertex normals are computed by averaging shared polygon normals at each vertex. Normals are computed using the Right Hand Rule; that is, if the polygon is facing the viewer, vertices are taken in counterclockwise order. To remove previously specified normals, set NORMALS to a scalar.

**Note**

Computing normals is a computationally expensive operation. Rendering speed increases significantly if you supply the surface normals explicitly. You can compute the array of polygon normals used by this property automatically. See "COMPUTE_MESH_NORMALS" on page 276 for details.

Once you use the NORMALS property in a call to IDLgrPolygon::Init or IDLgrPolygon::SetProperty, you are responsible for that IDLgrPolygon's normals from then on. IDL will not calculate that IDLgrPolygon's normals for you automatically, even if you draw the IDLgrPolygon after vertices or connectivity have been changed.

If you do not use the NORMALS property, IDL calculates normals the first time it draws the IDLgrPolygon. IDL reuses those normals for subsequent draws unless it determines that a fresh recalculation of normals is required, such as if the vertices of the IDLgrPolygon are changed, or you supply new normals via the NORMALS property.

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class). This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## POLYGONS

An integer array of polygon descriptions. A polygon description is an integer or long word array of the form: [*n*, $i_0$, $i_1$, ..., $i_{n-1}$], where *n* is the number of vertices that define the polygon, and $i_0$..$i_{n-1}$ are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices. To ignore an entry in the POLYGONS array, set the vertex count, *n*, to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this property is not specified, a single polygon will be generated.

**Tip**

To ignore an entry in the POLYGONS array, set the entry to 0.

**Note**

The connectivity array described by POLYGONS allows an individual object to contain more than one polygon. Vertex, normal, and color information can be shared by the multiple polygons. Consequently, the polygon object can represent an entire mesh and compute reasonable normal estimates in most cases.

| **Property Type** | Integer array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## REJECT

An integer value to reject polygons as being hidden depending on the orientation of their normals. Select from one of the following values:

- 0 = No polygons are hidden
- 1 = Polygons whose normals point away from the viewer are hidden
- 2 = Polygons whose normals point toward the viewer are hidden

Set this property to zero to draw all polygons regardless of the direction of their normals.

In a property sheet, this property appears as an enumerated list with the following options:

- None
- Normals point away
- Normals point toward

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Polygon rejection | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## RESET_DATA

A Boolean value that determines whether to treat the data provided via the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color index for the brightest pixel. The default is [0, 255]. This

property is ignored when the polygons are drawn to a graphics destination that uses the RGB color model.

| **Property Type** | Integer array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHADING

An integer that represents the type of shading to use:

- 0 = Flat (default): The color of the first vertex in each polygon is used to define the color for the entire polygon. The color has a constant intensity based upon the normal vector.
- 1 = Gouraud: The colors along each line are interpolated between vertex colors, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat
- Gouraud

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Shading | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## SHARE_DATA

An object reference to an object with which data is to be shared by this polygon(s). Polygons may only share data with another polygons object or a polyline. The

SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## STYLE

An integer value that specifies how the polygon should be drawn:

- 0 = Points: Only vertices are drawn, using either COLOR or VERT_COLORS.
- 1 = Lines: Each polygon is outlined by connecting vertices.
- 2 = Filled (default): The polygon faces are shaded.

In a property sheet, this property appears as an enumerated list with the following options:

- Points
- Lines
- Filled

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Style | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TEXTURE_COORD

A 2 by *n* array containing the texture map coordinates, where *n* is the number of polygon vertices. Each two-element entry in this array specifies the texture coordinates for the corresponding vertex in the vertex list. One texture coordinate pair should exist for each vertex. Use this property in conjunction with the TEXTURE_MAP property to wrap images over 2-D and 3-D polygons. Default coordinates are not provided.

Texture coordinates are normalized. This means that the *m* x *n* image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via TEXTURE_MAP is a 256 x 256 array, and we want to map the image into a square two units on each side. To completely fill the square with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [1,1], [0,1]]
```

To fill the square with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [2,2], [0,2]]
```

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TEXTURE_INTERP

A Boolean value that indicates whether bilinear sampling is to be used for texture mapping an image onto the polygon(s). The default is nearest neighbor sampling.

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Bilinear

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Texture interpolation | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TEXTURE_MAP

An object reference to an IDLgrImage object to be texture mapped onto the polygons. The tiling or mapping of the texture is defined expressly by TEXTURE_COORD. If this property is omitted, polygons are filled with the color specified by the COLOR or VERT_COLORS property. If both TEXTURE_MAP and COLORS or VERT_COLORS properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the COLOR property should be set equal to [255,255,255].) To remove a texture map, set TEXTURE_MAP equal to a null object reference.

Setting TEXTURE_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrPolygon object. If an alpha

channel is present in the IDLgrImage object, IDL blends the texture using the blend function src=alpha and dst=1 – alpha, which corresponds to a BLEND_FUNCTION of (3,4) as described for the IDLgrImage object.

If the width and/or height of the provided image is not an exact power of two, then the texture map will consist of the given image pixel values resampled to the nearest larger dimensions that are exact powers of two.

**Note**

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

**Note**

Texture mapping is applied to all styles that are set by the STYLE property.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Texture map | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points or the thickness of the lines to be drawn when STYLE is set to either 0 (Points) or 1 (Lines), in points. The default is 1.0 points.

**Note**

The value of this property is ignored if STYLE is set to 2 (Filled).

In a property sheet, this property appears as follows:

| **Property Type** | THICKNESS | | |
|---|---|---|---|
| **Name String** | Thickness | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## VERT_COLORS

A vector of colors to be used to draw at each vertex. Color is interpolated between vertices if SHADING is set to 1 (Gouraud). If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated. By default, the polygons are all drawn in the single color provided by the COLOR property. To remove vertex colors, set VERT_COLORS to a scalar.

**Note**

If the polygon object is being rendered on a destination device that uses the Indexed color model, and the view that contains the polygon also contains one or more light objects, the VERT_COLORS property is ignored and the SHADE_RANGE property is used instead.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Vertex colors | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZERO_OPACITY_SKIP

A Boolean value that makes it possible to gain finer control over the rendering of textured polygon pixels (texels) with an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity.

- 1 = Any texels are “skipped” and not rendered at all (the default).
- 0 = The Z-buffer is updated for these pixels and the display image is not affected as noted above.

By updating the Z-buffer without updating the display image, the polygon can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

**Note**

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel.

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Skip zero opacity | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrPolygon::Cleanup

The IDLgrPolygon::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrPolygon::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPolygon::GetCTM

The IDLgrPolygon::GetCTM The IDLgrPolygon::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrPolygon::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*] )

## Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polygon object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolygonl::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrPolygon::GetProperty

The IDLgrPolygon::GetProperty procedure method retrieves the value of the property or group of properties for the polygons.

## Syntax

*Obj* -> [IDLgrPolygon::]GetProperty[, *PROPERTY=variable*]

## Arguments

There are no arguments for this methods.

## Keywords

Any property listed under "IDLgrPolygon Properties" on page 3431 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

## Version History

Introduced: 5.0

# IDLgrPolygon::Init

The IDLgrPolygon::Init function method initializes the polygons object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrPolygon' [, *X* [, *Y*[, *Z*]]] [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrPolygon::]Init([*X*, [*Y*, [*Z*]]] [, *PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector argument providing the X coordinates of the vertices. The vector must contain at least three elements. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values.

This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

### Y

A vector argument providing the Y coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

### Z

A vector argument providing the Z coordinates of the vertices. The vector must contain at least three elements. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is converted to single precision floating point.

## Keywords

Any property listed under “IDLgrPolygon Properties” on page 3431 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

# IDLgrPolygon::SetProperty

The IDLgrPolygon::SetProperty procedure method sets the value of the property or group of properties for the polygons.

## Syntax

*Obj* -> [IDLgrPolygon::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrPolygon Properties” on page 3431 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrPolyline

A polyline object represents one or more polylines that share a set of vertices and rendering attributes.

An IDLgrPolyline object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

IDLitComponent

## Creation

See "IDLgrPolyline::Init" on page 3479.

## Properties

Objects of this class have the following properties. See "IDLgrPolyline Properties" on page 3459 for details on individual properties.

- ALL
- COLOR
- DEPTH_TEST_DISABLE
- DEPTH_WRITE_DISABLE
- HIDE
- LABEL_OFFSETS
- LABEL_POLYLINES
- LINESTYLE
- PARENT
- REGISTER_PROPERTIES
- SHADING
- SYMBOL
- USE_LABEL_COLOR
- CLIP_PLANES
- DATA
- DEPTH_TEST_FUNCTION
- DOUBLE
- LABEL_NOGAPS
- LABEL_OBJECTS
- LABEL_USE_VERTEX_COLOR
- PALETTE
- POLYLINES
- RESET_DATA
- SHARE_DATA
- THICK
- USE_LABEL_ORIENTATION

- USE_TEXT_ALIGNMENTS
- VERT_COLORS
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrPolyline::Cleanup
- IDLgrPolyline::GetCTM
- IDLgrPolyline::GetProperty
- IDLgrPolyline::Init
- IDLgrPolyline::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrPolyline Properties

IDLgrPolyline objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrPolyline::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrPolyline::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrPolyline::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL..

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## CLIP_PLANES

A 4-by-*N* floating-point array of dimensions that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A$x$ + B$y$ + C$z$ + D = 0. Portions of this object that fall in the half space A$x$ + B$y$ + C$z$ + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects..

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

An RGB or indexed color for drawing polylines. The default color is [0, 0, 0] (black). This property is ignored if the VERT_COLORS property is provided..

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DATA

A 2-by-*n* or a 3-by-*n* floating-point array which defines, respectively, the 2-D or 3-D vertex data. DATA is equivalent to the optional arguments, *X*, *Y*, and *Z*. This property is converted to double-precision floating-point values if the DOUBLE property is set. Otherwise, it is converted to single-precision floating-point..

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.

- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.

- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LABEL_NOGAPS

An integer vector of values indicating whether gaps should be computed for the corresponding label. A zero value indicates that a gap will be computed for the labels; a non-zero value indicates that no gap will be computed for the label. If the number of labels exceeds the number of elements in this vector, the LABEL_NOGAPS values

will be repeated cyclically. By default, gaps are computed for all labels (so that the polyline does not pass through the label)..

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LABEL_OFFSETS

A scalar or vector of floating-point offsets, [t0, t1, …], that indicate the parametric offsets along the length of each polyline (specified via the LABEL_POLYLINES property) at which each label (as specified via the LABEL_OBJECTS property) would be positioned. If LABEL_OFFSETS is set to a scalar less than zero, then the offsets will be automatically computed to be evenly distributed along the length of the polyline. If a scalar value greater than or equal to zero is provided, it is used for all labels. If a vector is provided, the number of offsets must match the number of labels provided via LABEL_OBJECTS. By default, this property is set to the scalar, -1, indicating that the label offsets will be automatically computed..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LABEL_OBJECTS

An object reference (or vector of object references) to specify the labels to be drawn along the polyline path(s). The objects specified via this property must inherit from one of the following classes:

- IDLgrSymbol
- IDLgrText

If a single object is provided, and it is an IDLgrText object, each of its strings will correspond to a label. If a vector of objects is used, any IDLgrText objects should have only a single string; each object will correspond to a label.

If one or more IDLgrText objects are provided, the LOCATION property of the provided text object(s) may be overwritten; position is determined according to the values provided via the LABEL_OFFSETS property. The labels will have the same color as the corresponding polyline (see the COLOR property) unless the

USE_LABEL_COLOR property is specified. The orientation of the label objects USE_LABEL_ORIENTATION property is specified. The horizontal and vertical alignment for any text labels will each default to 0.5 (i.e., centered) unless the USE_TEXT_ALIGNMENTS property is specified.

**Note**

The objects provided via this property will not be destroyed automatically when this IDLgrPolyline is destroyed..

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LABEL_POLYLINES

An integer or integer vector of polyline indices, [P0, P1, …], that indicate which polylines are to be labeled. Pi corresponds to the ith polyline specified via the POLYLINES property. This property is intended to be used in conjunction with the LABEL_OBJECTS property. If a scalar is provided, all labels will be drawn along the single indicated polyline. If a vector is provided, the number of polyline indices must match the number of labels provided via LABEL_OBJECTS.

By default, this property is set to the scalar, 0, indicating that only the first polyline will be labeled.

**Note**

If a given polyline has more than one label, then the corresponding polyline index may appear more than once in the LABEL_POLYLINES vector..

| **Property Type** | Integer or integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LABEL_USE_VERTEX_COLOR

An integer value that indicates whether labels should be colored according to the vertex coloring (if the VERT_COLORS property is set).

- A non-zero value = labels should be colored according to the vertex coloring

- Zero (the default) = the label will be drawn using the color specified via the COLOR property of the polyline object (unless the USE_LABEL_COLOR property is set)..

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LINESTYLE

An integer or array value that indicates the line style to be used to draw the polyline. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE property equal to one of the following integer values:

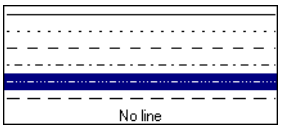
- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1's or 0's in the *bitmask* should be repeated. (That is, if three consecutive 0's appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off)..

In a property sheet, this property appears as follows:



| **Property Type** | LINESTYLE | | |
|---|---|---|---|
| **Name String** | Line style | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp)..

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object..

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## POLYLINES

An integer array of polyline descriptions. A polyline description is an integer or long word array of the form: [*n*, $i_0$, $i_1$, ..., $i_{n-1}$], where *n* is the number of vertices that

define the polyline, and $i_0..i_{n-1}$ are indices into the *X*, *Y*, and *Z* arguments that represent the vertices of the polyline(s). To ignore an entry in the POLYLINES array, set the vertex count, *n*, and all associated indices to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this property is not specified, a single connected polyline will be generated from the *X*, *Y*, and *Z* arguments.

**Note**

The connectivity array described by POLYLINES allows an individual object to contain more than one polyline. Vertex, normal and color information can be shared by the multiple polylines. Consequently, the polyline object can represent an entire mesh and compute reasonable normal estimates in most cases..

| | | | |
|---|---|---|---|
| **Property Type** | Integer array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA property as a new data set unique to this object, rather than overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that

is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via the DATA property. .

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHADING

An integer representing the type of shading to use:

- 0 = Flat (default): The color of the second vertex in a line segment is used to define the color for the entire line segment. The color has a constant intensity based upon the normal vector.
- 1 = Gouraud: The colors along each line are interpolated between vertex colors.

Gouraud shading may be slower than flat shading, but results in a smoother appearance..

In a property sheet, this property appears as an enumerated list with the following options:

- Flat
- Gouraud

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Shading | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## SHARE_DATA

An object reference to an object whose data is to be shared by this polyline. A polyline may only share data with a polygon object or another polyline. The

SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property..

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SYMBOL

An object reference vector containing one or more instances of the IDLgrSymbol object class to indicate the plotting symbols to be used at each vertex of the polyline. If there are more vertices than elements in SYMBOL, the elements of the SYMBOL vector are cyclically repeated. By default, no symbols are drawn. To remove symbols from a polyline, set SYMBOL to a scalar..

| **Property Type** | Object reference vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to be used to draw the polyline, in points. The default is 1.0 points..

In a property sheet, this property appears as follows:

| **Property Type** | THICKNESS | | |
|---|---|---|---|
| **Name String** | Thickness | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## USE_LABEL_COLOR

An integer vector of values to indicate whether the COLOR property value for the corresponding label object is to be used to draw that label. If the number of labels exceeds the number of elements in this vector, the USE_LABEL_COLOR values will be repeated cyclically. By default, this value is zero, indicating that the COLOR property of each label object will be ignored, and the COLOR property for the polyline object will be used instead..

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## USE_LABEL_ORIENTATION

An integer vector of values to indicate whether the orientation of the corresponding label object is to be used to draw that label. For IDLgrText objects, this refers to the BASELINE and UPDIR property values. For IDLgrSymbol objects, this refers to the default (un-rotated) orientation of the symbol. If the number of labels exceeds the number of elements in this vector, the USE_LABEL_ORIENTATION values will be repeated cyclically. By default, USE_LABEL_ORIENTATION is zero, indicating that the orientation will be automatically computed so that the baseline is parallel to the polyline, and the updir is perpendicular to the polyline. .

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## USE_TEXT_ALIGNMENTS

A Boolean value that indicates whether, for any IDLgrText labels (as specified via the LABEL_OBJECTS property), the ALIGNMENT and VERTICAL_ALIGNMENT property values for the given IDLgrText object(s) are to be used to draw those labels. By default, this value is zero, indicating that the ALIGNMENT and VERTICAL_ALIGNMENT properties of the IDLgrText

object(s) will be overwritten with default values (0.5 for each, indicating centered labels)..

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## VERT_COLORS

A vector of colors to be used to draw at each vertex. Color is interpolated between vertices if SHADING is set to 1 (Gouraud). If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated. By default, the polyline is drawn in the single color provided by the COLOR property. When VERT_COLORS is used with symbols, the vertex colors override any colors specified by the symbol object or any colors specified by graphic atoms contained in a user-defined symbol. To remove vertex colors, set VERT_COLORS to a scalar.

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Vertex colors | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, [$s_0$, $s_1$], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrPolyline::Cleanup

The IDLgrPolyline::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrPolyline::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPolyline::GetCTM

The IDLgrPolyline::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrPolyline::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*] )

## Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the polyline object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPolyline::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrPolyline::GetProperty

The IDLgrPolyline::GetProperty procedure method retrieves the value of a property or group of properties for the polylines.

## Syntax

*Obj* -> [IDLgrPolyline::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrPolyline Properties” on page 3459 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrPolyline::Init

The IDLgrPolyline::Init function method initializes the polylines object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrPolyline' [, *X* [, *Y*[, *Z*]]] [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLgrPolyline::]Init([*X*, [*Y*, [*Z*]]] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector providing the X components of the points to be connected. If the Y and Z arguments are not provided, X must be an array of either two or three vectors (i.e., [2,*] or [3,*]), in which case, X[0,*] specifies the X values, X[1,*] specifies the Y values, and X[2,*] specifies the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

### Y

A vector providing the Y coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type

DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

### Z

A vector providing the Z coordinates of the points to be connected. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

## Keywords

Any property listed under “IDLgrPolyline Properties” on page 3459 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

CLIP_PLANES, LABEL_NOGAPS, LABEL_POLYLINES, LABEL_OFFSETS, LABEL_OBJECTS, LABEL_USE_VERTEX_COLOR, USE_LABEL_COLOR, USE_LABEL_ORIENTATION, USE_TEXT_ALIGNMENTS keywords: 5.6

# IDLgrPolyline::SetProperty

The IDLgrPolylines::SetProperty procedure method sets the value of a property or group of properties for the polylines.

## Syntax

*Obj* -> [IDLgrPolyline::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrPolyline Properties” on page 3459 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrPrinter

A printer object represents a hardcopy graphics destination. When a printer object is created, the printer device to which it refers is the default system printer. To change the printer, utilize the printer dialogs (see “DIALOG_PRINTJOB” on page 508 and “DIALOG_PRINTERSETUP” on page 506.)

**Note**

Objects or subclasses of this type can not be saved or restored.

## Superclasses

This class has no superclass.

## Creation

See “IDLgrPrinter::Init” on page 3500.

## Properties

Objects of this class have the following properties. See “IDLgrPrinter Properties” on page 3484 for details on individual properties.

- ALL
- COLOR_MODEL
- DIMENSIONS
- GAMMA
- GRAPHICS_TREE
- LANDSCAPE
- N_COLORS
- N_COPIES
- PALETTE
- PRINT_QUALITY
- QUALITY
- REGISTER_PROPERTIES

- RESOLUTION
- UNITS

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrPrinter::Cleanup
- IDLgrPrinter::Draw
- IDLgrPrinter::GetContiguousPixels
- IDLgrPrinter::GetFontnames
- IDLgrPrinter::GetProperty
- IDLgrPrinter::GetTextDimensions
- IDLgrPrinter::Init
- IDLgrPrinter::NewDocument
- IDLgrPrinter::NewPage
- IDLgrPrinter::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrPrinter Properties

IDLgrPrinter objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrPrinter::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrPrinter::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrPrinter::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## COLOR_MODEL

An integer value that determines the color model to be used for the buffer:

- 0 = RGB (default)
- 1 = Color Index

In a property sheet, this property appears as an enumerated list with the following options:

- RGB

- Indexed

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Color model | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the overall 'drawable' area that may be printed on a page. By default, the dimensions are measured in device units (refer to the UNITS property).

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## GAMMA

An object reference to an IDLgrPalette object whose entries will be used as the gamma correction table for color printing. Gamma correction only applies if COLOR_MODEL=1 (Indexed).

When the color palette (specified via the PALETTE property) is loaded for the printer, if a gamma correction table is provided, then each of the [R,G,B] entries in the color palette will be translated through the gamma correction table. For example, at color index *i*:

```
correctedRed[i] = gammaRed[paletteRed[i]]
correctedGreen[i] = gammaGreen[paletteGreen[i]]
correctedBlue[i] = gammaBlue[paletteBlue[i]]
```

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView that specifies the graphics tree of this object. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will

cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## LANDSCAPE

A Boolean value that indicates whether to produce hardcopy output in landscape mode. The default value of zero indicates Portrait mode.

**Note**

The printer driver may not support the LANDSCAPE option; in general, it is best to use the printer dialogs to set orientation.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## N_COLORS

An integer value that indicates the number of colors (between 2 and 256) to be used if the COLOR_MODEL is set to Indexed (1). This property is ignored if the COLOR_MODEL is set to RGB (0).

| | | | |
|---|---|---|---|
| **Property Type** | INTEGER | | |
| **Name String** | Number of colors | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## N_COPIES

An integer that determines the number of copies of print data to be generated. The default is 1 copy.

**Note**

Your specific printer driver may not support the N_COPIES option. You can also use the printer dialogs to set the number of copies.

| | | | |
|---|---|---|---|
| **Property Type** | Integer | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table if the Indexed color model is used.

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PRINT_QUALITY

An integer value indicating the print quality at which graphics are to be drawn to the printer. Note that the print quality is independent of the rendering quality (as set by the QUALITY property). Valid values are:

- 0 = Low
- 1 = Normal (this is the default)
- 2 = High

Generally, setting the print quality to a lower value will increase the speed of the printing job, but decrease the resolution; setting it to a higher value will cause the printing job to take more time, but will increase the resolution.

**Note**

Some printer drivers may not be able to support different printing qualities. In these cases, the setting of the PRINT_QUALITY property will be quietly ignored.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## QUALITY

An integer value that indicates the rendering quality at which graphics are to be drawn to this destination. Note that the rendering quality is independent of the print quality (as set by the PRINT_QUALITY property). Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium
- High

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Draw quality | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the

object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RESOLUTION

A floating-point vector of the form [*xres*, *yres*] defining the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Resolution | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** Yes |

## UNITS

An integer value that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the drawable area on a page.

**Note**

If you change the value of the UNITS property (using the SetProperty method), IDL will convert the current value of the DIMENSIONS property to the new units.

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLgrPrinter::Cleanup

The IDLgrPrinter::Cleanup procedure method performs all cleanup on the object. If a document is open (that is, if graphics have been draw to the printer), the document is closed and the pending graphics are sent to the current printer.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrPrinter::]Cleanup (*Only in subclass' Cleanup method.*)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPrinter::Draw

The IDLgrPrinter::Draw procedure method draws the given picture to this graphics destination.

**Note**

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

## Syntax

*Obj* -> [IDLgrPrinter::]Draw [, *Picture*] [, VECTOR={ 0 | 1 } ]

## Arguments

### Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn.

## Keywords

### VECTOR

Set this keyword to indicate the type of graphics primitives generated. Valid values include:

- 0 = Bitmap (default)
- 1 = Vector

If VECTOR = 0 (Bitmap), the Draw method renders the scene to a buffer and then copies the buffer to the printer in bitmap format. The bitmap retains the quality of the original image.

If VECTOR = 1 (Vector), the Draw method renders the scene using simple vector operations that result in a representation of the Scene that is scalable to the printer. The vector representation does not retain all the attributes of the original image. The vector representation is sent to the printer.

# Examples

This example demonstrates the process of printing the contents of an IDL graphics display object (a buffer or a window) to an IDLgrPrinter object. The resolution of the printed page is based on the resolution of the screen. The model object in the printer object must be scaled to maintain the same size as displayed on the screen. The location of the view must also be changed to center the display on the page.

```
PRO PrintingAnImage

; Determine the path to the "convec.dat" file.
convecFile = FILEPATH('convec.dat', $
   SUBDIRECTORY = ['examples', 'data'])

; Initialize the parameters of the image with the file.
convecSize = [248, 248]
convecImage = BYTARR(convecSize[0], convecSize[1])

; Open the file, read in the image, and then close the
; file.
OPENR, unit, convecFile, /GET_LUN
READU, unit, convecImage
FREE_LUN, unit

; Initialize the display objects.
windowSize = convecSize
oWindow = OBJ_NEW('IDLgrWindow', RETAIN = 2, $
   DIMENSIONS = windowSize, $
   TITLE = 'Earth Mantle Convection')
oView = OBJ_NEW('IDLgrView', $
   VIEWPLANE_RECT = [0., 0., windowSize])
oModel = OBJ_NEW('IDLgrModel')

; Initialize the image object with its palette.
oPalette = OBJ_NEW('IDLgrPalette')
oPalette -> LOADCT, 27
oImage = OBJ_NEW('IDLgrImage', convecImage, $
   PALETTE = oPalette)

; Add image to model, which is added to the view, and
; then the view is displayed in the window.
oModel -> Add, oImage
oView -> Add, oModel
oWindow -> Draw, oView

; Determine the centimeter measurements of the image
; on the screen.
oWindow -> GetProperty, RESOLUTION = screenResolution
```

```
windowSizeCM = windowSize*screenResolution

; Initialize printer destination object.
oPrinter = OBJ_NEW('IDLgrPrinter', PRINT_QUALITY = 2, $
   QUALITY = 2)

; Obtain page parameters to determine the page
; size in centimeters.
oPrinter -> GetProperty, DIMENSIONS = pageSize, $
   RESOLUTION = pageResolution
pageSizeCM = pageSize*pageResolution

; Calculate a ratio between screen size and page size.
pageScale = windowSizeCM/pageSizeCM

; Use ratio to scale the model within the printer to the
; same size as the model on the screen.
oModel -> Scale, pageScale[0], pageScale[1], 1.

; Determine the center of the page and the image in
; pixels.
centering = ((pageSizeCM - windowSizeCM)/2.) $
   /pageResolution

; Move the view to center the image.
oView -> SetProperty, LOCATION = centering

; Display the view within the printer destination.
oPrinter -> Draw, oView
oPrinter -> NewDocument

; Cleanup object references.
OBJ_DESTROY, [oPrinter, oView, oPalette]

END
```

## Version History

Introduced: 5.0

# IDLgrPrinter::GetContiguousPixels

The IDLgrPrinter::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj -> GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

## Syntax

*Result* = *Obj* -> [IDLgrPrinter::]GetContiguousPixels()

## Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPrinter::GetFontnames

The IDLgrPrinter::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix H, "Fonts" for more information.

## Syntax

*Result* = *Obj* -> [IDLgrPrinter::]GetFontnames( *FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*] )

## Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

## Arguments

### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

## Keywords

### IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

Introduced: 5.0

# IDLgrPrinter::GetProperty

The IDLgrPrinter::GetProperty procedure method retrieves the value of a property or group of properties for the printer.

## Syntax

*Obj* -> [IDLgrPrinter::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under "IDLgrPrinter Properties" on page 3484 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

## Version History

Introduced: 5.0

# IDLgrPrinter::GetTextDimensions

The IDLgrPrinter::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

## Syntax

*Result* = *Obj* ->[IDLgrPrinter::]GetTextDimensions( *TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*] )

## Return Value

Returns a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units.

## Arguments

### TextObj

The object reference to a text or axis object for which the text dimensions are requested.

## Keywords

### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If

this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrPrinter::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## Version History

Introduced: 5.0

# IDLgrPrinter::Init

The IDLgrPrinter::Init function method initializes the printer object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrPrinter' [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrPrinter::]Init([*PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrPrinter Properties" on page 3484 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

# IDLgrPrinter::NewDocument

The IDLgrPrinter::NewDocument procedure method closes the current document (a page or group of pages), which causes any pending output to be sent to the printer, finishing the printer job.

## Syntax

*Obj* -> [IDLgrPrinter::]NewDocument

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPrinter::NewPage

The IDLgrPrinter::NewPage procedure method issues a new page command to the printer.

## Syntax

*Obj* -> [IDLgrPrinter::]NewPage

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrPrinter::SetProperty

The IDLgrPrinter::SetProperty procedure method sets the value of a property or group of properties for the printer.

## Syntax

*Obj* -> [IDLgrPrinter::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrPrinter Properties” on page 3484 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrROI

The IDLgrROI object class is an object graphics representation of a region of interest.

## Superclasses

IDLanROI

IDLitComponent

## Creation

See “IDLgrROI::Init” on page 3518.

## Properties

Objects of this class have the following properties. See “IDLgrROI Properties” on page 3507 for details on individual properties.

- ALL
- CLIP_PLANES
- COLOR
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- DOUBLE
- HIDE
- LINESTYLE
- PALETTE
- REGISTER_PROPERTIES
- STYLE
- SYMBOL
- THICK
- XCOORD_CONV
- XRANGE

- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

The IDLgrROI object class has the following methods:

- IDLgrROI::Cleanup
- IDLgrROI::GetProperty
- IDLgrROI::Init
- IDLgrROI::PickVertex
- IDLgrROI::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.3

# IDLgrROI Properties

IDLgrROI objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrROI::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrROI::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrROI::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure with the values of all of the properties associated with the state of this object. State information about the object may include things like color, line style, etc., but not vertex data or user values.

**Note**

The fields in this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A*x* + B*y* + C*z* + D = 0. Portions of this object that fall in the half space A*x* + B*y* + C*z* + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

A vector that indicates an RGB or indexed color for drawing the region. The default color is [0, 0, 0].

In a property sheet, this property appears as a color property.

| | | | |
|---|---|---|---|
| **Property Type** | COLOR | | |
| **Name String** | Color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property

is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## HIDE

A Boolean value indicating whether this region should be drawn:

- 0 = draw the region (the default)
- 1 = do not draw the region

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LINESTYLE

An integer that indicates the line style to be used to draw the region. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern. The valid values for the pre-defined line styles are:

- 0 = solid (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash

- 6 = no line drawn

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used for Object Graphics destinations using the RGB color model. In this case, if the color value for the region is specified as a color index value, this palette is used to look up the color for the region. If the PALETTE property is not set, the destination object PALETTE property is used, which defaults to a gray scale ramp.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## STYLE

An integer value that indicates the geometrical primitive to use to represent the region when displayed. Valid values include:

- 0 = points
- 1 = open polyline

- 2 = closed polyline (the default)

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SYMBOL

An object reference to an IDLgrSymbol object for the symbol used for display when STYLE = 0 (points). By default, a dot is used.

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## THICK

A floating-point value between 1.0 and 10.0, specifying the size of the points, or the thickness of the lines, measured in points. The default is 1.0 points.

In a property sheet, this property appears as follows:

| **Property Type** | THICKNESS | | |
|---|---|---|---|
| **Name String** | Thickness | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## XCOORD_CONV

A vector, $[s_0, s_1]$, of scaling factors used to convert *X* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max} - X_{min}),\ 1.0/(X_{max} - X_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Double-precision floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert *Y* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}),\ 1.0/(Y_{max} - Y_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}),\ 1.0/(Z_{max} - Z_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrROI::Cleanup

The IDLgrROI::Cleanup procedure method performs all cleanup for a region of interest object.

**Note**

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrROI::]Cleanup (In a subclass' Cleanup method only.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.3

# IDLgrROI::GetProperty

The IDLgrROI::GetProperty procedure method retrieves the value of a property or group of properties for the Object Graphics region.

## Syntax

*Obj* -> [IDLgrROI::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under "IDLgrROI Properties" on page 3507 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

## Version History

Introduced: 5.3

# IDLgrROI::Init

The IDLgrROI::Init function method initializes an Object Graphics region of interest.

**Note**

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW( 'IDLgrROI' [, *X*[, *Y*[, *Z*]]] [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrROI::]Init([*X*[, *Y*[, *Z*]]] [, *PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector providing the X components of the vertices for the region. If the Y and Z arguments are not specified, X must be a two-dimensional array with the leading dimension either 2 or 3 ([2, *] or [3, *]), in which case, X[0, *] represents the X values, X[1, *] represents the Y values, and X[2, *] represents the Z values. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

### Y

A vector providing the Y components of the vertices. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

### Z

A scalar or vector providing the Z components of the vertices. If not provided, Z values default to 0.0. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero. Otherwise it is converted and stored as single precision floating point.

## Keywords

Any property listed under “IDLgrROI Properties” on page 3507 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.3

CLIP_PLANES keyword: 5.6

# IDLgrROI::PickVertex

The IDLgrROI::PickVertex function method picks a vertex of the region which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

## Syntax

*Result* = *Obj* -> [IDLgrROI::]PickVertex( *Dest*, *View*, *Point* [, PATH=*objref*] )

## Return Value

Returns the index of the nearest region vertex. If two or more vertices are equally nearest to the point, the smallest index of those vertices is returned.

## Arguments

### Dest

An object reference to an IDLgrWindow or IDLgrBuffer for which the pick is to occur.

### View

An object reference to the IDLgrView containing this region.

### Point

A two-element vector, [*x*, *y*], representing the device location used for picking a nearest vertex.

## Keywords

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected vertex is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

## Version History

Introduced: 5.3

# IDLgrROI::SetProperty

The IDLgrROI::SetProperty procedure method sets the value of a property or group of properties for the Object Graphics region.

## Syntax

*Obj* -> [IDLgrROI::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrROI Properties” on page 3507 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.3

# IDLgrROIGroup

The IDLgrROIGroup object class is an Object Graphics representation of a group of regions of interest.

## Superclasses

IDLanROIGroup.

IDLitComponent

## Creation

See “IDLgrROIGroup::Init” on page 3535.

## Properties

Objects of this class have the following properties. See “IDLgrROIGroup Properties” on page 3525 for details on individual properties.

- ALL
- CLIP_PLANES
- COLOR
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- HIDE
- PARENT
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

The IDLgrROIGroup class has the following methods:

- IDLgrROIGroup::Add
- IDLgrROIGroup::Cleanup
- IDLgrROIGroup::GetProperty
- IDLgrROIGroup::Init
- IDLgrROIGroup::PickRegion
- IDLgrROIGroup::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.3

# IDLgrROIGroup Properties

IDLgrROIGroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrROIGroup::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrROIGroup::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrROIGroup::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure with the values of all of the properties associated with the state of this object.

**Note**

The fields in this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A*x* + B*y* + C*z* + D = 0. Portions of this object that fall in the half space A*x* + B*y* + C*z* + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any x, y, or z coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects..

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

An RGB or indexed color for drawing the region group. The default color is [0,0,0]..

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value indicating whether this region group should be drawn:

- 0 = draw the region group (the default)
- 1 = do not draw the region group.

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object..

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert $X$ coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max} - X_{min}),\ 1.0/(X_{max} - X_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point..

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert $Y$ coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max} - Y_{min}),\ 1.0/(Y_{max} - Y_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max} - Z_{min}),\ 1.0/(Z_{max} - Z_{min})\ ]$$

IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrROIGroup::Add

The IDLgrROIGroup::Add procedure method adds a region to the region group. Only objects of the IDLgrROI class may be added to the group. The regions in the group must all be of the same type: all points, all paths, or all polygons.

## Syntax

*Obj* -> [IDLgrROIGroup::]Add, *ROI*

## Arguments

### ROI

A reference to an instance of the IDLgrROI object class representing the region of interest to add to the group.

## Keywords

Accepts all keywords accepted by the IDLanROIGroup::Add method.

## Version History

Introduced: 5.3

# IDLgrROIGroup::Cleanup

The IDLgrROIGroup::Cleanup procedure method performs all cleanup for an Object Graphics region of interest group object.

**Note**

Cleanup methods are special life cycle methods, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrROIGroup::]Cleanup (In a subclass' Cleanup method only.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.3

# IDLgrROIGroup::GetProperty

The IDLgrROIGroup::Get Property procedure method retrieves the value of a property or group of properties for the region group.

## Syntax

*Obj* -> [IDLgrROIGroup::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrROIGroup Properties” on page 3525 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.3

# IDLgrROIGroup::Init

The IDLgrROIGroup::Init function method initializes an Object Graphics region of interest group object.

**Note**

Init methods are special life cycle methods, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrROIGroup' [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLgrROIGroup::]Init([*PROPERTY=value*])
(*Only in a subclass' Init method*.)

**Note**

Keywords can be used in either form. They are omitted in the second form for brevity.

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrROIGroup Properties" on page 3525 that contains the word "Yes" in the "Init" column of the properties table can be initialized during

object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.3

CLIP_PLANES keyword: 5.6

# IDLgrROIGroup::PickRegion

The IDLgrROIGroup::PickRegion function method picks a region within the group which, when projected onto the given destination device, is nearest to the given 2-D device coordinate.

## Syntax

*Result* = *Obj* -> [IDLgrROIGroup::]PickRegion( *Dest*, *View*, *Point* [, PATH=*objref*] )

## Return Value

Returns the object reference of the nearest region. If two or more regions are equally nearest to the point, the one that was added to the region group first is returned.

## Arguments

### Dest

An object reference to an IDLgrWindow or IDLgrBuffer for which the pick is to occur.

### View

An object reference to the IDLgrView containing this region.

### Point

A two-element vector, [*x*, *y*], representing the device location to use for picking a nearest region.

## Keywords

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a location in the data space of the region. Each path object reference specified with this keyword must contain an alias. The selected region is computed for the version of the object falling within the specified path. If this keyword is not set, the parent properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

## Version History

Introduced: 5.3

# IDLgrROIGroup::SetProperty

The IDLgrROIGroup::Set Property procedure method sets the value of a property or group of properties for the region group.

## Syntax

*Obj* -> [IDLgrROIGroup::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrROIGroup Properties” on page 3525 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.3

# IDLgrScene

A scene object represents the entire scene to be drawn and serves as a container of IDLgrView or IDLgrViewgroup objects.

## Superclasses

TrackBall.

IDLitComponent

## Creation

See “IDLgrScene::Init” on page 3550.

## Properties

Objects of this class have the following properties. See “IDLgrScene Properties” on page 3542 for details on individual properties.

- ALL
- COLOR
- HIDE
- REGISTER_PROPERTIES
- TRANSPARENT

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrScene::Add
- IDLgrScene::Cleanup
- IDLgrScene::GetByName
- IDLgrScene::GetProperty
- IDLgrScene::Init
- IDLgrScene::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrScene Properties

IDLgrScene objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrScene::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrScene::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrScene::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## COLOR

The color to which the scene should be erased before drawing. The color may be specified as a color lookup table index or an RGB vector.

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Background color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

For IDLgrScene, the available properties (and their iTool data types) are:

- HIDE (Boolean)

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## TRANSPARENT

A Boolean value that determines whether to disable window clearing. If this property is not set, the destination object in use by the scene is automatically erased when the scene is initialized.

| | | | |
|---|---|---|---|
| **Property Type** | BOOLEAN | | |
| **Name String** | Transparent | | |
| **Get:** Yes | **Set:** Yes | **Init:** No | **Registered:** Yes |

# IDLgrScene::Add

The IDLgrScene::Add function method verifies that the added item is an instance of an IDLgrView or IDLgrViewgroup object. If it is, IDLgrScene:Add adds the view or viewgroup to the specified scene.

## Syntax

*Obj* -> [IDLgrScene::]Add, *View* [, POSITION=*index*]

## Arguments

### View

An instance of the IDLgrView or IDLgrViewgroup object class.

## Keywords

### POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

## Version History

Introduced: 5.0

# IDLgrScene::Cleanup

The IDLgrScene::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrScene::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrScene::GetByName

The IDLgrScene::GetByName function method finds contained objects by name and returns the object reference to the named object. If the named object is not found, the GetByName function returns a null object reference.

**Note**

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

## Syntax

*Result* = *Obj* -> [IDLgrScene::]GetByName(*Name*)

## Return Value

Returns the object reference to the named object. If the named object is not found, returns a null object reference.

## Arguments

### Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of object3 would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrScene::GetProperty

The IDLgrScene::GetProperty procedure method retrieves the value of a property or group of properties for the contour.

## Syntax

*Obj* -> [IDLgrScene::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrScene Properties” on page 3542 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrScene::Init

The IDLgrScene::Init function method initializes the scene object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrScene' [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrScene::]Init([*PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrScene Properties" on page 3542 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

# IDLgrScene::SetProperty

The IDLgrScene::SetProperty procedure method sets the value of a property or group of properties for the buffer.

## Syntax

*Obj* -> [IDLgrScene::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrScene Properties” on page 3542 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrSurface

A surface object represents a shaded or vector representation of a mesh grid.

An IDLgrSurface object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

IDLitComponent

## Creation

See "IDLgrSurface::Init" on page 3579.

## Properties

Objects of this class have the following properties. See "IDLgrSurface Properties" on page 3555 for details on individual properties.

- ALL
- BOTTOM
- CLIP_PLANES
- COLOR
- DATA
- DATAX
- DATAY
- DATAZ
- DEPTH_OFFSET
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- DOUBLE
- EXTENDED_LEGO
- HIDDEN_LINES
- HIDE
- LINESTYLE
- MAX_VALUE
- MIN_VALUE
- PALETTE
- PARENT
- REGISTER_PROPERTIES
- RESET_DATA
- SHADE_RANGE
- SHADING
- SHARE_DATA
- SHOW_SKIRT
- SKIRT

- STYLE
- TEXTURE_COORD
- TEXTURE_HIGHRES
- TEXTURE_INTERP
- TEXTURE_MAP
- THICK
- USE_TRIANGLES
- VERT_COLORS
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZERO_OPACITY_SKIP
- ZRANGE
-

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrSurface::Cleanup
- IDLgrSurface::GetCTM
- IDLgrSurface::GetProperty
- IDLgrSurface::Init
- IDLgrSurface::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrSurface Properties

IDLgrSurface objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrSurface::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrSurface::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrSurface::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## BOTTOM

An RGB color for drawing the bottom of the surface. Set this property to a scalar to draw the bottom with the same color as the top. Setting a bottom color is only supported when the destination device uses RGB color mode..

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Bottom color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A*x* + B*y* + C*z* + D = 0. Portions of this object that fall in the half space A*x* + B*y* + C*z* + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects..

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

The color to be used as the foreground color for this model. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0]..

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Bottom color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DATA

An array of any type that specifies the surface data..

| **Property Type** | Array of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** | **Init:** | **Registered:** No |

## DATAX

A floating-point vector or a two-dimensional array specifying the X coordinates of the surface grid. This property is the same as the X argument described above. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point..

| **Property Type** | Floating-point vector or array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DATAY

A floating-point vector or a two-dimensional array specifying the Y coordinates of the surface grid. This property is the same as the Y argument described above. This property is stored as double precision floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point..

| **Property Type** | Floating-point vector or array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DATAZ

A two-dimensional floating-point array to display as a surface. This property is the same as the Z argument described above. This property is stored as double precision

floating point values if the property is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point..

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point array | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DEPTH_OFFSET

An integer value that specifies an offset in depth to be used when rendering filled primitives. This offset is applied along the viewing axis, with positive values moving the primitive away from the viewer.

The units are “Z-Buffer units,” where a value of 1 is used to specify a distance that corresponds to a single step in the device’s Z-Buffer.

Use DEPTH_OFFSET to always cause a filled primitive to be rendered slightly deeper than other primitives, independent of model transforms. This is useful for avoiding stitching artifacts caused by rendering lines or polygons on top of other polygons at the same depth.

**Note**

RSI suggests using this feature to remove stitching artifacts and not as a means for “layering” complex scenes with multiple DEPTH_OFFSET values. It is safest to use only a DEPTH_OFFSET value of 0, the default, and one other non-zero value, such as 1. Many system-level graphics drivers are not consistent in their handling of DEPTH_OFFSET values, particularly when multiple non-zero values are used. This can lead to portability problems because a set of DEPTH_OFFSET values may produce better results on one machine than on another. Using IDL’s software renderer will help improve the cross-platform consistency of scenes that use DEPTH_OFFSET.

**Note**

DEPTH_OFFEST has no effect unless the value of the STYLE property is 2 or 6 (Filled or LegoFilled)..

| | | | |
|---|---|---|---|
| **Property Type** | INTEGER | | |
| **Name String** | Depth offset | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.

- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DOUBLE

A Boolean value that indicates whether data provided by any of the input arguments will be stored in this object as using double-precision floating-point format.

- Set this property equal to 1 to convert input data to double-precision floating-point format.
- Set this property equal to 0 to convert input data to single-precision floating-point format.
- If you do not specify a value for this property, no data type conversion will be performed, and the data will be stored with its original precision.

Setting this property may be desirable if the data consists of large integers that cannot be accurately represented in single-precision floating-point arithmetic. This property is also automatically set to 1 if any of the input arguments are stored using a variable of type DOUBLE..

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## EXTENDED_LEGO

A Boolean value that determines whether to force the IDLgrSurface object to display the last row and column of data when lego display styles are selected..

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Show last lego row/column | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDDEN_LINES

A Boolean value that determines whether to draw point and wireframe surfaces using hidden line (point) removal. By default, hidden line removal is disabled..

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Remove hidden lines | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LINESTYLE

An integer value that indicates the line style to use to draw the surface lines. The value can be either an integer value specifying a pre-defined line style, or a two-element vector specifying a stippling pattern.

To use a pre-defined line style, set the LINESTYLE property equal to one of the following integer values:

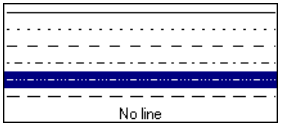
- 0 = Solid line (the default)
- 1 = dotted
- 2 = dashed
- 3 = dash dot
- 4 = dash dot dot dot
- 5 = long dash
- 6 = no line drawn

To define your own stippling pattern, specify a two-element vector [*repeat*, *bitmask*], where *repeat* indicates the number of times consecutive runs of 1’s or 0’s in the *bitmask* should be repeated. (That is, if three consecutive 0’s appear in the *bitmask* and the value of *repeat* is 2, then the line that is drawn will have six consecutive bits turned off.) The value of *repeat* must be in the range $1 \leq repeat \leq 255$.

The *bitmask* indicates which pixels are drawn and which are not along the length of the line. *Bitmask* is most conveniently specified as a 16-bit hexadecimal value.

For example, `LINESTYLE = [2, 'F0F0'X]` describes a dashed line (8 bits on, 8 bits off, 8 bits on, 8 bits off)..

In a property sheet, this property appears as follows:



| **Property Type** | LINESTYLE | | |
|---|---|---|---|
| **Name String** | Line style | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## MAX_VALUE

A double-precision floating-point value that determines the maximum value to be plotted. If this property is present, data values greater than the value of MAX_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Maximum value | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## MIN_VALUE

A double-precision floating-point value that determines the minimum value to be plotted. If this property is present, data values less than the value of MIN_VALUE are treated as missing data and are not plotted. Note that the IEEE floating-point value NaN is also treated as missing data. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Minimum value | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp)..

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object..

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RESET_DATA

A Boolean value that determines whether to treat the data provided via one of the DATA[XYZ] properties as a new data set unique to this object, rather than

overwriting data that is shared by other objects. There is no reason to use this property if the object on which the property is being set does not currently share data with another object (that is, if the SHARE_DATA property is not in use). This property has no effect if no new data is provided via a DATA property. .

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHADE_RANGE

A two-element integer array that specifies the range of pixel values (color indices) to use for shading. The first element is the color index for the darkest pixel. The second element is the color element for the brightest pixel. This value is ignored when the polygons are drawn to a graphics destination that uses the RGB color model..

| **Property Type** | Integer array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHADING

An integer representing the type of shading to use if STYLE is set to 2 (Filled).

- 0 = Flat (default): The color has a constant intensity for each face of the surface, based on the normal vector.
- 1 = Gouraud: The colors are interpolated between vertices, and then along scanlines from each of the edge intensities.

Gouraud shading may be slower than flat shading, but results in a smoother appearance.

In a property sheet, this property appears as an enumerated list with the following options:

- Flat

- Gouraud

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Fill shading | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## SHARE_DATA

An object reference to an object whose data is to be shared by this surface. A surface may only share data with another surface. The SHARE_DATA property is intended for use when data values are not set via an argument to the object's Init method or by setting the object's DATA property..

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SHOW_SKIRT

A Boolean value that determines whether to enable skirt drawing. The default is to disable skirt drawing. .

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Show skirt | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## SKIRT

A floating-point value that determines the *Z* value at which a skirt is to be defined around the array. The *Z* value is expressed in data units; the default is 0.0. If a skirt is defined, each point on the four edges of the surface is connected to a point on the skirt which has the given *Z* value, and the same *X* and *Y* values as the edge point. In addition, each point on the skirt is connected to its neighbor. The skirt value is

ignored if skirt drawing is disabled (see SHOW_SKIRT above). IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Skirt bottom height | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## STYLE

An integer value that indicates the style to be used to draw the surface. Valid values are:

- 0 = Points
- 1 = Wire mesh (the default)
- 2 = Filled
- 3 = RuledXZ
- 4 = RuledYZ
- 5 = Lego
- 6 = LegoFilled: for outline or shaded and stacked histogram-style plots..

In a property sheet, this property appears as an enumerated list with the following options:

- Points
- Wire mesh
- Filled
- Ruled XZ
- Ruled YZ
- Lego
- Lego filled

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Surface style | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TEXTURE_COORD

A 2-by-*n* floating-point array of surface coordinate-texture map coordinate pairs [*s*, *t*] at each vertex., containing the fill pattern array subscripts of each of the *n* polygon vertices. Use this property in conjunction with the TEXTURE_MAP property to warp images over the surface. To stretch (or shrink) the texture map to cover the surface mesh completely, set TEXTURE_COORD to a scalar. By default, IDL stretches (or shrinks) the texture map to cover the surface mesh completely, and sets TEXTURE_COORD to a scalar (-1).

Texture coordinates are normalized. This means that the *m* x *n* image object specified via the TEXTURE_MAP property is mapped into the range [0.0, 0.0] to [1.0, 1.0]. If texture coordinates outside the range [0.0, 0.0] to [1.0, 1.0] are specified, the image object is tiled into the larger range.

For example, suppose the image object specified via TEXTURE_MAP is a 256 x 256 array, and we want to map the image into a square two units on each side. To completely fill the square with a single copy of the image:

```
TEXTURE_COORD = [[0,0], [1,0], [1,1], [0,1]]
```

To fill the square with four tiled copies of the image:

```
TEXTURE_COORD = [[0,0], [2,0], [2,2], [0,2]]
```

Because of the way in which high-resolution textures require modified texture coordinates, if the TEXTURE_COORD property is used, TEXTURE_HIGHRES will be disabled..

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TEXTURE_HIGHRES

A Boolean value that determines whether texture tiling will be used when necessary to maintain the full pixel resolution of the original texture image. This is recommended if IDL is running on modern 3-D hardware and resolution loss due to downscaling becomes problematic. If not set, and the texture map is larger than the maximum resolution supported by the 3-D hardware, the texture is scaled down to the maximum resolution supported by the 3-D hardware on your system. The default value is 0.

**Note**

Because of the way in which high-resolution textures require modified texture coordinates, if you specify the TEXTURE_COORD property, high resolution textures (TEXTURE_HIGHRES) will be disabled..

In a property sheet, this property appears as an enumerated list with the following options:

- No tiling
- LOD tiling
- Tiling

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Texture hires | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TEXTURE_INTERP

A Boolean value that indicates whether bilinear sampling is to be used with texture mapping. The default method is nearest-neighbor sampling..

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Bilinear

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Texture interpolation | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## TEXTURE_MAP

An object reference to an instance of the IDLgrImage object class to be texture mapped onto the surface. If this property is omitted or set to a null object reference, no texture map is applied and the surface is filled with the color specified by the COLOR or VERT_COLORS property. If both TEXTURE_MAP and COLORS or VERT_COLORS properties exist, the color of the texture is modulated by the base color of the object. (This means that for the clearest display of the texture image, the

COLOR property should be set equal to [255,255,255].) By default, the texture map will be stretched (or shrunk) to cover the surface mesh completely.

Setting TEXTURE_MAP to the object reference of an IDLgrImage that contains an alpha channel allows you to create a transparent IDLgrSurface object. If an alpha channel is present in the IDLgrImage object, IDL blends the texture using the blend function src = alpha and dst = 1 - alpha, which corresponds to a BLEND_FUNCTION of (3,4) as described for the IDLgrImage object.

If a texture is provided without texture coordinates, IDLgrSurface generates its own texture mapping coordinates to map the texture onto the surface without resampling artifacts, even if the provided texture image does not have dimensions that are an exact power of two. If texture coordinates are provided, the image is resampled to the nearest larger dimensions that are exact powers of two.

**Note**

Texture mapping is disabled when rendering to a destination object that uses Indexed color mode.

**Note**

Texture mapping is applied to all styles that are set by the STYLE property except Lego and LegoFilled..

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Texture map | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to use to draw surface lines, in points. The default is 1.0 points..

In a property sheet, this property appears as follows:

| **Property Type** | THICKNESS | | |
|---|---|---|---|
| **Name String** | Line thickness | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## USE_TRIANGLES

A Boolean value that determines whether to force the IDLgrSurface object to use triangles instead of quads to draw the surface and skirt..

In a property sheet, this property appears as an enumerated list with the following options:

- Quads
- Triangles

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Draw method | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## VERT_COLORS

A vector of colors to be used to draw at each vertex. Color is interpolated between vertices if SHADING is set to 1 (Gouraud). If there are more vertices than elements in VERT_COLORS, the elements of VERT_COLORS are cyclically repeated. By default, the polygons are all drawn in the single color provided by the COLOR property. If this property is omitted or set to a scalar, vertex colors are removed and the surface is drawn in the color specified by the COLOR property.

**Note**

If the surface object is being rendered on a destination device that uses the Indexed color model, and the view that contains the surface also contains one or more light

objects, the VERT_COLORS property is ignored and the SHADE_RANGE property is used instead..

---

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Vertex colors | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert *X* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, [$s_0$, $s_1$], of scaling factors used to convert *Y* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, [$s_0$, $s_1$], of scaling factors used to convert *Z* coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZERO_OPACITY_SKIP

A Boolean value that determines whether to gain finer control over the rendering of textured surface pixels (texels) by setting an opacity of 0 in the texture map. Texels with zero opacity do not affect the color of a screen pixel since they have no opacity. If this property is set to 1, any texels are “skipped” and not rendered at all. If this property is set to zero, the Z-buffer is updated for these pixels and the display image is not affected as noted above. By updating the Z-buffer without updating the display image, the surface can be used as a *clipping* surface for other graphics primitives drawn after the current graphics object. The default value for this property is 1.

**Note**

This property has no effect if no texture map is used or if the texture map in use does not contain an opacity channel..

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Skip zero opacity | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrSurface::Cleanup

The IDLgrSurface::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrSurface::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrSurface::GetCTM

The IDLgrSurface::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrSurface::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*] )

## Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the surface object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrSurface::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrSurface::GetProperty

The IDLgrSurface::GetProperty procedure method retrieves the value of a property or group of properties for the surface.

## Syntax

*Obj* -> [IDLgrSurface::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrSurface Properties” on page 3555 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrSurface::Init

The IDLgrSurface::Init function method initializes the surface object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrSurface' [, *Z* [, *X*, *Y*]] [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLgrSurface::]Init([*Z* [, *X*, *Y*]] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### X

A vector or two-dimensional array specifying the X coordinates of the grid. If this argument is a vector, each element of X specifies the X coordinates for a column of Z (e.g., X[0] specifies the X coordinate for Z[0, *]). If X is a two-dimensional array, each element of X specifies the X coordinate of the corresponding point in Z ($X_{ij}$ specifies the X coordinate of $Z_{ij}$). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

### Y

A vector or two-dimensional array specifying the Y coordinates of the grid. If this argument is a vector, each element of Y specifies the Y coordinates for a column of Z (e.g., Y[0] specifies the Y coordinate for Z[*, 0]). If Y is a two-dimensional array, each element of Y specifies the Y coordinate of the corresponding point in Z ($Y_{ij}$ specifies the Y coordinate of $Z_{ij}$). This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

### Z

The two-dimensional array to be displayed. If X and Y are provided, the surface is defined as a function of the (X, Y) locations specified by their contents. Otherwise, the surface is generated as a function of the array indices of each element of Z. This argument is stored as double precision floating point values if the argument variable is of type DOUBLE or if the DOUBLE property is non-zero, otherwise it is stored as single precision floating point.

## Keywords

Any property listed under “IDLgrSurface Properties” on page 3555 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

# IDLgrSurface::SetProperty

The IDLgrSurface::SetProperty procedure method sets the value of a property or group of properties for the surface.

## Syntax

*Obj* -> [IDLgrSurface::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrSurface Properties” on page 3555 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrSymbol

A symbol object represents a graphical element that is plotted relative to a particular position.

**Note**

Seven predefined symbols are provided by IDL.

## Superclasses

IDLitComponent

## Creation

See "IDLgrSymbol::Init" on page 3588.

## Properties

Objects of this class have the following properties. See "IDLgrSymbol Properties" on page 3584 for details on individual properties.

- ALL
- COLOR
- DATA
- SIZE
- THICK

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrSymbol::Cleanup
- IDLgrSymbol::GetProperty
- IDLgrSymbol::Init
- IDLgrSymbol::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrSymbol Properties

IDLgrSymbol objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrSymbol::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrSymbol::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrSymbol::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## COLOR

The color used to draw the symbol. The color may be specified as a color lookup table index or as an RGB vector. The default color is the color of the object for which this symbol is being used.

| **Property Type** | Color | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DATA

A Boolean value that determines whether to specify a symbol. This property is equivalent to the *Data* argument.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## SIZE

A one-, two-, or three-element floating-point vector describing the X, Y, and Z scaling factors to be applied to the symbol. The default is [1.0, 1.0, 1.0].

- If SIZE is specified as a scalar, then the X, Y, and Z scale factors are all equal to the scalar value.
- If SIZE is specified as a 2-element vector, then the X and Y scale factors are as specified by the vector, and the Z scale factor is 1.0.
- If SIZE is specified as a 3-element vector, then the X, Y, and Z scale factors are as specified by the vector.

IDL converts, maintains, and returns this data as double-precision floating-point.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## THICK

A floating-point value between 1.0 and 10.0, specifying the line thickness to used to draw any lines that make up the symbol, in points. The default is 1.0 points.

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

# IDLgrSymbol::Cleanup

The IDLgrSymbol::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrSymbol::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrSymbol::GetProperty

The IDLgrSymbol::GetProperty procedure method retrieves the value of a property or group of properties for the symbol.

## Syntax

*Obj* -> [IDLgrSymbol::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under "IDLgrSymbol Properties" on page 3584 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

## Version History

Introduced: 5.0

# IDLgrSymbol::Init

The IDLgrSymbol::Init function method initializes the plot symbol.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrSymbol' [, *Data*] [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLgrSymbol::]Init([*Data*] [, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### Data

Either an integer value from the list shown below, or an object reference to either an IDLgrModel object or atomic graphic object.

Use one of the following scalar-represented internal default symbols:

- 0 = No symbol
- 1 = Plus sign, '+' (default)
- 2 = Asterisk
- 3 = Period (Dot)
- 4 = Diamond

- 5 = Triangle
- 6 = Square
- 7 = X
- 8 = “Greater-than” Arrow Head (>)
- 9 = “Less-than” Arrow Head (<)

If an instance of the IDLgrModel object class or an atomic graphic object is used, the object tree is used as the symbol. For best results, the object should fill the domain from -1 to +1 in all dimensions. The pre-defined symbols listed above are all defined in the domain -1 to +1.

## Keywords

Any property listed under “IDLgrSymbol Properties” on page 3584 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

Data argument: 5.6

# IDLgrSymbol::SetProperty

The IDLgrSymbol::SetProperty procedure method sets the value of a property or group of properties for the symbol.

## Syntax

*Obj* -> [IDLgrSymbol::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrSymbol Properties” on page 3584 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrTessellator

A tessellator object decomposes a polygon description into a set of triangles. Use the tessellator object to convert complex and/or concave polygons into a form suitable for drawing with the IDLgrPolygon object. IDLgrPolygon can draw only convex polygons correctly.

The polygon contours may intersect each other and may be self-intersecting. The contours may be disjoint, overlapping, or contained within other contours. The contours may also be degenerate, may contain repeated points, and may or may not be closed. The order of the vertices may be either counter-clockwise or clockwise. For best results, the polygon contours should be coplanar.

The tessellator object uses the "odd-winding rule" to determine if a point is in the interior of the polygon and therefore contained in a triangle output by the tessellator. With this rule, a point is in the interior if it is circled an odd number of times as we travel around each of the contours.

**Note**

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

Specify polygon contours with calls to the IDLgrTessellator::AddPolygon method. After adding all the contours, use the IDLgrTessellator::Tessellate method to perform the tessellation and retrieve the resulting list of vertices and connectivity array.

If the polygon contours contain intersecting or self-intersecting contours, the tessellator may return vertices that were not in the original set of vertices specified with the IDLgrTessellator::AddPolygon method. These vertices are created by the intersecting contours.

If your vertex data also includes other information, such as a color for each vertex, then you may wish for this extra information to be created for any new vertices generated by the tessellator. Use the AUXDATA keywords for IDLgrTessellator::AddPolygon and IDLgrTessellator::Tessellate to pass in and retrieve your per-vertex data. The tessellator object interpolates the per-vertex data from neighboring vertices to create new per-vertex data for the new vertices it generates.

In the following example of handling per-vertex data with generated vertices, the polygon is a simple self-intersecting "bow-tie" polygon. It is submitted to the

tessellator with four vertices, but the tessellator returns a fifth at the point of self-intersection. Color data for the four original vertices is also supplied, and the tessellator returns a fifth color.

```
PRO tessaux
    oTess = OBJ_NEW('IDLgrTessellator')
    colors = [[0,255,0],[0,255,0],[0,64,0],[0,64,0]]
    oTess->AddPolygon, [0,1,0,1], [0,0,1,1], AUXDATA=colors
    result = oTess->Tessellate(v, c, AUXDATA=aux)
    PRINT, v[*,4]
    PRINT, aux[*,4]
    oPoly = OBJ_NEW('IDLgrPolygon', v, POLYGONS=c, $
VERT_COLORS=aux, SHADING=1)
    XOBJVIEW, oPoly, /BLOCK
    OBJ_DESTROY, [oTess, oPoly]
END
```

The generated output will be:

```
0.500000     0.500000
  0    159      0
```

## Superclasses

IDLitComponent

## Creation

See “IDLgrTessellator::Init” on page 3598.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- IDLgrTessellator::AddPolygon
- IDLgrTessellator::Cleanup
- IDLgrTessellator::Init
- IDLgrTessellator::Reset
- IDLgrTessellator::Tessellate

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrTessellator Properties

Objects of this class have no properties of their own.

# IDLgrTessellator::AddPolygon

The IDLgrTessellator::AddPolygon procedure method adds a polygon to the tessellator object.

## Syntax

*Obj* -> [IDLgrTessellator::]AddPolygon, *X* [, *Y*[, *Z*]] [, AUXDATA=*array of auxiliary data*] [, /INTERIOR] [, POLYGON=*array of polygon descriptions*]

## Arguments

### X

A 1 x *n*, 2 x *n*, or 3 x *n* array of polygon vertices.

### Y

A vector of Y values. If *X* and *Y* are both specified, they must be one-dimensional vectors of the same length.

### Z

A vector of Z values. If *X*, *Y*, and *Z* are all specified, they must all three be one-dimensional vectors of the same length. If no *Z* values are specified, the *Z* value for the polygon is set to 0.

## Keywords

### AUXDATA

Set this keyword to an array of auxiliary per-vertex data. This array must have dimensions [*m*,*n*] where m is the number of auxiliary data items per vertex and *n* is the number of vertices specified in the *X*, *Y*, and *Z* arguments. If you specify AUXDATA in any invocation of the AddPolygon method, you must specify it on all invocations of the method for the polygons to be tessellated together with the Tessellate method. Further, the value of m in the dimensions must be the same for all polygons. That is, all polygons must have the same number of auxiliary data items for each vertex.

### POLYGON

Set this keyword to an array of polygon descriptions. A polygon description is an integer or long word array of the form: [*n*, $i_0$, $i_1$, ..., $i_{n-1}$], where *n* is the number of vertices that define the polygon, and $i_0..i_{n-1}$ are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices. To ignore an entry in the POLYGON array, set the vertex count, *n*, to 0. To end the drawing list, even if additional array space is available, set *n* to -1. If this keyword is not specified, a single polygon will be generated.

**Note**

The connectivity array described by POLYGONS allows you to add multiple polygons to the tessellator object with a single AddPolygon operation.

### INTERIOR

Set this keyword to set a polygon to be an interior polygon, which is treated as a hole in the exterior polygons.

**Note**

The INTERIOR keyword for the AddPolygon method is no longer needed to inform the tessellator that the polygon defines an exterior or interior boundary. This keyword is ignored by the tessellator because it now performs the interior testing using the odd-winding rule.

## Version History

Introduced: 5.0

AUXDATA keyword: 5.6

# IDLgrTessellator::Cleanup

The IDLgrTessellator::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY,*Obj*

or

*Obj* -> [IDLgrTessellator::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrTessellator::Init

The IDLgrTessellator::Init function method initializes the tessellator object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrTessellator')

or

*Result* = *Obj* -> [IDLgrTessellator::]Init() (*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrTessellator::Reset

The IDLgrTessellator::Reset procedure method resets the object's internal state. All previously added polygons are removed from memory and the object is prepared for a new tessellation task.

## Syntax

*Obj* -> [IDLgrTessellator::]Reset

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrTessellator::Tessellate

The IDLgrTessellator::Tessellate function method performs the actual tessellation.

## Syntax

*Result* = *Obj* -> [IDLgrTessellator::]Tessellate( *Vertices*, *Poly* [, AUXDATA=*variable*] [, /QUIET] )

## Return Value

Returns 1, and the contents of Vertices and Poly are set to the results of the tessellation. Returns 0 if tessellation fails.

## Arguments

If the tessellation succeeds, IDLgrTessellator::Tessellate returns 1 and the contents of Vertices and Poly are set to the results of the tessellation. If the tessellation fails, the function returns 0.

### Vertices

A 2 x *n* array if all the input polygons were 2-D. A 3 x *n* array if all the input polygons were 3-D.

### Poly

An array of polygon descriptions. A polygon description is an integer or long word array of the form: [*n*, $i_0$, $i_1$, ..., $i_{n-1}$], where *n* is the number of vertices that define the polygon, and $i_0$..$i_{n-1}$ are indices into the *X*, *Y*, and *Z* arguments that represent the polygon vertices.

**Note**

On output, the *Vertices* array can be used as the value of the DATA property, and the *Poly* array can be used as the value of the POLYGON property, of an IDLgrPolygon object.

# Keywords

## AUXDATA

Set this keyword to a named variable that receives the auxiliary data associated with each vertex returned in the Vertices argument. The data is an [*m*, *n*] array where m is the number of per-vertex auxiliary data items specified in the call(s) to the AddPolygon method, and n is the number of vertices returned in the Vertices argument. The type of the returned auxiliary data is the same as the type of the data supplied with the AUXDATA keyword in the last call to AddPolygon.

## QUIET

Set this keyword to suppress warning and error message generation due to tessellation errors. !ERROR_STATE is not updated in the case of the return value being ‘0’ when the QUIET keyword is specified.

# Version History

Introduced: 5.0

AUXDATA keywords: 5.6

# IDLgrText

A text object represents one or more text strings that share common rendering attributes. An IDLgrText object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

IDLitComponent

## Creation

See "IDLgrText::Init" on page 3623.

## Properties

Objects of this class have the following properties. See "IDLgrText Properties" on page 3604 for details on individual properties.

- ALIGNMENT
- ALL
- ALPHA_CHANNEL
- BASELINE
- CHAR_DIMENSIONS
- CLIP_PLANES
- COLOR
- ENABLE_FORMATTING
- FONT
- HIDE
- KERNING
- LOCATIONS
- ONGLASS
- ONGLASS
- PALETTE
- PARENT
- RECOMPUTE_DIMENSIONS
- REGISTER_PROPERTIES
- RENDER_METHOD
- STRINGS
- UPDIR
- VERTICAL_ALIGNMENT
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZCOORD_CONV
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrText::Cleanup
- IDLgrText::GetCTM
- IDLgrText::GetProperty
- IDLgrText::Init
- IDLgrText::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrText Properties

IDLgrText objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrText::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrText::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrText::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested horizontal alignment of the text baseline. An alignment of 0.0 (the default) left-justifies the text at the given position; an alignment of 1.0 right-justifies the text, and an alignment of 0.5 centers the text over the given position..

| | | | |
|---|---|---|---|
| **Property Type** | FLOAT | | |
| **Name String** | Horizontal alignment | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ALPHA_CHANNEL

A floating-point value that determines the opacity of the text with respect to the background. Set this property to a value in the range [0.0, 1.0] (1.0 is the default) to draw the text foreground and background with the specified blending factor. A value of 1.0 draws the text opaquely without blending the text with objects already drawn on the destination. Edges of the glyphs are always blended. A value of 0.0 draws no text at all. A value in the middle of the range draws the text semi-transparently, which provides a way of creating labels that are visible while allowing features blocked by the labels to still be seen. This property is used only when the RENDER_METHOD in effect is 0 (Texture).

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Opacity | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## BASELINE

A two- or three-element floating-point vector describing the direction in which the baseline is to be oriented. Use this property in conjunction with the UPDIR property to specify the plane on which the text lies. The default BASELINE is [1.0,0,0] (i.e., parallel to the x-axis).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Baseline direction | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CHAR_DIMENSIONS

A two-element floating-point vector [*width*, *height*] indicating the dimensions (measured in data units) of a bounding box for each character, to be used when scaling text projected in three dimensions. If either *width* or *height* is zero, the text will be scaled such that if it were positioned halfway between the near and far clipping planes, it will appear at the point size associated with this text object's font. The default value is [0, 0]. IDL converts, maintains, and returns this data as double-precision floating-point.

**Note**

If you set the CHAR_DIMENSIONS property to [0,0] (using the SetProperty method), indicating that IDL should calculate the text size, the value (returned by the GetProperty method) will not be updated to reflect the calculated size until you call either the Draw method or the GetTextDimensions method.

For example, if the VIEWPLANE_RECT of the view the text object is being rendered in is set equal to [0,0,10,10] (that is, it spans ten data units in each of the X and Y directions), setting the CHAR_DIMENSIONS property equal to [2, 3] will scale the text such that each character fills 20% of the X range and 30% of the Y range.

This property has no effect if the ONGLASS property is set equal to one..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A$x$ + B$y$ + C$z$ + D = 0. Portions of this object that fall in the half space A$x$ + B$y$ + C$z$ + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects..

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COLOR

The color to be used as the foreground color for the text. The color may be specified as a color lookup table index or as an RGB vector. The default is [0, 0, 0]..

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ENABLE_FORMATTING

A Boolean value that determines whether the text object should honor embedded Hershey-style formatting codes within the strings. (Formatting codes are described in Appendix H, “Fonts”.) The default is not to honor the formatting codes..

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## FILL_BACKGROUND

Set this property to zero (the default) to render the text with a transparent bitmap background, allowing graphics behind the text to show through between the glyphs. Set this property to non-zero to draw the text bitmap background with the color specified by the FILL_COLOR property. This property can only be used when RENDER_METHOD is set to 0 (Texture)..

| | | | |
|---|---|---|---|
| **Property Type** | BOOLEAN | | |
| **Name String** | Fill background | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## FILL_COLOR

An integer vector that determines whether to use a text background color other than the view color. Set this property to -1 (the default) to specify that the text background should be drawn using the view color. Set this property to an RGB color vector or color index value to specify that the text bitmap background should be drawn using the specified color. This property is used only when the FILL_BACKGROUND property has a non-zero value and the RENDER_METHOD in effect is 0 (Texture).

In a property sheet, this property appears as a color property

| | | | |
|---|---|---|---|
| **Property Type** | COLOR | | |
| **Name String** | Fill background | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## FONT

An object reference to an instance of an IDLgrFont object class to describe the font to use to draw this string. The default is 12 point Helvetica. See IDLgrFont for details.

**Note**

If the default font is in use, retrieving the value of the FONT property (using the GetProperty method) will return a null object..

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic..

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## KERNING

A Boolean value that determines whether to enable kerning while rendering characters. Kerning reduces the amount of space between glyphs if the shape of each glyph allows it, according to the font information stored in the font's file (e.g., AV). Set this property to a non-zero value (the default is zero) to enable kerning. Enabling kerning may not necessarily result in rendering glyphs more closely together because some fonts do not contain the required kerning information. This property is used only when the RENDER_METHOD in effect is 0 (Texture)..

| | | | |
|---|---|---|---|
| **Property Type** | BOOLEAN | | |
| **Name String** | Kerning | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LOCATIONS

A floating-point array of one or more two- or three-element vectors specifying the coordinates (measured in data units) used to position the string(s). The default location for each string is [0,0,0]. Each vector is of the form [*x*, *y*] or [*x*, *y*, *z*]; if *z* is not provided, it is assumed to be zero. Each location corresponds to a string in the *String* argument; the number of locations should be equal the number of strings. IDL converts, maintains, and returns this data as double-precision floating-point..

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Text locations | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ONGLASS

A Boolean value that indicates whether the text should be displayed “on the glass”. The default is projected 3-D text..

| | | | |
|---|---|---|---|
| **Property Type** | BOOLEAN | | |
| **Name String** | On glass | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp)..

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object..

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## RECOMPUTE_DIMENSIONS

An integer value that indicates when this text object's character dimensions (refer to the CHAR_DIMENSIONS property) are to be recomputed automatically:

- 0 = The physical size of the text is affected by model and view transforms. The size of the text in terms of data units is obtained from CHAR_DIMENSIONS. Since the character dimensions are specified in data units, the text will maintain the data space size specified by CHAR_DIMENSIONS as the transforms change. In other words, the physical text size changes along with other primitives. If the value of this property is [0, 0], the text font's point size is used to compute the physical size of the text in terms of data units using the transforms in effect for the first draw. This setting is the default value for this property.
- 1 = The physical size of the text is only affected by model transforms. The CHAR_DIMENSIONS property is ignored. The size of the text is computed from the font's point size the first time it is drawn, and IDL does not try to keep the size of the text constant with respect to changes in the model transforms.
- 2 = The physical size of the text is held constant, even as the model and view change. The CHAR_DIMENSIONS property is ignored and the text is always drawn with a physical size equal to the text font's point size. IDL adjusts its internal text transforms to maintain the physical size of the text.

In a property sheet, this property appears as an enumerated list with the following options:

- Never
- Previous

- Always

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Recompute dimensions | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RENDER_METHOD

A Boolean value that determines how the text object will be rendered. Set this property to one of the following values:

- 0 = TEXTURE. IDL renders the text by placing a bitmap representation of a glyph into a texture map and then rendering a polygon with the texture map. The FILL_BACKGROUND, ALPHA_CHANNEL, and FILL_COLOR properties control the drawing of the background portions of the texture map and how the entire texture map is blended into the scene. Leaving these three properties set to their default values produces a result that closely approximates the TRIANGLES rendering method. One important difference is that the glyph bitmaps are generated by the FreeType font rendering library, producing glyphs that are more accurately rendered and anti-aliased than those drawn with the TRIANGLES method. The TEXTURE method cannot be used on indexed color destinations. The text is rendered with the TRIANGLES method if the destination color model is indexed.
- 1 = TRIANGLES. IDL renders the text by tessellating the glyph outline into a set of small triangles that are then drawn to produce the solid glyph. IDL also draws a blended line around the edge of the glyph to approximate anti-aliasing. This setting forces IDL to use the process it used as the default before IDL 6.0.

In a property sheet, this property appears as an enumerated list with the following options:

- Texture
- Triangles

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Render method | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## STRINGS

The string (or vector of strings) associated with the text object. This property is the same as the *String* argument described above.

If the number of strings matches the number of locations (as specified by the LOCATIONS property), the existing locations are used.

**Note**

If the number of strings *does not* match the number of locations, the number of locations is modified to match the number of strings, and the location value for each string is reset to [0,0,0]..

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Text strings | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## UPDIR

A two- (or three-) element floating-point vector describing the vertical direction for the string. The *upward direction* is the direction defined by a vector pointing from the origin to the point specified. Use this property in conjunction with the BASELINE property to specify the plane on which the text lies; the direction specified by UPDIR should be orthogonal to the direction specified by BASELINE. The default UPDIR is [0.0, 1.0, 0.0] (i.e., parallel to the *Y* axis).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Up direction | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## VERTICAL_ALIGNMENT

A floating-point value between 0.0 and 1.0 to indicate the requested vertical alignment of the text. An alignment of 0.0 (the default) bottom-justifies the text at the given location; an alignment of 1.0 top-justifies the text at the given location..

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Vertical alignment | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZCOORD_CONV

A floating-point vector, [$s_0$, $s_1$], of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{NormalizedZ} = s_0 + s_1 * \text{DataZ}$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZRANGE

A two-element floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object. IDL maintains and returns this property in double-precision floating-point.

**Note**

Until the text is drawn to the destination object, the [XYZ]RANGE properties will only report the locations of the text. Use the GetTextDimensions method of the destination object to get the data dimensions of the text prior to a draw operation..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrText::Cleanup

The IDLgrText::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrText::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrText::GetCTM

The IDLgrText::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrText::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*] )

## Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the text object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrText::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrText::GetProperty

The IDLgrText::GetProperty procedure method retrieves the value of a property or group of properties for the text.

## Syntax

*Obj* -> [IDLgrText::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrText Properties” on page 3604 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrText::Init

The IDLgrText::Init function method initializes the text object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrText' [, *String or vector of strings*] [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLgrText::]Init([*String or vector of strings*] [, *PROPERTY=value*]) (*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### String

The string (or vector of strings) to be created. If this argument is not a string, it is converted prior to creation of the text object using the default formatting rules.

**Note**

Strings have a default location of [0,0,0]. Use the LOCATIONS property to provide a different location for each string.

## Keywords

Any property listed under “IDLgrText Properties” on page 3604 that contains the word “Yes” in the “Init” column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

# IDLgrText::SetProperty

The IDLgrText::SetProperty procedure method sets the value of a property or group of properties for the text.

## Syntax

*Obj* -> [IDLgrText::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrText Properties” on page 3604 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrView

A view object represents a rectangular area in which graphics objects are drawn. It is a container for objects of the IDLgrModel class.

## Superclasses

IDL_Container

IDLitComponent

TrackBall

## Creation

See "IDLgrView::Init" on page 3640.

## Properties

Objects of this class have the following properties. See "IDLgrView Properties" on page 3628 for details on individual properties.

- ALL
- COLOR
- DEPTH_CUE
- DIMENSIONS
- DOUBLE
- EYE
- HIDE
- LOCATION
- PARENT
- PROJECTION
- REGISTER_PROPERTIES
- TRANSPARENT
- UNITS
- VIEWPLANE_RECT

- ZCLIP

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrView::Add
- IDLgrView::Cleanup
- IDLgrView::GetByName
- IDLgrView::GetProperty
- IDLgrView::Init
- IDLgrView::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrView Properties

IDLgrView objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrView::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrView::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrView::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## COLOR

The color for the view. This is the color to which the view area will be erased before its contents are drawn. The color may be specified as a color lookup table index or as an RGB vector. The default is [255, 255, 255] (white)..

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_CUE

A two-element floating-point array [*zbright*, *zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color. Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between $Z_{bright}$ and $Z_{dim}$ determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0]..

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Depth cue | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the dimensions of the viewport (the rectangle in which models are displayed on a graphics destination). By default, the viewport dimensions are set to [0, 0], which indicates that it will match the dimensions of the graphics destination to which it is drawn. The dimensions are measured in the units specified by the UNITS property..

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DOUBLE

A Boolean value that controls the precision used for rendering the entire contents of the view. If set, IDL calculates the transformations used for the modeling and view transforms using double-precision floating-point arithmetic. This allows the values specified for the VIEWPLANE_RECT, modeling transforms in IDLgrModel objects, and coordinate data in atomic graphic objects to be used as double-precision before mapping to device coordinates.

**Note**

If this property is set to 0, IDL uses single-precision floating-point arithmetic for these values, which can cause loss of significance and incorrect rendering of data. Setting this property to 1 may impact graphics performance and should only be used when handling data requiring double precision..

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Double precision | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## EYE

A floating-point value that specifies the distance from the eyepoint to the viewplane (Z=0). The default is 4.0. The eyepoint is always centered within the viewplane rectangle. (That is, if the VIEWPLANE_RECT property is set equal to [0,0,1,1], the eyepoint will be at X=0.5, Y=0.5.) IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Eye distance | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LOCATION

A two-element floating-point vector of the form [*x*, *y*] specifying the position of the lower left corner of the view. The default is [0, 0], measured in device units.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Viewport location | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object..

| **Property Type** | Object reference | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** | **Init:** | **Registered:** No |

## PROJECTION

An integer value indicating the type of projection to use within this view. All models displayed within this view will be projected using this type of projection. Valid values are described below.

- 1 = Orthogonal projection (default).
- 2 = Perspective: Indicates that all models are projected toward the eye (located at the origin), which is the apex of the viewing frustum. With a perspective projection, models that are farther away from the eye will appear smaller in the view than models that are nearer to the eye..

In a property sheet, this property appears as an enumerated list with the following options:

- None
- Orthogonal
- Perspective

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Projection | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## TRANSPARENT

A Boolean value that determines whether to disable the viewport erase, making the viewport transparent..

| | | | |
|---|---|---|---|
| **Property Type** | BOOLEAN | | |
| **Name String** | Transparent | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## UNITS

An integer value that specifies the units of measure for this view. Valid values are:

- 0 = Device (default)
- 1 = Inches

- 2 = Centimeters
- 3 = Normalized: relative to the graphics destination's *rect*.

**Note**

If you set the UNITS property (using the SetProperty method) of a view without also setting the LOCATION and DIMENSIONS properties, IDL will use the existing size and location values in the new units, *without conversion*. This means that if your view's location and dimensions were previously measured in centimeters, and you change the value of UNITS to 1 (measurement in inches), the actual size of the view object will change..

In a property sheet, this property appears as an enumerated list with the following options:

- Device
- Inches
- Centimeters
- Normalization

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Units | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## VIEWPLANE_RECT

A four-element floating-point vector of the form [*x, y, width, height*] to describe the bounds in x and y of the view volume. Objects within the view volume are projected into the viewport. These values are measured in normalized space. The default is [-1.0, -1.0, 2.0, 2.0] IDL converts, maintains, and returns this data as double-precision floating-point.

**Note**

The z bounds of the view volume are set via the ZCLIP property. The viewplane rectangle is always located at Z=0.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Viewplane rectangle | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ZCLIP

A two element floating-point vector representing the near and far clipping planes to be applied to the objects in this view. The vector should take the form [*near*, *far*]. By default, these values are [1, -1]. IDL converts, maintains, and returns this data as double-precision floating-point.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Z clipping | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

# IDLgrView::Add

The IDLgrView::Add procedure method adds a child to this view.

## Syntax

*Obj* -> [IDLgrView::]Add, *Model* [, POSITION=*index*]

## Arguments

### Model

An instance of the IDLgrModel object class.

## Keywords

### POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

## Version History

Introduced 5.0

# IDLgrView::Cleanup

The IDLgrView::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrView::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced 5.0

# IDLgrView::GetByName

The IDLgrView::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

**Note**

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

## Syntax

*Result* = *Obj* -> [IDLgrView::]GetByName(*Name*)

## Return Value

Returns contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

## Arguments

### Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of object3 would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

## Keywords

None

## Version History

Introduced 5.0

# IDLgrView::GetProperty

The IDLgrView::GetProperty procedure method retrieves the value of the property or group of properties for the view.

## Syntax

*Obj* -> [IDLgrView::]GetProperty[, *PROPERTY=variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrView Properties” on page 3628 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced 5.0

# IDLgrView::Init

The IDLgrView::Init function method initializes the view object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrView' [, *PROPERTY=value*])

or

*Result* = *Obj* -> [IDLgrView::]Init([*PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrView Properties" on page 3628 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced 5.0

# IDLgrView::SetProperty

The IDLgrView::SetProperty procedure method sets the value of the property or group of properties for the view.

## Syntax

*Obj* -> [IDLgrView::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrView Properties” on page 3628 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced 5.0

# IDLgrViewgroup

The IDLgrViewgroup object is a simple container object, very similar to the IDLgrScene object. It contains one or more IDLgrView objects and an IDLgrScene can contain one or more of these objects. This object is special in that it can also contain objects which do not have a Draw method (e.g. IDLgrPattern and IDLgrFont). An IDLgrViewgroup object cannot be returned by a call to the IDLgrWindow::Select method.

## Superclasses

IDL_Container

IDLitComponent

## Creation

See "IDLgrViewgroup::Init" on page 3652.

## Properties

Objects of this class have the following properties. See "IDLgrViewgroup Properties" on page 3645 for details on individual properties.

- ALL
- HIDE
- PARENT
- REGISTER_PROPERTIES

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrViewgroup::Add
- IDLgrViewgroup::Cleanup
- IDLgrViewgroup::GetByName
- IDLgrViewgroup::GetProperty

- IDLgrViewgroup::Init
- IDLgrViewgroup::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.1

# IDLgrViewgroup Properties

IDLgrViewgroup objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrViewgroup::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrViewgroup::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrViewgroup::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## HIDE

A Boolean value to indicate whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)
- False = Do not draw graphic..

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this viewgroup.

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLgrViewgroup::Add

The IDLgrViewgroup::Add function method verifies that the added item is not an instance of the IDLgrScene or IDLgrViewgroup object. If it is not, IDLgrViewgroup:Add adds the object to the specified viewgroup.

## Syntax

*Obj* -> [IDLgrViewgroup::]Add, *Object* [, POSITION=*index*]

## Arguments

### Object

An instance of an object or a list of objects. Objects which subclass IDLgrScene or IDLgrViewgroup can not be added (avoiding circularity constraints). All other objects are allowed.

## Keywords

### POSITION

Set this keyword equal to the zero-based index of the position within the container at which the new object should be placed.

## Version History

Introduced: 5.1

# IDLgrViewgroup::Cleanup

The IDLgrViewgroup::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY,*Obj*

or

*Obj* -> [IDLgrViewgroup::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrViewgroup::GetByName

The IDLgrViewgroup::GetByName function method finds contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

**Note**

The GetByName function does *not* perform a recursive search through the object hierarchy. If a fully qualified object name is not specified, only the contents of the current container object are inspected for the named object.

## Syntax

*Result* = *Obj* -> [IDLgrViewgroup::]GetByName(*Name*)

## Return Value

Returns contained objects by name. If the named object is not found, the GetByName function returns a null object reference.

## Arguments

### Name

A string containing the name of the object to be returned.

Object naming syntax is very much like the syntax of a UNIX filesystem. Objects contained by other objects can include the name of their parent object; this allows you to create a fully qualified name specification. For example, if `object1` contains `object2`, which in turn contains `object3`, the string specifying the fully qualified object name of object3 would be `'object1/object2/object3'`.

Object names are specified relative to the object on which the GetByName method is called. If used at the beginning of the name string, the `/` character represents the top of an object hierarchy. The string `'..'` represents the object one level “up” in the hierarchy.

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrViewgroup::GetProperty

The IDLgrViewgroup::GetProperty procedure method retrieves the value of a property or group of properties for the viewgroup object.

## Syntax

*Obj* -> [IDLgrViewgroup::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under "IDLgrViewgroup Properties" on page 3645 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

## Version History

Introduced: 5.1

# IDLgrViewgroup::Init

The IDLgrViewgroup::Init function method initializes the viewgroup object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrViewgroup' [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrViewgroup::]Init([, *PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrViewgroup Properties" on page 3645 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.1

# IDLgrViewgroup::SetProperty

The IDLgrViewgroup::SetProperty procedure method sets the value of a property or group of properties for the viewgroup.

## Syntax

*Obj* -> [IDLgrViewgroup::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrViewgroup Properties” on page 3645 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.1

# IDLgrVolume

A volume object represents a mapping from a three-dimensional array of data to a three-dimensional array of voxel colors, which, when drawn, are projected to two dimensions.

An IDLgrVolume object is an *atomic graphic object*; it is one of the basic drawable elements of the IDL Object Graphics system, and it is not a container for other objects.

## Superclasses

IDLitComponent

## Creation

See "IDLgrVolume::Init" on page 3679.

## Properties

Objects of this class have the following properties. See "IDLgrVolume Properties" on page 3657 for details on individual properties.

- ALL
- AMBIENT
- BOUNDS
- CLIP_PLANES
- COMPOSITE_FUNCTION
- CUTTING_PLANES
- DATA0
- DATA1
- DATA2
- DATA3
- DEPTH_CUE
- DEPTH_TEST_DISABLE
- DEPTH_TEST_FUNCTION
- DEPTH_WRITE_DISABLE
- HIDE
- HINTS
- INTERPOLATE
- LIGHTING_MODEL
- NO_COPY
- OPACITY_TABLE0
- OPACITY_TABLE1
- PALETTE
- PARENT
- REGISTER_PROPERTIES

- RENDER_STEP
- RGB_TABLE0
- RGB_TABLE1
- TWO_SIDED
- VALID_DATA
- VOLUME_SELECT
- XCOORD_CONV
- XRANGE
- YCOORD_CONV
- YRANGE
- ZBUFFER
- ZCOORD_CONV
- ZERO_OPACITY_SKIP
- ZRANGE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrVolume::Cleanup
- IDLgrVolume::ComputeBounds
- IDLgrVolume::GetCTM
- IDLgrVolume::GetProperty
- IDLgrVolume::Init
- IDLgrVolume::PickVoxel
- IDLgrVolume::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrVolume Properties

IDLgrVolume objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrVolume::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrVolume::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrVolume::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## AMBIENT

The color and intensity of the volume’s base ambient lighting. Color is specified as an RGB vector. The default is [255, 255, 255]. AMBIENT is applicable only when LIGHTING_MODEL is set..

In a property sheet, this property appears as a color property.

| **Property Type** | COLOR | | |
|---|---|---|---|
| **Name String** | Ambient color | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## BOUNDS

A six-element floating-point vector of the form [$x_{min}$, $y_{min}$, $z_{min}$, $x_{max}$, $y_{max}$, $z_{max}$], which represents the sub-volume to be rendered. .

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Subvolume bounds | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CLIP_PLANES

A 4-by-*N* floating-point array that specifies the coefficients of the clipping planes to be applied to this object. The four coefficients for each clipping plane are of the form [A, B, C, D], where A*x* + B*y* + C*z* + D = 0. Portions of this object that fall in the half space A*x* + B*y* + C*z* + D > 0 will be clipped. By default, the value of this property is a scalar (-1) indicating that no clipping planes are to be applied.

**Note**

The clipping planes specified via this property are applied in addition to the near and far clipping planes associated with the IDLgrView in which this object appears.

**Note**

Clipping planes are applied in the data space of this object (prior to the application of any *x*, *y*, or *z* coordinate conversion).

**Note**

To determine the maximum number of clipping planes supported by the device, use the MAX_NUM_CLIP_PLANES property of the GetDeviceInfo method for the IDLgrBuffer, IDLgrClipboard, IDLgrWindow, and IDLgrVRML objects.

**Note**

Clipping planes are equivalent to cutting planes (refer to the CUTTING_PLANES property). The CUTTING_PLANES will be applied first, then the CLIP_PLANES (until a maximum number of planes is reached)..

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## COMPOSITE_FUNCTION

An integer value that determines the composite function to be used to measure the value of a pixel on the viewing plane by analyzing the voxels falling along the corresponding ray. Specify one of the following compositing functions:

- 0 = Alpha (default): Alpha-blending. The recursive equation

  ```
  dest' = src * srcalpha + dest * (1 - srcalpha)
  ```

  is used to compute the final pixel color.
- 1 = MIP: Maximum intensity projection. The value of each pixel on the viewing plane is set to the brightest voxel, as determined by its opacity. The most opaque voxel's color appropriation is then reflected by the pixel on the viewing plane.
- 2 = Alpha sum: Alpha-blending. The recursive equation

  ```
  dest' = src + dest * ( 1 - srcalpha)
  ```

  is used to compute the final pixel color. This equation assumes that the color tables have been pre-multiplied by the opacity tables. The accumulated values can be no greater than 255.
- 3 = Average: Average-intensity projection. The resulting image is the average of all voxels along the corresponding ray. Disables lighting and only works with grey scale palettes. Will not work with four-channel volumes..

In a property sheet, this property appears as an enumerated list with the following options:

- Alpha blending
- Maximum intensity projection
- Alpha sum

- Average intensity

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Composite function | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## CUTTING_PLANES

A floating-point array with dimensions (4, *n*) specifying the coefficients of *n* cutting planes. The cutting plane coefficients are in the form {{$n_x$, $n_y$, $n_z$, $D$}, ...} where $(n_x)X+(n_y)Y+(n_z)Z+ D > 0$, and (*X, Y, Z*) are the voxel coordinates. To clear the cutting planes, set this property to any scalar value (e.g. CUTTING_PLANES = 0). By default, no cutting planes are defined.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Cutting planes | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DATA0

A three-element array of any type of the format ($d_x$, $d_y$, $d_z$), which specifies a data volume. Setting this property is the same as including the $vol_0$ argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA1, DATA2, or DATA3, all existing data is removed from the object..

| **Property Type** | Array of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DATA1

A three-element array of any type of the format ($d_x$, $d_y$, $d_z$), which specifies a data volume. Setting this property is the same as including the $vol_1$ argument at creation

time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA2, or DATA3, all existing data is removed from the object..

| **Property Type** | Array of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DATA2

A three-element array of any type of the format ($d_x$, $d_y$, $d_z$), which specifies a data volume. Setting this property is the same as including the $vol_2$ argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA3, all existing data is removed from the object..

| **Property Type** | Array of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DATA3

A three-element array of any type of the format ($d_x$, $d_y$, $d_z$), which specifies a data volume. Setting this property is the same as including the $vol_3$ argument at creation time. If the data volume dimensions do not match those of any pre-existing data in DATA0, DATA1, or DATA2, all existing data is removed from the object.

**Note**

DATA0, DATA1, DATA2, and DATA3 sizes are dynamic..

| **Property Type** | Array of any type | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## DEPTH_CUE

A two-element floating-point array [*zbright, zdim*] specifying the near and far Z planes between which depth cueing is in effect. Depth cueing is only honored when drawing to a destination object that uses the RGB color model.

Depth cueing causes an object to appear to fade into the background color of the view object with changes in depth. If the depth of an object is further than *zdim* (that is, if the object's location in the Z direction is farther from the origin than the value specified by *zdim*), the object will be painted in the background color.

Similarly, if the object is closer than the value of *zbright*, the object will appear in its "normal" color. Anywhere in-between, the object will be a blend of the background color and the object color. For example, if the DEPTH_CUE property is set to [-1,1], an object at the depth of 0.0 will appear as a 50% blend of the object color and the view color.

The relationship between $Z_{bright}$ and $Z_{dim}$ determines the result of the rendering:

- $Z_{bright} < Z_{dim}$: Rendering darkens with depth.
- $Z_{bright} > Z_{dim}$: Rendering brightens with depth.
- $Z_{bright} = Z_{dim}$: Disables depth cueing.

You can disable depth cueing by setting $z_{bright} = z_{dim}$. The default is [0.0, 0.0]..

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Depth cue range | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_DISABLE

An integer value that determines whether depth testing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth testing. A model may also enable or disable depth testing.
- Set this property to 1 to explicitly disable depth buffer testing while drawing this object.
- Set this property to 2 to explicitly enable depth testing for this object.

Disabling depth testing allows an object to draw itself on top of other objects already on the screen, even if the object is located behind them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_TEST_FUNCTION

An integer value that determines the depth test function. Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always sets a depth test function of LESS. A model may also set a depth test function value. The graphics device compares the object's depth at a particular pixel location with the depth stored in the depth buffer at that same pixel location. If the comparison test passes, the object's pixel is drawn at that location on the screen and the depth buffer is updated (if depth writing is enabled).

Set this property to any of the following values to use the desired function while rendering this object.

- 0 = INHERIT - use value from parent model or view.
- 1 = NEVER - never passes.
- 2 = LESS - passes if the object's depth is less than the depth buffer's value.
- 3 = EQUAL - passes if the object's depth is equal to the depth buffer's value.
- 4 = LESS OR EQUAL - passes if the object's depth is less than or equal to the depth buffer's value.
- 5 = GREATER - passes if the object's depth is greater than or equal to the depth buffer's value.
- 6 = NOT EQUAL - passes if the object's depth is not equal to the depth buffer's value.
- 7 = GREATER OR EQUAL - passes if the object's depth is greater than or equal to the depth buffer's value.
- 8 = ALWAYS - always passes

Less means closer to the viewer.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Test Enable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DEPTH_WRITE_DISABLE

An integer value that determines whether depth writing is disabled.

- Set this property to 0 (the default) to inherit the value set by the parent model or view. The parent view always enables depth writing. A model may also enable or disable depth writing.
- Set this property to 1 to explicitly disable depth buffer writing while rendering this object.
- Set this property to 2 to explicitly enable depth writing for this object.

Disabling depth writing allows an object to be overdrawn by other objects, even if the object is located in front of them.

This property is registered as an enumerated list, but it is hidden by default.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Depth Write Disable | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HIDE

A Boolean value indicating whether this object should be drawn:

- 0 = Draw graphic (the default)
- 1 = Do not draw graphic

In a property sheet, this property appears as an enumerated list with the following options:

- True = Draw graphic (the default)

- False = Do not draw graphic..

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Show | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## HINTS

An integer value that specifies one of the following acceleration hints:

- 0 = Disables all acceleration hints (default).
- 1 = Enables Euclidean distance map (EDM) acceleration. This option generates a volume map containing the distance from any voxel to the nearest non-zero opacity voxel. The map is used to speed ray casting by allowing the ray to jump over open spaces. It is most useful with sparse volumes. After setting the EDM hint, the draw operation generates the volume map; this process can take some time. Subsequent draw operations will reuse the generated map and may be much faster, depending on the volume's sparseness. A new map is not automatically generated to match changes in opacity tables or volume data (for performance reasons). The user may force recomputation of the EDM map by setting the HINTS property to 1 again.
- 2 = Enables the use of multiple CPUs for volume rendering if the platforms used support such use. If HINTS is set to 2, IDL will use all the available (up to 8) CPUs to render portions of the volume in parallel.
- 3 = Selects the two acceleration options described above..

In a property sheet, this property appears as an enumerated list with the following options:

- Disable
- Euclidean distance map (EDM)
- Multiple CPU
- EDM and Multiple CPU

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Acceleration hints | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## INTERPOLATE

A Boolean value that determines whether to use Trilinear interpolation to determine the data value for each step on a ray. Setting this property improves the quality of images produced, at the cost of more computing time, especially when the volume has low resolution with respect to the size of the viewing plane. Nearest neighbor sampling is used by default..

In a property sheet, this property appears as an enumerated list with the following options:

- Nearest neighbor
- Trilinear

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Interpolation | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## LIGHTING_MODEL

A Boolean value that determines whether to use the current lighting model during rendering in conjunction with a local gradient evaluation.

**Note**

Only DIRECTIONAL light sources are honored by the volume object. Because normals must be computed for all voxels in a lighted view, enabling light sources increases the rendering time..

| | | | |
|---|---|---|---|
| **Property Type** | BOOLEAN | | |
| **Name String** | Use lighting | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## NO_COPY

A Boolean value that determines whether to relocate volume data from the input variables to the volume object, leaving the input variables undefined. Only the

DATA0 property and the *vol0* argument are affected. If this property is omitted, the input volume data will be duplicated and a copy will be stored in the object..

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## OPACITY_TABLE0

A 256-element byte array that specifies the opacity table for DATA0. The default table is the linear ramp..

| | | | |
|---|---|---|---|
| **Property Type** | Byte array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## OPACITY_TABLE1

A 256-element byte array that specifies the opacity table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1..

| | | | |
|---|---|---|---|
| **Property Type** | Byte array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that defines the color palette of this object. This property is only used if the destination device is using the RGB color model. If so, and a color value for the object is specified as a color index value, the palette set by this property is used to translate the color to RGB space. If the PALETTE property on this object is not set, the destination object PALETTE property is used (which defaults to a grayscale ramp)..

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## PARENT

An object reference to the object that contains this object..

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RENDER_STEP

A three-element floating-point vector of the form [*x*, *y*, *z*] that specifies the stepping factor through the voxel matrix..

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | XYZ render step | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## RGB_TABLE0

A 256 x 3-element byte array that specifies the RGB color table for DATA0. The default table is the linear ramp. .

| | | | |
|---|---|---|---|
| **Property Type** | Byte array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## RGB_TABLE1

A 256 x 3-element byte array that specifies the RGB color table for DATA1. The default table is the linear ramp. This table is used only when VOLUME_SELECT is set equal to 1..

| | | | |
|---|---|---|---|
| **Property Type** | Byte array | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## TWO_SIDED

A Boolean value that determines whether the lighting model uses a two-sided voxel gradient. The two-sided gradient is different from the one-sided gradient (default) in that the absolute value of the inner product of the light direction and the surface gradient is used instead of clamping to 0.0 for negative values. .

In a property sheet, this property appears as an enumerated list with the following options:

- One-sided
- Two-sided

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Voxel gradient | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## VALID_DATA

An integer array (one per volume, DATA0, DATA1, etc.) which have the value 1 if volume data has been loaded for that volume and 0 if that volume data is currently undefined..

| **Property Type** | Integer array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## VOLUME_SELECT

An integer value that selects the form of the volume to be rendered. The VOLUME_SELECT property is used to modify the `src` and `srcalpha` parameters for the COMPOSITE_FUNCTION property.

- 0 = render voxels from the 8bit DATA0 volume (the default)

```
src = RGB_TABLE0[DATA0]
srcalpha = OPACITY_TABLE0[DATA0]
```

- 1 = render voxels formed by modulating the RGBA components from DATA0 and DATA1 (after RGB and OPACITY table lookups).

```
src = (RGB_TABLE0[DATA0]*RGB_TABLE1[DATA1])/256
srcalpha=(OPACITY_TABLE0[DATA0]*OPACITY_TABLE1[DATA1])/256
```

- 2 = render voxels formed using a byte from DATA0 (red), DATA1 (green), DATA2(blue) and DATA3(alpha). The keywords OPACITY_TABLE0 and RGB_TABLE0, described above, are used to indirect the data from each volume before forming the RGBA pixel.

```
src=(RGB_TABLE[DATA0,0],RGB_TABLE[DATA1,1],RGB_TABLE[DATA2,2])/256
srcalpha = (OPACITY_TABLE0[DATA3])/256.
```

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert X coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}X = s_0 + s_1 * \text{Data}X$$

Recommended values are:

$$[(-X_{min})/(X_{max}-X_{min}),\ 1/(X_{max}-X_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## XRANGE

A two-element double-precision floating-point vector of the form [*xmin*, *xmax*] that specifies the range of *x* data coordinates covered by the graphic object..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## YCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Y coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Y = s_0 + s_1 * \text{Data}Y$$

Recommended values are:

$$[(-Y_{min})/(Y_{max}-Y_{min}),\ 1/(Y_{max}-Y_{min})]$$

The default is [0.0, 1.0]. IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## YRANGE

A two-element double-precision floating-point vector of the form [*ymin*, *ymax*] that specifies the range of *y* data coordinates covered by the graphic object..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## ZBUFFER

A Boolean value that determines whether to clip the rendering to the current Z-buffer and then update the buffer. The default is to not modify the current Z-buffer..

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Update Z buffer | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ZCOORD_CONV

A floating-point vector, $[s_0, s_1]$, of scaling factors used to convert Z coordinates from data units to normalized units. The formula for the conversion is as follows:

$$\text{Normalized}Z = s_0 + s_1 * \text{Data}Z$$

Recommended values are:

$$[(-Z_{min})/(Z_{max}-Z_{min}),\ 1/(Z_{max}-Z_{min})]$$

The default is [0.0, 1.0]IDL converts, maintains, and returns this data as double-precision floating-point..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## ZERO_OPACITY_SKIP

A Boolean value that determines whether to skip voxels with an opacity of 0. This property can increase the output contrast of MIP (MAXIMUM_INTENSITY) projections by allowing the background to show through. If this property is set,

voxels with an opacity of zero will not modify the Z-buffer. The default (not setting the property) continues to render voxels with an opacity of zero..

| **Property Type** | BOOLEAN | | |
|---|---|---|---|
| **Name String** | Skip zero opacity | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ZRANGE

A two-element double-precision floating-point vector of the form [*zmin*, *zmax*] that specifies the range of *z* data coordinates covered by the graphic object..

| **Property Type** | Floating-point vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## Obsolete Properties

The following properties are obsolete:

- CUTTING_PLANES

# IDLgrVolume::Cleanup

The IDLgrVolume::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrVolume::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrVolume::ComputeBounds

The IDLgrVolume::ComputeBounds procedure method computes the smallest bounding box that contains all voxels whose opacity lookup is greater than a given opacity value. The BOUNDS property is updated to the computed bounding box.

## Syntax

*Obj* -> [IDLgrVolume::]ComputeBounds [, OPACITY=*value*] [, /RESET] [, VOLUMES=*int array*]

## Arguments

None

## Keywords

### OPACITY

Set this keyword to the opacity value to be used to determine which voxels are included within the bounding box. All voxels whose opacity lookup is greater than this value will be included. The default value is zero.

### RESET

Set this keyword to cause the BOUNDS keyword of IDLgrVolume::Init to be reset to contain the entire volume.

### VOLUMES

Set this keyword to an array of integers which select which volumes to consider when computing the bounding box. A non-zero value selects a volume to be searched. The default is to search all loaded volumes. For example: VOLUMES=[0,1] will cause ComputeBounds to search only the volume loaded in DATA1.

## Version History

Introduced: 5.0

# IDLgrVolume::GetCTM

The IDLgrVolume::GetCTM function method returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Syntax

*Result* = *Obj* -> [IDLgrVolume::]GetCTM( [, DESTINATION=*objref*] [, PATH=*objref(s)*] [, TOP=*objref to IDLgrModel object*] )

## Return Value

Returns the 4-by-4 double-precision floating-point graphics transform matrix from the current object upward through the graphics tree.

## Arguments

None

## Keywords

### DESTINATION

Set this keyword to the object reference of a destination object to specify that the projection matrix for the View object in the current tree be included in the returned transformation matrix. The resulting matrix will transform a point in the data space of the object on which the GetCTM method is called into a normalized coordinate system (-1 to +1 in X, Y, and Z), relative to the View object that contains the volume object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the transformation matrix. Each path object reference specified with this keyword must contain an alias. The transformation matrix is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVolume::GetCTM is called from within a Draw method, with the DESTINATION keyword set and the PATH keyword not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

### TOP

Set this keyword equal to the object reference to an IDLgrModel object to specify that the returned matrix accumulate from the object on which the GetCTM method is called up to but not including the specified model object.

## Version History

Introduced: 5.0

# IDLgrVolume::GetProperty

The IDLgrVolume::GetProperty procedure method retrieves the value of a property or group of properties for the volume.

## Syntax

*Obj* -> [IDLgrVolume::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under “IDLgrVolume Properties” on page 3657 that contains the word “Yes” in the “Get” column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object’s superclass.

## Version History

Introduced: 5.0

# IDLgrVolume::Init

The IDLgrVolume::Init function method initializes the volume object. At least one volume must be specified, via arguments or keywords.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrVolume' [, *vol0* [, *vol1* [, *vol2* [, *vol3*]]]]
[, *PROPERTY=value*])

or

*Result = Obj ->* [IDLgrVolume::]Init([*vol0* [, *vol1* [, *vol2* [, *vol3*]]]]
[, *PROPERTY=value*]) (*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

### $vol_0$

A three-dimensional array ($d_x$, $d_y$, $d_z$) which specifies a data volume.

### $vol_1$

A three-dimensional array ($d_x$, $d_y$, $d_z$) which specifies a data volume.

### $vol_2$

A three-dimensional array ($d_x$, $d_y$, $d_z$) which specifies a data volume.

### $vol_3$

A three-dimensional array ($d_x$, $d_y$, $d_z$) which specifies a data volume.

**Note**

If two or more of the above arguments are specified, they must have matching dimensions.

## Keywords

Any property listed under "IDLgrVolume Properties" on page 3657 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

CLIP_PLANES keyword: 5.6

# IDLgrVolume::PickVoxel

The IDLgrVolume::PickVoxel function method computes the coordinates of the voxel projected to a location specified by the 2-D device coordinates point, [$x_i$, $y_i$], and the current Z-buffer. The function returns the volume indices as a a vector of three long integers. If the selected point is not within the volume, this function returns [-1,-1,-1].

## Syntax

*Result* = *Obj* -> [IDLgrVolume::]PickVoxel ( *Win*, *View*, *Point* [, PATH=*objref(s)*] )

## Return Value

Returns the volume indices as a a vector of three long integers. If the selected point is not within the volume, this function returns [-1,-1,-1].

## Arguments

### Win

The IDLgrWindow object from which the Z-buffer is to be used.

### View

The IDLgrView object that contains the volume.

### Point

The [*x*, *y*] viewport coordinates of the point chosen.

## Keywords

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a voxel coordinate. Each path object reference specified with this keyword must contain an alias. The voxel coordinate is computed for the version of the object falling within the specified path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## Version History

Introduced: 5.0

# IDLgrVolume::SetProperty

The IDLgrVolume::SetProperty procedure method sets the value of a property or group of properties for the volume.

## Syntax

*Obj* -> [IDLgrVolume::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrVolume Properties” on page 3657 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrVRML

The IDLgrVRML object allows you to save the contents of an Object Graphics hierarchy into a VRML 2.0 format file. The graphics tree can only contain a single view due to limitations in the VRML specification. The resulting VRML file is interactive and allows you to explore the geometry interactively using a VRML browser.

**Note**

Objects or subclasses of this type can not be saved or restored.

Aspect ratios are difficult to duplicate as they can be browser dependent. The object is limited to the primitives supported by VRML. Texture maps (and images) will be inlined into the output file. While this will generate large VRML files, the files are fully self-contained.

Several entities cannot be translated perfectly. These include:

## IDLgrImage objects

Rotation and Z buffer behavior are not completely supported. Image objects will be converted into texture mapped polygons. BLEND_FUNCTION is not completely supported (only binary srcAlpha,1-srcAlpha) This function is applied automatically if an alpha channel is present. It is also very browser dependent. Channel masks are not supported.

## IDLgrPolygon and IDLgrSurface objects

Hidden line/hidden point display, color and vertex color blending with texture colors, and bottom color are not supported. Shading may be browser dependent. Front face culling is not supported and back face culling is only supported at the browser's discretion.

## IDLgrLight objects

Lighting scope and intensity may be browser dependent.

## IDLgrText objects

Text using the ONGLASS property is only supported for the initial view.

## IDLgrViewgroup, IDLgrScene, IDLgrVolume objects

These objects are not supported.

### IDLgrPalette objects

Palette objects are simulated using an RGB color model.

### IDLgrPattern objects

Only solid or clear patterns are supported.

### IDLgrFont, IDLgrSymbol objects

The THICK property is not supported.

### IDLgrPolyline, IDLgrSymbol, IDLgrSurface, IDLgrPolygon and IDLgrPlot objects

Line attributes (thickness, linestyle) are not supported.

### IDLgrView objects

Z-clipping control, aspect ratio preservation, the LOCATION property, and orthographic projections are not supported.

### Destination objects

The COLOR_MODEL property is not fully supported in Indexed Color mode, when using a SHADER_RANGE (an RGB model will be substituted instead). The QUALITY property is not supported.

## Superclasses

IDLitComponent

## Creation

See “IDLgrVRML::Init” on page 3702.

## Properties

Objects of this class have the following properties. See “IDLgrVRML Properties” on page 3687 for details on individual properties.

- ALL
- COLOR_MODEL

- DIMENSIONS
- FILENAME
- GRAPHICS_TREE
- N_COLORS
- PALETTE
- QUALITY
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS
- UNITS
- WORLDINFO
- WORLDTITLE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrVRML::Cleanup
- IDLgrVRML::Draw
- IDLgrVRML::GetDeviceInfo
- IDLgrVRML::GetFontnames
- IDLgrVRML::GetProperty
- IDLgrVRML::GetTextDimensions
- IDLgrVRML::Init
- IDLgrVRML::SetProperty

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.1

# IDLgrVRML Properties

IDLgrVRML objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrVRML::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrVRML::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrVRML::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the retrievable properties associated with this object.

| | | | |
|---|---|---|---|
| **Property Type** | Structure | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## COLOR_MODEL

An integer value that determines whether to use the indexed color model for the buffer:

- 0 = RGB (the default)
- 1 = Color indexed.

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Color model | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## DIMENSIONS

A two-element integer vector of the form [*width, height*] to specify the dimensions of the window in units specified by the UNITS property. The default is [640,480].

**Note**

The only use of this property is to support the use of normalized coordinates for the dimensions of the IDLgrView object passed to the IDLgrVRML::Draw method..

| | | | |
|---|---|---|---|
| **Property Type** | Integer vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## FILENAME

A string that specifies the name of a file into which the vector data will be saved. The default is `idl.wrl`..

| | | | |
|---|---|---|---|
| **Property Type** | String | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## GRAPHICS_TREE

An object reference of type IDLgrView. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object. .

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## N_COLORS

An integer that specifies the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to indexed.

| **Property Type** | INTEGER | | |
|---|---|---|---|
| **Name String** | Number of colors | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) that specifies the red, green, and blue values that are to be loaded into the buffer's color lookup table.

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## QUALITY

An integer indicating the rendering quality at which graphics are to be drawn to the buffer. Valid values are:

- 0=Low
- 1=Medium
- 2=High (the default).
- In a property sheet, this property appears as an enumerated list with the following options:
- Low
- Medium

- High

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Quality | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RESOLUTION

A two-element floating-point vector of the form [*xres*, *yres*] specifying the device resolution in centimeters per pixel.

**Note**

This property is used for text scaling and partial aspect ratio preservation only. The default value is [0.0352778, 0.0352778] (72 DPI).

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Resolution | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## SCREEN_DIMENSIONS

A two-element integer vector of the form [*width*, *height*] specifying the dimensions of the overall screen dimensions for the screen with which this object associated. The screen dimensions are measured in device units..

| **Property Type** | Integer vector | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## UNITS

An integer that indicates the units of measure for the DIMENSIONS property. Valid values are:

- 0 = Device (the default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized (relative to 1600 x 1200)..

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## WORLDINFO

A list of strings for the info field of the VRML WorldInfo node. The default is the null string, ''.

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## WORLDTITLE

A string containing the title for the VRML WorldInfo node, TITLE field. The default is `'IDL VRML file'`.

| **Property Type** | String | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

# IDLgrVRML::Cleanup

The IDLgrVRML::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrVRML::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrVRML::Draw

The IDLgrVRML::Draw procedure method draws the given picture to this graphics destination.

## Syntax

*Obj* -> [IDLgrVRML::]Draw [, *Picture*]

## Arguments

### Picture

The view (an instance of an IDLgrView object) to be drawn. If the view has a LOCATION property, it is ignored.

## Keywords

None

## Version History

Introduced: 5.1

# IDLgrVRML::GetDeviceInfo

The IDLgrVRML::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=1 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

## Syntax

*Obj* -> [IDLgrVRML::]GetDeviceInfo [, ALL=*variable*]
[, MAX_NUM_CLIP_PLANES=*variable*]
[, MAX_TEXTURE_DIMENSIONS=*variable*]
[, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
[, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

## Arguments

None

## Keywords

### ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

### MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

### MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_TEXTURE_DIMENSIONS* contains a two element integer array that specifies the maximum texture size supported by the device.

### MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, *MAX_VIEWPORT_DIMENSIONS* contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

### NAME

Set this keyword equal to a named variable. Upon return, *NAME* contains the name of the rendering device as a string.

### NUM_CPUS

Set this keyword equal to a named variable. Upon return, *NUM_CPUS* contains an integer that specifies the number of CPUs that are known to, and available to IDL.

**Note**

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

### VENDOR

Set this keyword equal to a named variable. Upon return, *VENDOR* contains the name of the rendering device creator as a string.

### VERSION

Set this keyword equal to a named variable. Upon return, *VERSION* contains the version of the rendering device driver as a string.

## Version History

Introduced: 5.1

MAX_NUM_CLIP_PLANES keyword: 5.6

# IDLgrVRML::GetFontnames

The IDLgrVRML::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix H, "Fonts" for more information.

## Syntax

*Result* = *Obj* ->[IDLgrVRML::]GetFontnames( *FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*] )

## Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

## Arguments

### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name, such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

## Keywords

### IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

Introduced: 5.1

# IDLgrVRML::GetProperty

The IDLgrVRML::GetProperty procedure method retrieves the value of a property or group of properties for the VRML object.

## Syntax

*Obj* -> [IDLgrVRML::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under "IDLgrVRML Properties" on page 3687 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

## Version History

Introduced: 5.1

# IDLgrVRML::GetTextDimensions

The IDLgrVRML::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

## Syntax

*Result* = *Obj* ->[IDLgrVRML::]GetTextDimensions( *TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*] )

## Return Value

Returns a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units.

## Arguments

### TextObj

The object reference to a text or axis object for which the text dimensions are requested.

## Keywords

### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values represent the distance to travel (parallel to the UPDIR vector) from the text baseline to reach the bottom of the lowest descender in the string. All values will be negative numbers, or zero. This keyword is valid only if *TextObj* is an IDLgrText object.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If

this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrVRML::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## Version History

Introduced: 5.1

# IDLgrVRML::Init

The IDLgrVRML::Init function method initializes the VRML object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrVRML' [, *PROPERTY*=*value*])

or

*Result* = *Obj* -> [IDLgrVRML::]Init([*PROPERTY*=*value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrVRML Properties" on page 3687 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.1

# IDLgrVRML::SetProperty

The IDLgrVRML::SetProperty procedure method sets the value of a property or group of properties for the VRML world.

## Syntax

*Obj* -> [IDLgrVRML::]SetProperty[, *PROPERTY*=*value*]

## Arguments

None

## Keywords

Any property listed under “IDLgrVRML Properties” on page 3687 that contains the word “Yes” in the “Set” column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.1

# IDLgrWindow

A window object is a representation of an on-screen area on a display device that serves as a graphics destination.

**Note**

Objects or subclasses of this type can not be saved or restored.

### Note on Window Size Limits

The OpenGL libraries IDL uses impose limits on the maximum size of a drawable area. The limits are device-dependent — they depend both on your graphics hardware and the setting of the RENDERER property. Currently, the smallest maximum drawable area on any IDL platform is 1280 x 1024 pixels; the limit on your system may be larger.

## Superclasses

IDLitComponent

## Creation

See “IDLgrWindow::Init” on page 3729.

## Properties

Objects of this class have the following properties. See “IDLgrWindow Properties” on page 3707 for details on individual properties.

- ALL
- CURRENT_ZOOM
- DISPLAY_NAME (X Only)
- IMAGE_DATA
- N_COLORS
- QUALITY
- RENDERER
- RETAIN
- COLOR_MODEL
- DIMENSIONS
- GRAPHICS_TREE
- LOCATION
- PALETTE
- REGISTER_PROPERTIES
- RESOLUTION
- SCREEN_DIMENSIONS

- TITLE
- VIRTUAL_DIMENSIONS
- ZBUFFER_DATA
- UNITS
- VISIBLE_LOCATION

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- IDLgrWindow::Cleanup
- IDLgrWindow::Draw
- IDLgrWindow::Erase
- IDLgrWindow::GetContiguousPixels
- IDLgrWindow::GetDeviceInfo
- IDLgrWindow::GetFontnames
- IDLgrWindow::GetProperty
- IDLgrWindow::GetTextDimensions
- IDLgrWindow::Iconify
- IDLgrWindow::Init
- IDLgrWindow::PickData
- IDLgrWindow::Read
- IDLgrWindow::Select
- IDLgrWindow::SetCurrentCursor
- IDLgrWindow::SetProperty
- IDLgrWindow::Show

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDLgrWindow Properties

IDLgrWindow objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via IDLgrWindow::GetProperty. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via IDLgrWindow::Init. Properties with the word “Yes” in the “Set” column in the property table can be set via IDLgrWindow::SetProperty.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## ALL

An anonymous structure containing the values of all of the properties associated with the *state* of this object. State information about the object includes things like color, range, tick direction, etc., but not image, vertex, or connectivity data, or user values.

**Note**

The fields of this structure may change in subsequent releases of IDL.

| **Property Type** | Structure | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## COLOR_MODEL

An integer value that determines whether to use indexed color as the color model for the window:

- 0 = RGB (default)
- 1 = Color Index

**Note**

For some X11 display situations, IDL may not be able to support a color index model destination object in object graphics. We do, however, guarantee that an RGB color model destination will be available for all display situations..

In a property sheet, this property appears as an enumerated list with the following options:

- RGB
- Indexed color

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Color model | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## CURRENT_ZOOM

A floating-point value that represents the current zoom factor associated with this window.

| | | | |
|---|---|---|---|
| **Property Type** | FLOAT | | |
| **Name String** | Zoom factor | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** Yes |

## DIMENSIONS

A two-element integer vector of the form [*width*, *height*] to specify the dimensions of the window in units specified by the UNITS property. By default, if no value is specified for DIMENSIONS, IDL uses the value of the “Default Window Width” and “Default Window Height” preferences set in the IDL Development Environment’s (IDLDE) Preferences dialog. If there is no preference file for the IDLDE, the DIMENSIONS property is set equal to one quarter of the screen size. There are limits on the maximum size of an IDLgrWindow object; see “Note on Window Size Limits” on page 3705 for details.

**Note**

Changing DIMENSIONS properties is merely a request and may be ignored for various reasons. .

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Dimensions | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## DISPLAY_NAME (X Only)

A string that specifies the name of the X Windows display on which the window is to appear.

| | | | |
|---|---|---|---|
| **Property Type** | STRING | | |
| **Name String** | Display name | | |
| **Get:** Yes | **Set:** Yes | **Init:** No | **Registered:** Yes |

## GRAPHICS_TREE

An object reference of type IDLgrScene, IDLgrViewgroup, or IDLgrView. If this property is set to a valid object reference, calling the Draw method on the destination object with no arguments will cause the object reference associated with this property to be drawn. If this object is valid and the destination object is destroyed, this object reference will be destroyed as well. By default the GRAPHICS_TREE property is set equal to the null-object.

| | | | |
|---|---|---|---|
| **Property Type** | Object reference | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** No |

## IMAGE_DATA

A byte array representing the image that is currently displayed in the window. If the window object uses an RGB color model, the returned array will have dimensions (3, *winXSize*, *winYSize*), or (4, *winXSize*, *winYSize*) if an alpha channel is included. If the window object uses an Indexed color model, the returned array will have dimensions

(*winXSize*, *winYSize*). See "IDLgrWindow::Read" on page 3734 for more information.

| **Property Type** | Byte array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## LOCATION

A two-element floating-point vector of the form [*x*, *y*] to specify the location of the upper lefthand corner of the window relative to the display screen, in units specified by the UNITS property. By default, the window is positioned at one of four quadrants on the display screen, and the location is measured in device units.

**Note**

Changing LOCATION properties is merely a request and may be ignored for various reasons. LOCATION may be adjusted to take into account window decorations..

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Location | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## N_COLORS

An integer value that specifies the number of colors (between 2 and 256) to be used if COLOR_MODEL is set to Indexed (1). This property is ignored if COLOR_MODEL is set to RGB (0).

**Note**

If COLOR_MODEL is set to Color Index (1), setting N_COLORS is treated as a request to your operating system. You should always check the actual number of available colors for any Color Indexed destination with the

IDLgrWindow::GetProperty method. The actual number of available colors depends on your system and also on how you have used IDL..

| | | | |
|---|---|---|---|
| **Property Type** | INTEGER | | |
| **Name String** | Number of colors | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## PALETTE

An object reference to a palette object (an instance of the IDLgrPalette object class) to specify the red, green, and blue values that are to be loaded into the graphics destination's color lookup table, applicable if the Indexed color model is used..

This property is registered as a user-defined property, but it is hidden by default.

| | | | |
|---|---|---|---|
| **Property Type** | USERDEF | | |
| **Name String** | Color palette | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## QUALITY

An integer indicating the rendering quality at which graphics are to be drawn to this destination. Valid values are:

- 0 = Low
- 1 = Medium
- 2 = High (default)..

In a property sheet, this property appears as an enumerated list with the following options:

- Low
- Medium

- High

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Draw quality | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## REGISTER_PROPERTIES

A Boolean value that determines whether to register properties available for this object. Set this property to automatically register the following properties of the object for display in a property sheet. This property is useful mainly when creating iTools. By default, no properties are registered.

| | | | |
|---|---|---|---|
| **Property Type** | Boolean | | |
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## RENDERER

An integer value indicating which graphics renderer to use when drawing objects within the window. Valid values are:

- 0 = Platform native OpenGL
- 1 = IDL's software implementation

By default, your platform's native OpenGL implementation is used. If your platform does not have a native OpenGL implementation, IDL's software implementation is used regardless of the value of this property. See "Hardware vs. Software Rendering" in Chapter 34 of the *Using IDL* manual for details. Your choice of renderer may also affect the maximum size of an IDLgrWindow object; see "Note on Window Size Limits" on page 3705 for details.

In a property sheet, this property appears as an enumerated list with the following options:

- OpenGL

- Software.

| **Property Type** | ENUMLIST | | |
|---|---|---|---|
| **Name String** | Renderer | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## RESOLUTION

A floating-point vector of the form [*xres*, *yres*] reporting the pixel resolution, measured in centimeters per pixel. This value is stored in double precision.

| **Property Type** | FLOAT | | |
|---|---|---|---|
| **Name String** | Resolution | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** Yes |

## RETAIN

An integer value that specifies how backing store should be handled for the window. By default, if no value is specified for RETAIN, IDL uses the value of the “Backing Store” preference set in the IDL Development Environment’s (IDLDE) Preferences dialog. If there is no preference file for the IDLDE (that is, if you always use IDL in plain tty mode), the RETAIN property is set equal to 0 by default.

- 0 = No backing store.
- 1 = The server or window system is requested to provide the backing store. Note that requesting backing store from the server is only a request; backing store may not be provided in all situations.
- 2 = Requests that IDL provide the backing store directly. In some situations, IDL can not provide this backing store in Object Graphics. To see if IDL provided backing store, query the RETAIN property of IDLgrWindow::GetProperty. IDL may also alter the RENDERER property while attempting to provide backing store.

In IDL Object Graphics, it is almost always best to disable backing store (that is, set the RETAIN property equal to zero). This is because drawing to an off-screen pixmap (which is what happens when backing store is enabled) almost always bypasses any hardware graphics acceleration that may be available, causing all rendering to be done in software. To ensure that windows are redrawn properly,

enable the generation of expose events on the WIDGET_DRAW window and redraw the window explicitly when an expose event is received.

**Note**

If you are using software rendering (that is, the RENDERER property is set equal to one), IDL will refresh the window automatically regardless of the setting of the RETAIN property..

In a property sheet, this property appears as an enumerated list with the following options:

- No backing
- Server/Window
- IDL

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Retain | | |
| **Get:** Yes | **Set:** No | **Init:** Yes | **Registered:** Yes |

## SCREEN_DIMENSIONS

A two-element floating-point vector of the form [*width*, *height*] specifying the dimensions of the overall screen dimensions for the screen with which this window is associated. The screen dimensions are measured in device units.

**Note**

The maximum screen dimension size depends on the graphics device..

| | | | |
|---|---|---|---|
| **Property Type** | Floating-point vector | | |
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

## TITLE

A string that represents the title of the window..

| | | | |
|---|---|---|---|
| **Property Type** | STRING | | |
| **Name String** | Title | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## UNITS

An integer value that indicates the units of measure for the LOCATION and DIMENSIONS properties. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the screen.

**Note**

If you set the value of the UNITS property (using the SetProperty method) without also setting the value of the LOCATION and DIMENSIONS properties, IDL will convert the current size and location values into the new units..

In a property sheet, this property appears as an enumerated list with the following options:

- Device
- Inches
- Centimeters
- Normalized

| | | | |
|---|---|---|---|
| **Property Type** | ENUMLIST | | |
| **Name String** | Units | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## VIRTUAL_DIMENSIONS

A two-element integer vector, [width, height], specifying the dimensions of the virtual canvas for this window. The default is [0,0], indicating that the virtual canvas dimensions should match the visible dimensions (as specified via the DIMENSIONS keyword).

This property is registered as a user-defined property, but it is hidden by default.

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Virtual dimensions | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## VISIBLE_LOCATION

A two-element integer vector, [x,y], specifying the lower left location of the visible portion of the canvas (relative to the virtual canvas).

This property is registered as a user-defined property, but it is hidden by default..

| **Property Type** | USERDEF | | |
|---|---|---|---|
| **Name String** | Visible location | | |
| **Get:** Yes | **Set:** Yes | **Init:** Yes | **Registered:** Yes |

## ZBUFFER_DATA

A floating-point array representing the zbuffer that is currently within the buffer. The returned array will have dimensions (*xdim*, *ydim*).

| **Property Type** | Floating-point array | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** Yes | **Set:** No | **Init:** No | **Registered:** No |

# IDLgrWindow::Cleanup

The IDLgrWindow::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj* -> [IDLgrWindow::]Cleanup (*Only in subclass' Cleanup method*.)

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrWindow::Draw

The IDLgrWindow::Draw procedure method draws the specified scene or view object to this graphics destination.

**Note**

Objects are drawn to the destination device in the order that they are added to the model, view, viewgroup, or scene object that contains them.

# Syntax

*Obj* -> [IDLgrWindow::]Draw [, *Picture*] [, CREATE_INSTANCE={1 | 2}] [, /DRAW_INSTANCE]

# Arguments

## Picture

The view (an instance of an IDLgrView object), viewgroup (an instance of an IDLgrViewgroup object), or scene (an instance of an IDLgrScene object) to be drawn.

# Keywords

## CREATE_INSTANCE

Set this keyword equal to one specify that this scene or view is the unchanging part of a drawing. Some destinations can make an instance from the current window contents without having to perform a complete redraw. If the view or scene to be drawn is identical to the previously drawn view or scene, this keyword can be set equal to 2 to hint the destination to create the instance from the current window contents if it can.

## DRAW_INSTANCE

Set this keyword to specify that this scene or view is the changing part of a drawing. It is overlaid on the result of the most recent CREATE_INSTANCE draw.

# Version History

Introduced: 5.0

# IDLgrWindow::Erase

The IDLgrWindow::Erase procedure method erases the entire contents of the window.

## Syntax

*Obj* -> [IDLgrWindow::]Erase [, COLOR=*index or RGB vector*]

## Arguments

None

## Keywords

### COLOR

Set this keyword to the color to be used for the erase. The color may be specified as a color lookup table index or as an RGB vector. The default erase color is white.

## Version History

Introduced: 5.0

# IDLgrWindow::GetContiguousPixels

The IDLgrWindow::GetContiguousPixels function method returns an array of long integers whose length is equal to the number of colors available in the index color mode (that is, the value of the N_COLORS property).

The returned array marks contiguous pixels with the ranking of the range's size. This means that within the array, the elements in the largest available range are set to zero, the elements in the second-largest range are set to one, etc. Use this range to set an appropriate colormap for use with the SHADE_RANGE property of the IDLgrSurface and IDLgrPolygon object classes.

To get the largest contiguous range, you could use the following IDL command:

```
result = obj -> GetContiguousPixels()
Range0 = WHERE(result EQ 0)
```

A contiguous region in the colormap can be increasing or decreasing in values. The following would be considered contiguous:

```
[0,1,2,3,4]
[4,3,2,1,0]
```

## Syntax

*Result* = *Obj* -> [IDLgrWindow::]GetContiguousPixels()

## Return Value

Returns an array of long integers whose length is equal to the number of colors available in the index color mode.

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrWindow::GetDeviceInfo

The IDLgrWindow::GetDeviceInfo procedure method returns information which allows IDL applications to intelligently make decisions for optimal performance. For example, it allows an application to determine if RENDERER=0 is actually implemented in hardware. It also allows applications to make optimal quality decisions when dynamically building texture maps.

## Syntax

*Obj* -> [IDLgrWindow::]GetDeviceInfo [, ALL=*variable*]
[, MAX_NUM_CLIP_PLANES=*variable*]
[, MAX_TEXTURE_DIMENSIONS=*variable*]
[, MAX_VIEWPORT_DIMENSIONS=*variable*] [, NAME=*variable*]
[, NUM_CPUS=*variable*] [, VENDOR=*variable*] [, VERSION=*variable*]

## Arguments

None

## Keywords

### ALL

Set this keyword to a named variable which, upon return, contains a structure with the values of all the device information keywords as fields.

### MAX_NUM_CLIP_PLANES

Set this keyword to a named variable that upon return will contain an integer that specifies the maximum number of user-defined clipping planes supported by the device.

### MAX_TEXTURE_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_TEXTURE_DIMENSIONS contains a two element integer array that specifies the maximum texture size supported by the device.

### MAX_VIEWPORT_DIMENSIONS

Set this keyword equal to a named variable. Upon return, MAX_VIEWPORT_DIMENSIONS contains a two element integer array that specifies the maximum size of a graphics display supported by the device.

### NAME

Set this keyword equal to a named variable. Upon return, NAME contains the name of the rendering device as a string.

### NUM_CPUS

Set this keyword equal to a named variable. Upon return, NUM_CPUS contains an integer that specifies the number of CPUs that are known to, and available to IDL.

**Note**

The NUM_CPUS keyword accurately returns the number of CPUs for the SGI IRIX, SUN, and Microsoft Windows platforms. For platforms other than these, the number returned may not reflect the actual number of CPUs available to IDL in the current system.

### VENDOR

Set this keyword equal to a named variable. Upon return, VENDOR contains the name of the rendering device creator as a string.

### VERSION

Set this keyword equal to a named variable. Upon return, VERSION contains the version of the rendering device driver as a string.

## Version History

Introduced: 5.0

MAX_NUM_CLIP_PLANES keyword: 5.6

# IDLgrWindow::GetFontnames

The IDLgrWindow::GetFontnames function method returns the list of available fonts that can be used in IDLgrFont objects. This method will only return the names of the available TrueType fonts. Hershey fonts will not be returned; see Appendix H, "Fonts" for more information.

## Syntax

*Result* = *Obj* -> [IDLgrWindow::]GetFontnames(*FamilyName* [, IDL_FONTS={0 | 1 | 2}] [, STYLES=*string*] )

## Return Value

Returns the list of available fonts that can be used in IDLgrFont objects.

## Arguments

### FamilyName

A string representing the name of the font family to which all of the returned fonts must belong. The string may be a fully specified family name—such as "Helvetica". You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. To return all available family names, use "*".

## Keywords

### IDL_FONTS

Set this keyword to specify where to search for fonts that IDL may use. Set IDL_FONT to 1 to select only fonts installed by IDL and to 2 to select only fonts detected in the host operating system. The default value is 0, specifying that both IDL and operating system fonts should be returned.

### STYLES

Set this keyword to a string specifying the styles that are to be matched by the returned font names. You can set STYLES to a fully specified style string, such as "Bold Italic". If you set STYLES to the null string, ' ', only fontnames without style modifiers will be returned. You can use both "*" and "?" as wildcard characters, matching any number of characters or one character respectively. The default value is

the string, “*”, which returns all fontnames containing the *FamilyName* argument, with or without style modifiers.

## Version History

Introduced: 5.0

# IDLgrWindow::GetProperty

The IDLgrWindow::GetProperty procedure method retrieves the value of a property or group of properties for the window.

## Syntax

*Obj* -> [IDLgrWindow::]GetProperty[, *PROPERTY*=*variable*]

## Arguments

None

## Keywords

Any property listed under "IDLgrWindow Properties" on page 3707 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

Any keyword not recognized is passed to this object's superclass.

## Version History

Introduced: 5.0

# IDLgrWindow::GetTextDimensions

The IDLgrWindow::GetTextDimensions function method retrieves the dimensions of a text or axis object that will be rendered in a window. The result is a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units. If the object specified is an axis object, the result encompasses the tick labels and the title of the axis (if any).

## Syntax

*Result* = *Obj* -> [IDLgrWindow::]GetTextDimensions( *TextObj* [, DESCENT=*variable*] [, PATH=*objref(s)*] )

## Return Value

Returns a 3-element double-precision floating-point vector [*xDim*, *yDim*, *zDim*] representing the dimensions of the text or axis object, measured in data units.

## Arguments

### TextObj

The object reference to a text or axis object for which the text dimensions are requested.

## Keywords

### DESCENT

Set this keyword equal to a named variable that will contain an array of double-precision floating-point values (one for each string in the IDLgrText object). The values are the distance to travel (parallel to the UPDIR direction) from the baseline to reach the bottom of all the descenders for the string; the values will be negative or 0. This keyword is only valid if *TextObj* is of the class IDLgrText.

### PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to compute the text dimensions. Each path object reference specified with this keyword must contain an alias. The text dimensions are computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current

object to the top of the graphics hierarchy and no alias paths are pursued. If IDLgrWindow::GetTextDimensions is called from within a Draw method and the PATH keyword is not set, the alias path used to find the object during the draw is used, rather than the PARENT path.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## Version History

Introduced: 5.0

# IDLgrWindow::Iconify

The IDLgrWindow::Iconify procedure method iconifies or de-iconifies the window.

**Note**

Iconification under window systems is solely handled by the window manager; client applications, such as IDL, do not have the capability to manage icons. The Iconify method provides a hint to the window manager, which applies the information as it sees fit.

## Syntax

*Obj* -> [IDLgrWindow::]Iconify, *IconFlag*

## Arguments

### IconFlag

Set *IconFlag* to 1 (one) to iconify the window or to 0 (zero) to restore the window. If the window is already restored, it is brought to the front of the window stack.

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrWindow::Init

The IDLgrWindow::Init function method initializes the window object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDLgrWindow' [, *PROPERTY=value*])

or

*Result = Obj ->* [IDLgrWindow::]Init([, *PROPERTY=value*])
(*Only in a subclass' Init method*.)

## Return Value

When this method is called indirectly, as part of the call to the OBJ_NEW function, the return value is an object reference to the newly-created object.

When called directly within a subclass Init method, the return value is 1 if initialization was successful, or zero otherwise.

## Arguments

None

## Keywords

Any property listed under "IDLgrWindow Properties" on page 3707 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

All other keywords are passed to the superclass of this object.

## Version History

Introduced: 5.0

# IDLgrWindow::PickData

The IDLgrWindow::PickData function method maps a point in the two-dimensional device space of the window to a point in the three-dimensional data space of an object tree. The resulting 3-D data space coordinates are returned in a user-specified variable. The PickData function returns one if the specified location in the window's device space "hits" a graphic object, or zero if no object was "hit". PickData returns -1 if the point selected falls outside of the specified view or window.

## Syntax

*Result* = *Obj* -> [IDLgrWindow::]PickData( *View*, *Object*, *Location*, *XYZLocation* [, DIMENSIONS=*[w,h]*] [, PATH=*objref(s)*] [, PICK_STATUS=*variable*])

## Return Value

Returns 1 if the specified location in the window's device space "hits" a graphic object, or 0 if no object was hit. Returns -1 if the point selected falls outside the specified view or window.

## Arguments

### View

The object reference of an IDLgrView object that contains the object being picked.

### Object

The object reference of a model or atomic graphic object from which the data space coordinates are being requested.

### Location

A two-element vector [*x*, *y*] specifying the location in the window's device space of the point to pick data from.

### XYZLocation

A named variable that will contain the three-dimensional double-precision floating-point data space coordinates of the picked point. Note that the value returned in this variable is a location, not a data value.

**Note**

If the atomic graphic object specified as the target has been transformed using either the LOCATION or DIMENSIONS properties (this is only possible with IDLgrAxis, IDLgrImage, and IDLgrText objects), these transformations will *not* be included in the data coordinates returned by the PickData function. This means that you may need to re-apply the transformation accomplished by specifying LOCATION or DIMENSIONS once you have retrieved the data coordinates with PickData. This situation does not occur if you transform the axis, text, or image object using the [XYZ]COORD_CONV properties.

# Keywords

## DIMENSIONS

Set this keyword to a two-element array [*w, h*] to specify data picking should occur for all device locations that fall within a *pick box* of these dimensions. The pick box will be centered about the coordinates [*x, y*] specified in the *Location* argument, and will occupy the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/2), y+(h/2))
```

By default, the pick box covers a single pixel. The array returned via the *XYZLocation* argument will have dimensions [*3, w, h*].

## PATH

Set this keyword to a single object reference or a vector of object references. This keyword specifies the path in the graphics hierarchy to map the device position to a data space coordinate. Each path object reference specified with this keyword must contain an alias. The data space coordinate is computed for the version of the object falling within that path. If this keyword is not set, the PARENT properties determine the path from the current object to the top of the graphics hierarchy and no alias paths are pursued.

**Note**

For more information on aliases, refer to the ALIAS keyword in IDLgrModel::Add.

## PICK_STATUS

Set this keyword to a named variable that will contain “hit” information for each pixel in the pick box. If the DIMENSIONS keyword is not set, the PICK_STATUS will be a scalar value exactly matching the *Result* of the method call. If the

DIMENSIONS keyword is set, the PICK_STATUS variable will be an array matching the dimensions of the pick box. Each value in the PICK_STATUS array corresponds to a pixel in the pick box, and will be set to one of the following values:

| Value | Description |
|---|---|
| -1 | The pixel falls outside of the window's viewport. |
| 0 | No graphic object is "hit" at that pixel location. |
| 1 | A graphic object is "hit" at that pixel location. |

*Table 8-8: PICK_STATUS Keyword Values*

## Version History

Introduced: 5.0

PICK_STATUS keyword: 5.6

# IDLgrWindow::Read

The IDLgrWindow::Read function method reads an image from a window. The returned value is an instance of the IDLgrImage object class.

## Syntax

*Result* = *Obj* -> [IDLgrWindow::]Read()

## Arguments

None

## Keywords

None

## Version History

Introduced: 5.0

# IDLgrWindow::Select

The IDLgrWindow::Select function method returns a list of objects selected at a specified location. If no objects are selected, the Select function returns -1.

**Note**

IDL returns a maximum of 512 objects. This maximum may be smaller if any of the objects are contained in deep model hierarchies. Because of this limit, it is possible that not all objects eligible for selection will appear in the list.

## Syntax

*Result* = *Obj* -> [IDLgrWindow::]Select( *Picture, XY* [, DIMENSIONS=*[width, height]*] [, /ORDER] [, UNITS={0 | 1 | 2 | 3}] )

## Return Value

Returns a list of objects selected at a specified location. Returns -1 if no objects are selected.

## Arguments

### Picture

The view or scene (an instance of the IDLgrView, IDLgrViewgroup, or IDLgrScene class) whose children are among the candidates for selection.

If the first argument is a scene, then the returned object list will contain one or more views. If the first argument is a view, the list will contain atomic graphic objects (or model objects which have their SELECT_TARGET property set). Objects are returned in order, according to their distance from the viewer. The closer an object is to the viewer, the lower its index in the returned object list. If multiple objects are at the same distance from the viewer (views in a scene or 2-D geometry), the first object drawn will appear at a lower index in the list. (The ORDER keyword can be used to change this behavior.)

### XY

A two-element array defining the center of the selection box in device space. By default, the selection box is 3 pixels by 3 pixels.

# Keywords

## DIMENSIONS

Set this keyword to a two-element array [*w*, *h*] to specify that the selection box will have a width *w* and a height *h*, and will be centered about the coordinates [*x*, *y*] specified in the *XY* argument. The box occupies the rectangle defined by:

```
(x-(w/2), y-(h/2)) - (x+(w/1), y+(h/2))
```

Any object that intersects this box is considered to be selected. By default, the selection box is 3 pixels by 3 pixels.

## ORDER

Set this keyword to control how objects that are the same distance from the viewer are ordered in the selection list. If ORDER=0 (the default), the order of objects in the selection list will be the same as the order in which the objects are drawn. If ORDER=1, the order of objects in the selection list will be the reverse of the order in which they are drawn. This keyword has no affect on the ordering of objects that are not at the same distance from the viewer.

**Tip**

If you are using DEPTH_TEST_FUNCTION=4 (“less than or equal”) on your graphics objects, set ORDER=1 to return objects at the same depth in the order in which they appear visually.

## UNITS

Set this keyword to indicate the units of measure. Valid values are:

- 0 = Device (default)
- 1 = Inches
- 2 = Centimeters
- 3 = Normalized: relative to the dimensions of the graphics destination.

# Version History

Introduced: 5.0

# IDLgrWindow::SetCurrentCursor

The IDLgrWindow::SetCurrentCursor procedure method sets the current cursor image to be used while positioned over a drawing area.

## Syntax

*Obj*->[IDLgrWindow::]SetCurrentCursor [, *CursorName*] [, IMAGE=*16 x 16 bitmap*] [, MASK=*16 x 16 bitmap*] [, HOTSPOT=*[x, y]*]

**X Windows Keywords:** [, STANDARD=*index*]

## Arguments

### CursorName

A string that specifies which built-in cursor to use. This argument is ignored if any keywords to this routine are set. This string can either be a name provided to the REGISTER_CURSOR routine or one of the following:

- ARROW
- CROSSHAIR
- ICON
- IBEAM
- MOVE
- ORIGINAL
- SIZE_NE
- SIZE_NW
- SIZE_SE
- SIZE_SW
- SIZE_NS
- SIZE_EW
- UP_ARROW

## Keywords

### IMAGE

Set this keyword to a 16x16 column bitmap, contained in a 16-element short integer vector, specifying the cursor pattern. The offset from the upper-left pixel to the point that is considered the “hot spot” can be provided via the HOTSPOT keyword.

### MASK

When the IMAGE keyword is set, the MASK keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the IMAGE that should be seen and bits that are not are “masked out”.

### HOTSPOT

Set this keyword to a two-element vector specifying the [*x*, *y*] pixel offset of the cursor “hot spot”, the point which is considered to be the mouse position, from the upper left corner of the cursor image. This parameter is only applicable if IMAGE is provided. The cursor image is displayed top-down (the first row is displayed at the top).

### STANDARD (X Only)

Set this keyword to an X11 cursor font index to change the appearance of the cursor in the IDL graphics window to a glyph in this font. On non-X platforms, setting this keyword displays the crosshair cursor.

## Version History

Introduced: 5.0

CursorName argument: 5.6

# IDLgrWindow::SetProperty

The IDLgrWindow::SetProperty procedure method sets the value of a property or group of properties for the window.

## Syntax

*Obj* -> [IDLgrWindow::]SetProperty[, *PROPERTY=value*]

## Arguments

None

## Keywords

Any property listed under "IDLgrWindow Properties" on page 3707 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.0

# IDLgrWindow::Show

The IDLgrWindow::Show procedure method exposes or hides a window.

## Syntax

*Obj* -> [IDLgrWindow::]Show, *Position*

## Arguments

### Position

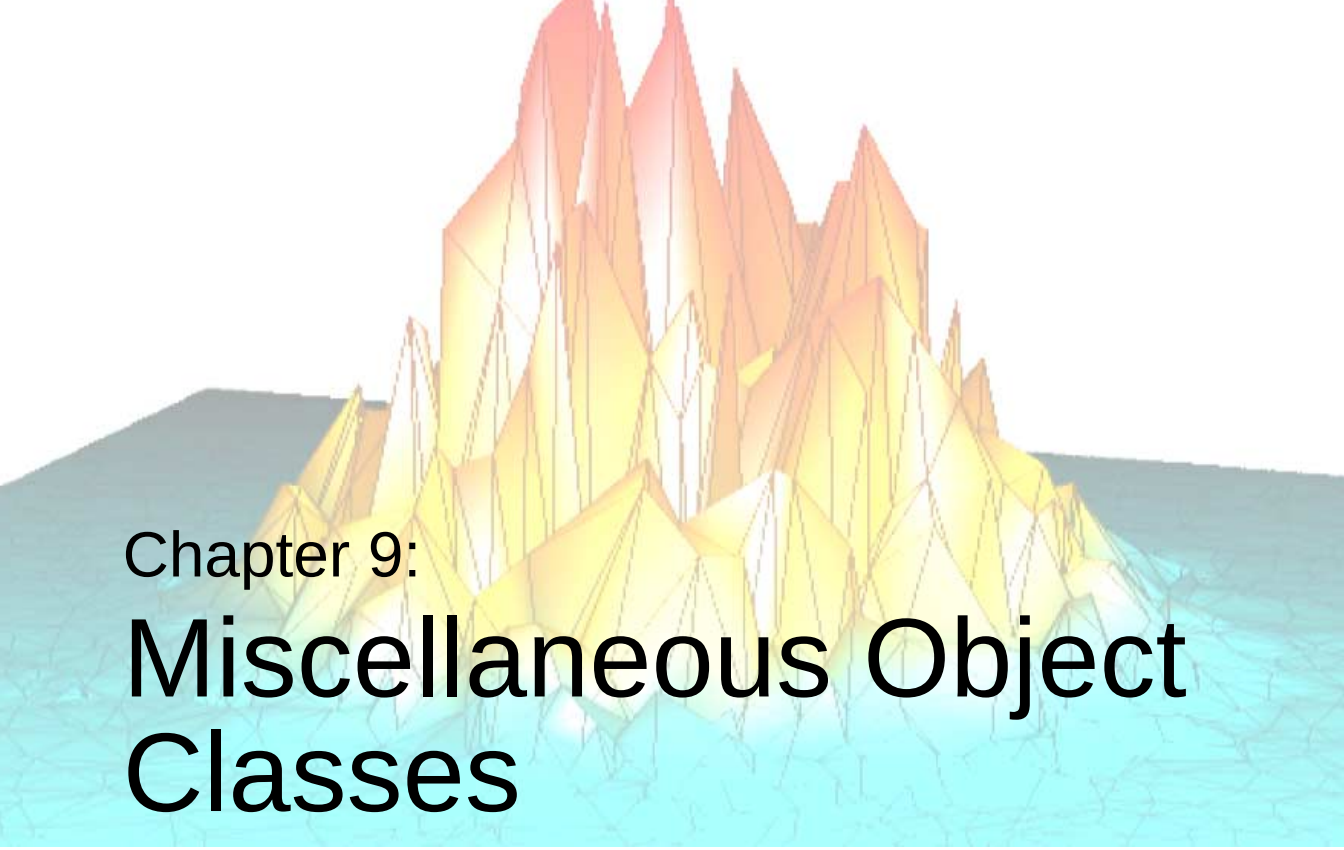
Set this argument equal to a non-zero value to expose the window, or to 0 to hide the window.

## Keywords

None

## Version History

Introduced: 5.0



# Chapter 9: Miscellaneous Object Classes

This chapter describes IDL's Container, COM, Java, and Trackball class libraries.

# IDL_Container

An IDL_Container object holds other objects. Destroying an IDL_Container object destroys any objects that have been added to the container via the Add method.

## Superclasses

This class has no superclasses.

## Creation

See “IDL_Container::Init” on page 3749.

## Properties

Objects of this class have no properties of their own.

## Methods

This class has the following methods:

- IDL_Container::Add
- IDL_Container::Cleanup
- IDL_Container::Count
- IDL_Container::Get
- IDL_Container::Init
- IDL_Container::IsContained
- IDL_Container::Move
- IDL_Container::Remove

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# IDL_Container Properties

Objects of this class have no properties of their own.

# IDL_Container::Add

The IDL_Container::Add procedure method adds one or more child objects to the container.

## Syntax

*Obj* -> [IDL_Container::]Add, *Objects* [POSITION=*index*]

## Arguments

### Objects

An object instance or array of object instances to be added to the container object.

## Keywords

### POSITION

Set this keyword equal to a scalar or array of zero-based index values. The number of elements specified must be equal to the number of object references specified by the *Objects* argument. Each index value specifies the position within the container at which a new object should be placed. The default is to add new objects at the end of the list of contained items.

## Examples

If the container has three objects, a new object will be placed at the fourth position. Since positions begin at zero, this would be equivalent to setting POSITION=3.

## Version History

Introduced: 5.0

# IDL_Container::Cleanup

The IDL_Container::Cleanup procedure method performs all cleanup on the object.

**Note**

Cleanup methods are special *lifecycle methods*, and as such cannot be called outside the context of object destruction. This means that in most cases, you cannot call the Cleanup method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Cleanup method from within the Cleanup method of the subclass.

## Syntax

OBJ_DESTROY, *Obj*

or

*Obj*`->` [IDL_Container::]Cleanup(*Only in subclass' Cleanup method*.)

## Arguments

None.

## Keywords

None.

## Version History

Introduced: 5.0

# IDL_Container::Count

The IDL_Container::Count function method returns the number of objects contained by the container object.

## Syntax

*Result* = *Obj* -> [IDL_Container::]Count()

## Arguments

None.

## Keywords

None.

## Version History

Introduced: 5.0

# IDL_Container::Get

The IDL_Container::Get function method returns an array of object references to objects in a container. Unless the ALL or POSITION keywords are specified, the first object in the container is returned. If no objects are found in the container, the Get function returns -1.

## Syntax

*Result* = *Obj* -> [IDL_Container::]Get ([, /ALL [, ISA=*class_name(s)*] | , POSITION=*index*] [COUNT=*variable*] )

## Arguments

None.

## Keywords

### ALL

Set this keyword to return an array of object references to all of the objects in the container.

### COUNT

Set this keyword equal to a named variable that will contain the number of objects selected by the function. If the ALL keyword is also specified, specifying this keyword is the same as calling the IDL_Container::Count method.

### ISA

Set this keyword equal to a class name or vector of class names. This keyword is used in conjunction with the ALL keyword. The ISA keyword filters the array returned by the ALL keyword, returning only the objects that inherit from the class or classes specified by the ISA keyword.

**Note**

This keyword is ignored if the ALL keyword is not provided.

### POSITION

Set this keyword equal to a scalar or array containing the zero-based indices of the positions of the objects to return.

## Version History

Introduced: 5.0

# IDL_Container::Init

The IDL_Container::Init function method initializes the container object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: If you write your own subclass of this class, you can call the Init method from within the Init method of the subclass.

## Syntax

*Obj* = OBJ_NEW('IDL_Container')

or

*Result* = *Obj* -> [IDL_Container::]Init( ) (*Only in a subclass' Init method*.)

## Arguments

None.

## Keywords

None.

## Version History

Introduced: 5.0

# IDL_Container::IsContained

The IDL_Container::IsContained function method returns true (1) if the specified object is in the container, or false (0) otherwise.

## Syntax

*Result* = *Obj* -> [IDL_Container::]IsContained( *Object* [, POSITION=*variable*] )

## Arguments

### Object

The object reference or vector of object references of the object(s) to search for in the container.

## Keywords

### POSITION

Set this keyword to a named variable that upon return will contain the position(s) at which (each of) the argument(s) is located within the container, or -1 if it is not contained.

## Version History

Introduced: 5.0

# IDL_Container::Move

The IDL_Container::Move procedure method moves an object from one position in a container to a new position. The order of the other objects in the container remains unchanged.

Positioning within a container controls the rendering order of the contained objects. The object whose location has the lowest index value is rendered first. If several objects are located at the same point in three-dimensional space, the object rendered first will occlude objects rendered later. Objects located “behind” other objects in three-dimensional space must be rendered before objects in front of them, even if the “front” objects are translucent.

## Syntax

*Obj* -> [IDL_Container::]Move, *Source*, *Destination*

## Arguments

### Source

The zero-based index of the current location of the object to be moved.

### Destination

The zero-based index of the location in the container where the object will reside after being moved.

## Keywords

None.

## Version History

Introduced: 5.0

# IDL_Container::Remove

The IDL_Container::Remove procedure method removes an object from the container.

## Syntax

*Obj* -> [IDL_Container::]Remove [, *Child_object* | , POSITION=*index* | , /ALL]

## Arguments

### Child_object

The object reference of the object to be removed from the container. If *Child_object* is not provided (and neither the ALL nor POSITION keyword are set), the first object in the container will be removed.

## Keywords

### ALL

Set this keyword to remove all objects from the container. If this keyword is set, the *Child_object* argument is not required.

### POSITION

Set this keyword equal to the zero-based index of the object to be removed. If the *Child_object* argument is supplied, this keyword is ignored.

## Version History

Introduced: 5.0

# IDLcomActiveX

The IDLcomActiveX object class creates an IDL object that encapsulates an ActiveX control. IDL provides data type and other translation services, allowing IDL programs to access the ActiveX control's methods and properties using standard IDL syntax.

For detailed information on using the IDLcomActiveX object, see "Using ActiveX Controls in IDL" in Chapter 5 of the *External Development Guide* manual.

## Superclasses

This class is a subclass of IDLcomIDispatch.

## Subclasses

When an ActiveX control is instantiated, IDL creates a dynamic subclass of the IDLcomActiveX class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See "ActiveX Control Naming Scheme" in Chapter 5 of the *External Development Guide* manual for details.

## Creation

IDLcomActiveX objects are always created automatically by IDL, as a result of a call to the WIDGET_ACTIVEX function. They should never be created manually.

## Properties

Objects of this class have no properties of their own.

## Methods

The IDLcomActiveX object class is a direct subclass of the IDLcomIDispatch class, and relies entirely on the superclass methods, providing none of its own.

## Version History

Introduced: 5.5

# IDLcomActiveX Properties

Objects of this class have no properties of their own.

# IDLcomIDispatch

The IDLcomIDispatch object class creates an IDL object that encapsulates a COM object. IDL provides data type and other translation services, allowing IDL programs to access the COM object's methods and properties using standard IDL syntax.

**Note**

COM objects encapsulated by IDLcomIDispatch objects must implement an IDispatch interface.

For detailed information on using the IDLcomIDispatch object, see Chapter 4, "Using COM Objects in IDL" in the *External Development Guide* manual.

## Superclasses

This class has no superclasses.

## Subclasses

When a COM object is instantiated, IDL creates a dynamic subclass of the IDLcomIDispatch class. The dynamic subclass is used to provide a unique name for each component type, based on the COM class or program identifier. See "IDLcomIDispatch Object Naming Scheme" in Chapter 4 of the *External Development Guide* manual for details.

ActiveX controls are instantiated within IDL as a special subclass of the IDLcomIDispatch class named IDLcomActiveX.

## Creation

See IDLcomIDispatch::Init

## Properties

Objects of this class have the following properties. See "IDLcomIDispatch Properties" on page 3757 for details on individual properties.

- *KEYWORD*

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

- IDLcomIDispatch::Init
- IDLcomIDispatch::GetProperty
- IDLcomIDispatch::SetProperty

In addition to these methods, you can call the underlying COM object's methods directly. See "Method Calls on IDLcomIDispatch Objects" in Chapter 4 of the *External Development Guide* manual for details.

**Note**

The IDL object system uses method names to identify and call object lifecycle methods (Init and Cleanup). If the COM object underlying an IDLcomIDispatch object implements Init or Cleanup methods, they will be overridden by IDL's lifecycle methods — the COM object's methods will be inaccessible from IDL. Similarly, IDL implements the GetProperty and SetProperty methods for the IDLcomIDispatch object, so any methods of the underlying COM object that use these names will be inaccessible from IDL.

## Version History

Introduced: 5.5

# IDLcomIDispatch Properties

IDLcomIDispatch objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Get” column of the property table can be retrieved via “IDLcomIDispatch::GetProperty” on page 3758. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via “IDLcomIDispatch::Init” on page 3759. Properties with the word “Yes” in the “Set” column in the property table can be set via “IDLcomIDispatch::SetProperty” on page 3760.

## *KEYWORD*

*KEYWORD* is a string containing the name of one of the underlying COM object’s properties, and *Variable* is the name of an IDL variable that will contain the retrieved property value. You can get multiple property values in a single statement by supplying multiple *KEYWORD=Variable* pairs.

**Note**

*KEYWORD* must map exactly to the full name of the underlying COM object’s property method. The partial keyword name functionality provided by IDL is not valid with IDLcomIDispatch objects.

# IDLcomIDispatch::GetProperty

The IDLcomIDispatch::GetProperty function method is used to get properties from the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the GetProperty method, and property values are treated as IDL keyword values. See "Managing COM Object Properties" in Chapter 4 of the *External Development Guide* manual.

## Syntax

*Obj* -> [IDLcomIDispatch::]GetProperty, *KEYWORD=Variable*, [*arg0*, *arg1*, …]

## Arguments

Because some of the underlying COM object's property methods may require arguments, the GetProperty method will accept optional arguments. The values of the arguments themselves will depend on the COM object that underlies the IDLcomIDispatch object.

**Note**

If arguments are required, you can only specify one property to retrieve in a given call to the GetProperty method.

## Keywords

Any property listed under "IDLcomIDispatch Properties" on page 3757 that contains the word "Yes" in the "Get" column of the properties table can be retrieved using this method. To retrieve the value of a property, specify the property name as a keyword set equal to a named variable that will contain the value of the property.

## Version History

Introduced: 5.5

# IDLcomIDispatch::Init

The IDLcomIDispatch::Init function method is used to initialize a given COM object and establish a link between the resulting IDL object and the IDispatch interface of the underlying COM object.

## Syntax

*Obj* = OBJ_NEW('IDLcomIDispatch$*ID_type*$*ID*')

or

*Result* = *Obj* `->` [IDLcomIDispatch$*ID_type*$*ID*::]Init( ) (*Only in a subclass' Init method*)

where *ID_type* is one of the following:

- `CLSID` if the object is identified by its COM class ID, or
- `PROGID` if the object is identified by its COM program ID,

and *ID* is the COM object's actual class or program identifier string. If the COM object's class identifier string is used to create the IDLcomIDispatch object, the braces ( { } ) must be removed and the hyphens replaced by underscores. For details on constructing the class name, see "IDLcomIDispatch Object Naming Scheme" in Chapter 4 of the *External Development Guide* manual for details.

**Note**

While COM objects incorporated into IDL are instances of the dynamic subclass created when the COM object is instantiated, they still expose the functionality of the class IDLcomIDispatch, which is the direct superclass of the dynamic subclass. All IDLcomIDispatch methods are available to the dynamic subclass.

## Arguments

None.

## Keywords

None.

## Version History

Introduced: 5.5

# IDLcomIDispatch::SetProperty

The IDLcomIDispatch::SetProperty function method is used to set properties for the COM object that underlies an IDLcomIDispatch object. The COM object's property names are represented as IDL keywords to the SetProperty method, and property values are treated as IDL keyword values. See "Managing COM Object Properties" in Chapter 4 of the *External Development Guide* manual for details.

## Syntax

*Obj* -> [IDLcomIDispatch::]SetProperty, *KEYWORD=Expression*

## Arguments

None.

## Keywords

Any property listed under "IDLcomIDispatch Properties" on page 3757 that contains the word "Yes" in the "Set" column of the properties table can be set using this method. To set the value of a property, specify the property name as a keyword set equal to the appropriate property value.

## Version History

Introduced: 5.5

# IDLjavaObject

The IDLjavaObject class creates an IDL object that encapsulates a Java object. IDL provides data type and other translation services, allowing IDL programs to access the Java object's methods and properties using standard IDL syntax.

For detailed information on using the IDLjavaObject class, see Chapter 8, "Using Java Objects in IDL" in the *External Development Guide* manual.

## Superclasses

This class has no superclasses.

## Creation

See "IDLjavaObject::Init" on page 3765.

## Properties

The properties of this object depends on which Java object the IDLjavaObject class encapsulates. See "IDLjavaObject Properties" on page 3763 for more details.

## Methods

This class has the following methods:

- IDLjavaObject::GetProperty
- IDLjavaObject::Init
- IDLjavaObject::SetProperty

In addition to these methods, you can call the underlying Java object's methods directly. See "Method Calls on IDL-Java Objects" in Chapter 8 of the *External Development Guide* manual for details.

**Note**

The IDL object system uses method names to identify and call object *lifecycle methods* (Init and Cleanup). If the Java object underlying IDLjavaObject implements Init or Cleanup methods, they will be overridden by IDL's lifecycle methods — the Java object's methods will be inaccessible from IDL. Similarly, IDL implements the GetProperty and SetProperty methods for IDLjavaObject, so any methods of the underlying Java object that use these names will be inaccessible

from IDL. In Java, you can wrap these methods with different named methods to work around this limitation.

## Examples

See Chapter 8, “Using Java Objects in IDL” in the *External Development Guide* manual.

## Version History

Introduced: 6.0

# IDLjavaObject Properties

The property name of an instance of IDLjavaObject is passed to the IDL Java subsystem and is used in conjunction with the Java reflection API to access the related data member on the underlying object. The data member (property) is identified through the arguments to the IDLjavaObject::GetProperty and IDLjavaObject::SetProperty methods.

# IDLjavaObject::GetProperty

The IDLjavaObject::GetProperty procedure method retrieves properties (known as data members in Java) from the Java object that underlies the IDLjavaObject. The Java object's property names are represented as IDL keywords to the GetProperty method, and property values are treated as IDL keyword values. See "Managing IDL-Java Object Properties" in Chapter 8 of the *External Development Guide* manual.

## Syntax

*Obj* -> [IDLjavaObject::]GetProperty [, *PROPERTY=variable*]

## Arguments

None

## Keywords

### *PROPERTY*

The Java object property names are mapped to IDL keywords. The underlying property values are treated as IDL keyword values, which is the same convention for other IDL objects.

**Note**

The provided keywords must map directly to a property name or IDL issues an error. Any keyword passed into either of the property routines is assumed to be a fully-qualified Java property name. As such, the partial keyword name functionality provided by IDL is not valid with IDL Java based objects.

The *variable* may be an IDL primitive type, an instance of IDLJavaObject, or an array of IDL primitive types. See "IDL-Java Bridge Data Type Mapping" in Chapter 8 of the *External Development Guide* manual for more information.

**Note**

Besides other Java based objects, no complex types (structures, pointers, etc.) are supported as parameters to method calls.

## Version History

Introduced: 6.0

# IDLjavaObject::Init

The IDLjavaObject::Init function method instantiates the given Java object and establishes a link between the resulting IDL object with the underlying Java object.

**Note**

Init methods are special *lifecycle methods*, and as such cannot be called outside the context of object creation. This means that in most cases, you cannot call the Init method directly. There is one exception to this rule: the Init method can be called from within the Init method of a subclass.

## Syntax

*Obj* = OBJ_NEW('IDLjavaObject$*JAVACLASSNAME*', *JavaClassName*[, *Arg1*, ...])

where *JAVACLASSNAME* is a case-insensitive string representing the Java class to be instantiated, see "IDL-Java Bridge Architecture" in Chapter 8 of the *External Development Guide* manual for more information. All periods in *JAVACLASSNAME* must be converted to underscores.

## Return Value

Returns an object reference to the newly-created object if initialization is successful, or a null object if initialization fails.

## Arguments

### JavaClassName

A string representing the Java class to be instantiated. See "Java Class Names in IDL" in Chapter 8 of the *External Development Guide* manual for more details.

### Arg1, ...

Additional arguments as required by the contructor. These arguments are passed to the underlying Java constructor. Arguments may be IDL primitive types, IDL strings, IDLJavaObjects, and arrays of the previous types. See "IDL-Java Bridge Data Type Mapping" in Chapter 8 of the *External Development Guide* manual for more information.

## Keywords

None

## Version History

Introduced: 6.0

# IDLjavaObject::SetProperty

The IDLjavaObject::SetProperty procedure method sets properties (known as data members in Java) for the Java object that underlies an instance of IDLjavaObject. The Java object's property names are represented as IDL keywords to the SetProperty method, and property values are treated as IDL keyword values. See "Managing IDL-Java Object Properties" in Chapter 8 of the *External Development Guide* manual for more details.

## Syntax

*Obj* -> [IDLjavaObject::]SetProperty [, *PROPERTY=value*]

## Arguments

None

## Keywords

### *PROPERTY*

The Java object property names are mapped to IDL keywords. The underlying property values are treated as IDL keyword values, which is the same convention for other IDL objects.

**Note**

The provided keywords must map directly to a property name or IDL issues an error. Any keyword passed into either of the property routines is assumed to be a fully-qualified Java property name. As such, the partial keyword name functionality provided by IDL is not valid with IDL Java based objects.

The *value* may be an IDL primitive type, an instance of IDLJavaObject, or an array of IDL primitive types. See "IDL-Java Bridge Data Type Mapping" in Chapter 8 of the *External Development Guide* manual for more information.

**Note**

Besides other Java based objects, no complex types (structures, pointers, etc.) are supported as parameters to method calls.

## Version History

Introduced: 6.0

# TrackBall

A TrackBall object translates widget events from a draw widget (created with the WIDGET_DRAW function) into transformations that emulate a virtual trackball (for transforming object graphics in three dimensions).

This object class is implemented in the IDL language. Its source code can be found in the file `trackball__define.pro` in the `lib` subdirectory of the IDL distribution.

## Superclasses

This class has no superclasses.

## Creation

See "TrackBall::Init" on page 3772.

## Properties

Objects of this class have the following properties. See "TrackBall Properties" on page 3770 for details on individual properties.

- AXIS
- CONSTRAIN
- MOUSE

In addition, objects of this class inherit the properties of all superclasses of this class.

## Methods

This class has the following methods:

- TrackBall::Init
- TrackBall::Reset
- TrackBall::Update

In addition, this class inherits the methods of its superclasses (if any).

## Version History

Introduced: 5.0

# TrackBall Properties

TrackBall objects have the following properties in addition to properties inherited from any superclasses. Properties with the word “Yes” in the “Init” column of the property table can be retrieved via “TrackBall::Init” on page 3772.

**Note**

For a discussion of the property description tables shown below, see “About Object Property Descriptions” on page 2505.

## AXIS

An integer value that indicates the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the *X* axis.
- 1 = Rotate only around the *Y* axis.
- 2 = Rotate only around the *Z* axis (this is the default).

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## CONSTRAIN

A boolean value that indicates whether the trackball transformations are to be constrained about the axis specified by the AXIS keyword. The default is not to constrain the transformations.

| **Property Type** | Boolean | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

## MOUSE

An integer value that indicates which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)

- 2 = Middle mouse button
- 4 = Right mouse button

| **Property Type** | Integer | | |
|---|---|---|---|
| **Name String** | *not displayed* | | |
| **Get:** No | **Set:** No | **Init:** Yes | **Registered:** No |

# TrackBall::Init

The TrackBall::Init function method initializes the TrackBall object.

# Syntax

*Obj* = OBJ_NEW('TrackBall', *Center*, *Radius* [, AXIS={0 | 1 | 2}] [, /CONSTRAIN] [, MOUSE={1 | 2 | 4}] )

or

*Result* = *Obj* -> [TrackBall::]Init( *Center*, *Radius* ) (*Only in a subclass' Init method*.)

**Note**

Keywords can be used in either form. They are omitted in the second form for brevity.

# Arguments

## Center

A two-element vector, [*X*, *Y*], specifying the center coordinates of the trackball. *X* and *Y* should be specified in device units.

## Radius

The radius of the trackball, specified in device units.

# Keywords

Any property listed under "TrackBall Properties" on page 3770 that contains the word "Yes" in the "Init" column of the properties table can be initialized during object creation using this method. To initialize the value of a property, specify the property name as a keyword set equal to the appropriate property value.

# Version History

Introduced: 5.0

# TrackBall::Reset

The TrackBall::Reset procedure method resets the state of the TrackBall object.

# Syntax

*Obj* -> [TrackBall::]Reset, *Center*, *Radius* [, AXIS={0 | 1 | 2}] [, /CONSTRAIN] [, MOUSE={1 | 2 | 4}]

# Arguments

## Center

A two-element vector, [*X*, *Y*], specifying the center coordinates of the trackball. *X* and *Y* should be specified in device units.

## Radius

The radius of the trackball, specified in device units.

# Keywords

## AXIS

Set this keyword to an integer value to indicate the axis about which rotations are to be constrained if the CONSTRAIN keyword is set. Valid values include:

- 0 = Rotate only around the *X* axis.
- 1 = Rotate only around the *Y* axis.s
- 2 = Rotate only around the *Z* axis (this is the default).

## CONSTRAIN

Set this keyword to indicate that the trackball transformations are to be constrained about the axis specified by the AXIS keyword. The default is not to constrain the transformations.

### MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

## Version History

Introduced: 5.0

# TrackBall::Update

The TrackBall::Update function method updates the state of the TrackBall object based on the information contained in the input widget event structure. The return value is nonzero if a transformation matrix is calculated as a result of the event, or zero otherwise.

# Syntax

*Result* = *Obj* -> [TrackBall::]Update( *sEvent* [, MOUSE={1 | 2 | 4}] [, TRANSFORM=*variable*] [, /TRANSLATE] )

# Arguments

## sEvent

The widget event structure.

# Keywords

## MOUSE

Set this keyword to an integer value to indicate which mouse button to honor for trackball events. Valid values include:

- 1 = Left mouse button (the default)
- 2 = Middle mouse button
- 4 = Right mouse button

## TRANSFORM

Set this keyword to a named variable that will contain a 4 x 4 element floating-point array if a new transformations matrix is calculated as a result of the widget event.

## TRANSLATE

Set this keyword to indicate that the trackball movement should be constrained to translation in the *X*-*Y* plane rather than rotation about an axis.

# Example

The example code below provides a skeleton for a widget-based application that uses the TrackBall object to interactively change the orientation of graphics.

Create a trackball centered on a 512x512 pixel drawable area, and a view containing the model to be manipulated:

```
xdim = 512
ydim = 512
wBase = WIDGET_BASE()
wDraw = WIDGET_DRAW(wBase, XSIZE=xdim, YSIZE=ydim, $
    GRAPHICS_LEVEL=2, /BUTTON_EVENTS, $
    /MOTION_EVENTS, /EXPOSE_EVENTS, RETAIN=0 )
WIDGET_CONTROL, wBase, /REALIZE
WIDGET_CONTROL, wDraw, GET_VALUE=oWindow

oTrackball = OBJ_NEW('Trackball', [xdim/2.,ydim/2.], xdim/2.)
oView = OBJ_NEW('IDLgrView')
oModel = OBJ_NEW('IDLgrModel')
oView->Add, oModel
XMANAGER, 'TrackEx', wBase
```

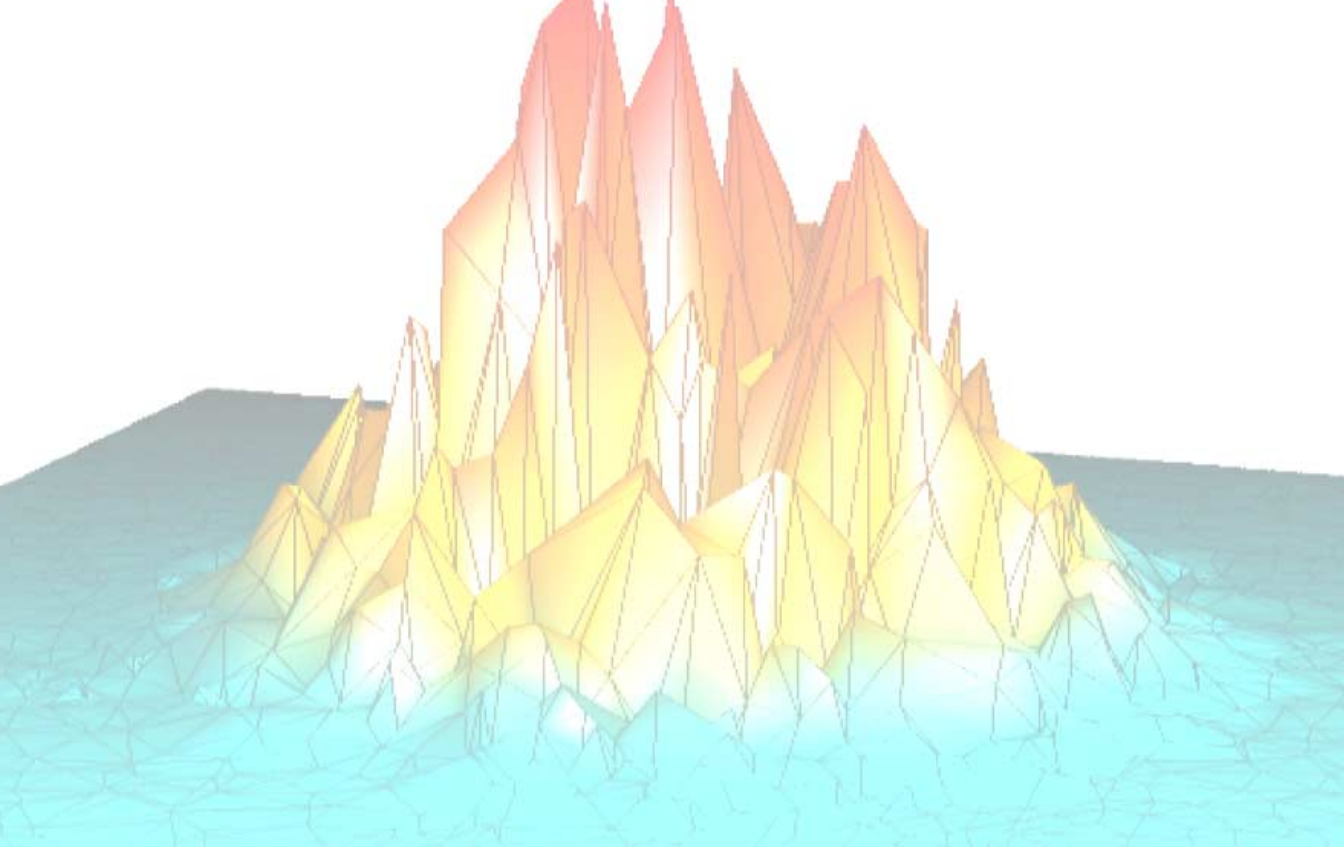
You must handle the trackball updates in the widget event-handling code. As the trackball transformation changes, update the transformation for the model object, and redraw the view:

```
PRO TrackEx_Event, sEvent
...
bHaveXform = oTrackball->Update( sEvent, TRANSFORM=TrackXform )
IF (bHaveXform) THEN BEGIN
oModel->GetProperty, TRANSFORM=ModelXform
oModel->SetProperty, TRANSFORM=ModelXform # TrackXform
oWindow->Draw, oView
ENDIF
...
END
```

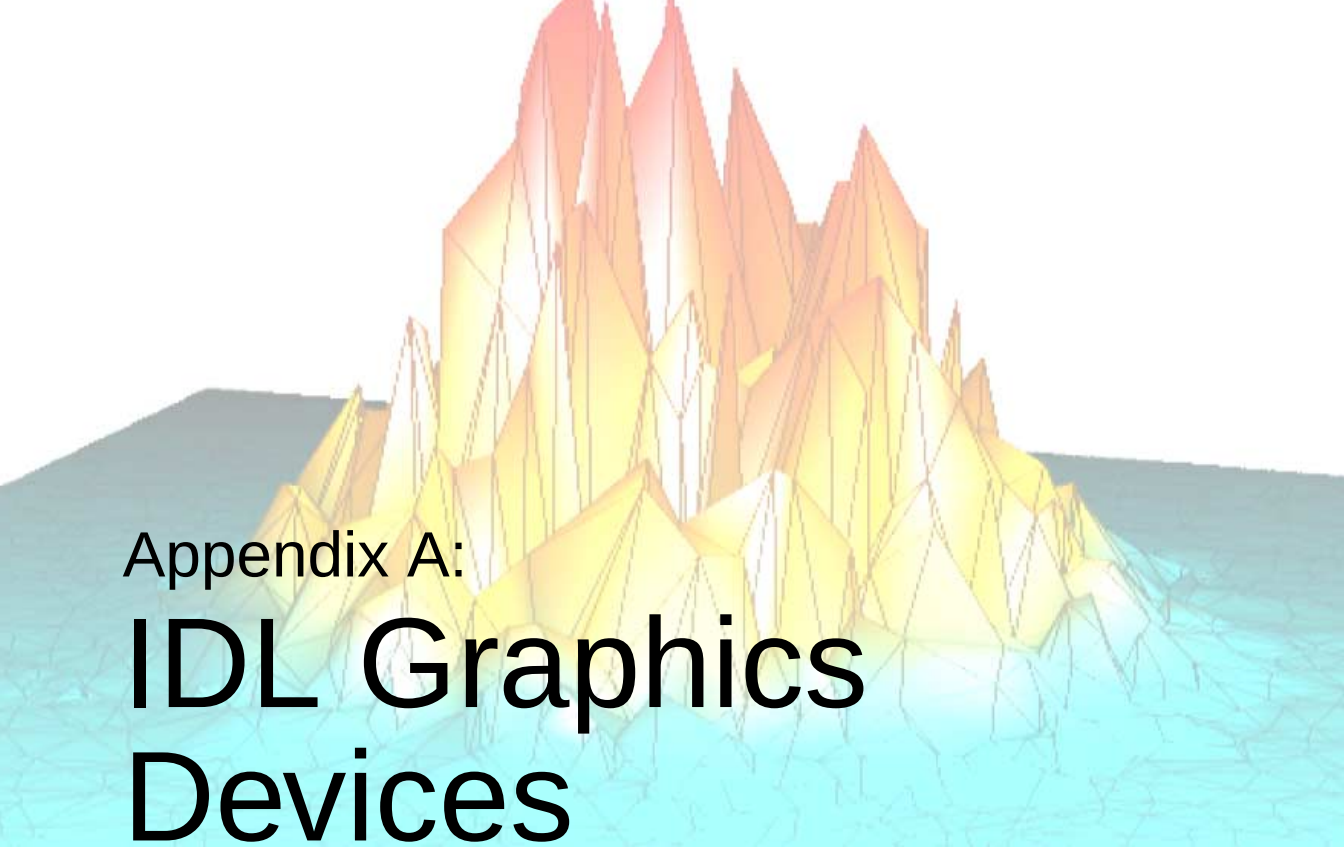
For a complete example, see the file `surf_track.pro`, located in the `examples/visual` subdirectory of the IDL distribution. The SURF_TRACK procedure uses IDL widgets to create a graphical user interface to an object tree, creates a surface object from user-specified data (or from default data, if none is specified), and places the surface object in an IDL draw widget. The SURF_TRACK interface allows the user to specify several attributes of the object hierarchy via pulldown menus.

## Version History

Introduced: 5.0



# *Part III: Appendices*



# Appendix A: IDL Graphics Devices

The following topics are covered in this appendix:

# Supported Devices

IDL Direct Graphics support graphic output to the devices listed below:

| Device Name | Description |
|---|---|
| CGM | Computer Graphics Metafile |
| HP | Hewlett-Packard Graphics Language (HP-GL) |
| METAFILE | Windows Metafile Format (WMF) |
| NULL | No graphics output |
| PCL | Hewlett-Packard Printer Control Language (PCL) |
| PRINTER | System printer |
| PS | PostScript |
| REGIS | Regis graphics protocol (DEC systems only) |
| TEK | Tektronix compatible terminal |
| WIN | Microsoft Windows |
| X | X Window System |
| Z | Z-buffer pseudo device |

*Table A-1: IDL Graphics Output Devices*

Each of these devices is described in a section of this chapter. The SET_PLOT procedure can be used to select the graphic device to which IDL directs its output. IDL Object Graphics does not rely on the concept of a current graphics device; see *Using IDL* for details about IDL Object Graphics.

The DEVICE procedure controls the graphic device-specific functions. An attempt has been made to isolate all device-specific functions in this procedure. DEVICE controls the graphics device currently selected by SET_PLOT. When using DEVICE, it is important to make sure that the current graphics device is the one you intend to use. This is because most of the devices have different keywords—you will most likely get a ‘‘`Keyword ... ... not allowed in call to: Device`’’ error if you call DEVICE when the wrong device is selected.

# Obsolete Graphics Devices and Device Keywords

The following graphics devices are obsolete:

- LJ
- MAC

For information on obsolete graphics devices, See Appendix I, “Obsolete Features”.

The following graphics device keywords are obsolete:

- DEPTH
- FONT

For information on obsolete keywords, See Appendix I, “Obsolete Features”.

# Keywords Accepted by the IDL Devices

The following table indicates which keywords are accepted by the DEVICE procedure. The NULL device is not listed as it accepts no keywords. Details of the various keywords can be found on the page indicated in the table.

**Note**

Most keywords to the DEVICE procedure are sticky — that is, once you set them, they remain in effect until you explicitly change them again, or end your IDL session. The exceptions are keywords used to return a value from the system (GET_FONTNAMES, for example) and those that perform a one-time-only operation (CLOSE_FILE, for example).

| Keywords | Devices | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | CGM | HP | METAFILE | PCL | PRINTER | PS | REGIS | TEK | WIN | X | Z |
| AVANTGARDE | | | | | | • | | | | | |
| AVERAGE_LINES | | | | | | | • | | | | |
| BINARY | • | | | | | | | | | | |
| BITS_PER_PIXEL | | | | | | • | | | | | |
| BKMAN | | | | | | • | | | | | |
| BOLD | | | | | | • | | | | | |
| BOOK | | | | | | • | | | | | |
| BYPASS_TRANSLATION | | | | | | | | | • | • | |
| CLOSE | | | | | | | | | | | • |
| CLOSE_DOCUMENT | | | | | • | | | | | | |
| CLOSE_FILE | • | • | • | • | | • | • | • | | | |

*Table A-2: Keywords accepted by the IDL devices*

*Table A-2: Keywords accepted by the IDL devices (Continued)*

Keywords accepted by the DEVICE command are described below. A list of devices that accept the keyword is included in parentheses below the keyword name.

## AVANTGARDE

(PS)

Set this keyword to select the ITC Avant Garde PostScript font.

## AVERAGE_LINES

(REGIS)

Controls the method of writing images to the VT240. If this keyword is set, (default setting), even and odd pairs of image lines are averaged and written to a single line. If clear, each image line is written to the screen. See the discussion below. This keyword has no effect when using a VT300 series terminal.

## BINARY

(CGM)

Set this keyword to set the encoding type for the CGM output file to binary.

## BITS_PER_PIXEL

(PS)

IDL is capable of producing PostScript images with 1, 2, 4, or 8 bits per pixel. Using more bits per pixel gives higher resolution at the cost of generating larger files. BITS_PER_PIXEL is used to specify the number of bits to use. If you do not specify a value for BITS_PER_PIXEL, a default value of 4 is used.

It should be noted that many laser printers, including the original Apple Laserwriter are capable of only 32 different shades of gray (which can be represented by 5 bits). Thus, specifying 8 bits per pixel does not give 256 apparent shades of grey as might be expected, only 32, at a cost of sending twice the number of bits to the printer. Often, 4 bits (16 levels of gray) will give acceptable results with a large savings in file size.

## BKMAN

(PS)

Set this keyword to select the ITC Bookman PostScript font.

## BOLD

(PS)

Set this keyword to specify that the bold version of the current PostScript font should be used.

## BOOK

(PS)

Set this keyword to specify that the book version of the current PostScript font should be used.

## BYPASS_TRANSLATION

(WIN, X)

Set this keyword to bypass the translation tables, allowing direct specification of color indices. See “Color Translation” on page 3861 Pixel values read via the TVRD function are not translated if this keyword is set, and the result contains the byte value of the actual pixel values present in the display.

By default, the translation tables are used with shared and static color tables. When using displays with private color tables, the translation tables are bypassed.

This keyword is accepted by the WIN device (for compatibility with the X device), but has no effect when set.

## CLOSE

(Z)

Set this keyword to deallocate the memory used by the Z-buffer. The Z-buffer device is reinitialized if subsequent graphics operations are directed to the device.

## CLOSE_DOCUMENT

(PRINTER)

Set this keyword to have IDL send any buffered output to the currently selected printer. This keyword is applicable only when the printer device is selected. See “The Printer Device” on page 3839 for details.

## CLOSE_FILE

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Set this keyword to have IDL output any buffered commands and close the current graphics file.

Caution: If you close the output file and then cause IDL to produce more output (e.g., by executing a new PLOT command), IDL will open the file again, causing the contents of the recently closed file to be lost. To avoid this, use the FILENAME keyword to specify a different file name or use SET_PLOT to disable the graphics driver, or be sure to print the closed output file before creating more output.

See the discussion of printing output files in “Printing Graphics Output Files” on page 3827

## COLOR

(PCL, PS)

Set this keyword to enable color PCL or PostScript output. See "The PCL Device" on page 3837 or "The PostScript Device" on page 3840.

## COLORS

(CGM, TEK)

This keyword specifies the maximum number of colors and the size of the color table used for output. The value of the system variable fields !D.N_COLORS and !D.TABLE_SIZE are set to this value and !P.COLOR is set to one less than this value.

### For Tektronix Terminals Only

This keyword sets the number of colors supported by a 4100 series terminal. For example, if your terminal has 4-bit planes, the number of colors is $2^4 = 16$:

```
DEVICE, COLORS = 16
```

Valid values of this parameter are: 2, 4, 8, 16, or 64; other values will cause problems. Some Tektronix terminals will not operate properly if this parameter does not exactly match the number of colors available in the terminal hardware.

This parameter sets the field !D.N_COLORS, which affects the loading of color tables, the scaling used by the TVSCL procedure, and the number of bits output by the TV procedure to the terminal. It also changes the default color, !P.COLOR to the number of colors minus one.

## COPY

(WIN, X)

Use this keyword to copy a rectangular area of pixels from one region of a window to another. COPY should be set a six or seven element array: $[X_s, Y_s, N_x, N_y, X_d, Y_d, W]$, where: $(X_s, Y_s)$ is the lower left corner of the source rectangle, $(N_x, N_y)$ are the number of columns and rows in the rectangle, and $(X_d, Y_d)$ is the coordinate of the destination rectangle. Optionally, $W$ is the index of the window *from which the pixels should be copied to the current* window. If it is not supplied, the current window is used as both the source and destination.

## COURIER

(PS)

Set this keyword to select the Courier PostScript font.

## CURSOR_CROSSHAIR

(WIN, X)

Set this keyword to selects the crosshair cursor type. This is the IDL default.

## CURSOR_IMAGE

(WIN, X)

Specifies the cursor pattern. The value of this keyword must be a 16-line by 16-column bitmap, contained in a 16-element short integer vector. The offset from the upper left pixel to the point that is considered the hot spot can be provided via the CURSOR_XY keyword.

## CURSOR_MASK

(WIN, X)

When the CURSOR_IMAGE keyword is used to specify a cursor bitmap, the CURSOR_MASK keyword can be used to simultaneously specify the mask that should be used. In the mask, bits that are set indicate bits in the CURSOR_IMAGE that should be seen and bits that are not set are masked out.

By default, the CURSOR_IMAGE bitmap is used for both the image and the mask. This can cause the cursor to be invisible on a black background (because only black pixels are allowed to be displayed).

## CURSOR_ORIGINAL

(WIN, X)

Set this keyword to select the window system’s default cursor. Under X Windows, it is the cursor in use by the root window when IDL starts. For the Microsoft Windows device, it is the arrow pointer.

## CURSOR_STANDARD

(WIN, X)

This keyword can be used to change the cursor appearance in IDL graphics windows.

### For X Windows

This keyword selects one of the predefined cursors provided by the X Window system. The available cursors shapes are defined in the file `cursorfont.h` in the directory `/usr/include/X11`. In order to use one of these cursors, you select the number of the cursor and provide it as the value of the CURSOR_STANDARD keyword. For example, the file gives the value of XC_CROSS as being 30. In order to make that the current cursor, use the statement:

```
DEVICE, CURSOR_STANDARD=30
```

### For Microsoft Windows

The table below shows the values for CURSOR_STANDARD that result in different cursor shapes. For example, to change the cursor to an “I-beam” when the cursor is in an IDL graphics window, use the command:

```
DEVICE, CURSOR_STANDARD = 32513
```

| Value | Cursor Shape |
|---|---|
| 32512 | Arrow |
| 32513 | I-Beam |
| 32514 | Hourglass |
| 32515 | Black Crosshair |
| 32516 | Up Arrow |
| 32640 | Size (Windows NT only) |
| 32641 | Icon (Windows NT only) |
| 32642 | Size NW-SE |
| 32643 | Size NE-SW |
| 32644 | Size E-W |
| 32645 | Size N-S |

*Table A-3: Values for the WIN device CURSOR_STANDARD Keyword*

## CURSOR_XY

(WIN, X)

A two element integer vector giving the (X, Y) pixel offset of the cursor hot spot, the point which is considered to be the mouse position, from the lower left corner of the cursor image. This parameter is only applicable if CURSOR_IMAGE is provided. The cursor image is displayed top-down—the first row is displayed at the top.

## DECOMPOSED

(WIN, X)

This keyword is used to control the way in which graphics color index values are interpreted when using displays with decomposed color (TrueColor or DirectColor visuals). This keyword has no effect with other types of visuals.

Set this keyword to 1 to cause color indices to be interpreted as 3, 8-bit color indices where the least-significant 8 bits contain the red value, the next 8 bits contain the green value, and the most-significant 8 bits contain the blue value. This is the way IDL has always interpreted pixels when using visual classes with decomposed color.

Set this keyword to 0 to cause the least-significant 8 bits of the color index value to be interpreted as a PseudoColor index. This setting allows users with DirectColor and TrueColor displays to use IDL programs written for standard, PseudoColor displays without modification.

In older versions of IDL, color index values higher than !D.N_COLORS-1 were clipped to !D.N_COLORS-1 in the higher level graphics routines. In some cases, this clipping caused the exclusive-OR graphics mode to malfunction with raster displays. This clipping has been removed. Programs that incorrectly specified color indices higher than !D.N_COLORS-1 will now probably exhibit different behavior.

## DEMI

(PS)

Set this keyword to specify that the demi version of the current PostScript font should be used.

## DIRECT_COLOR

(X)

Set this keyword to select the DirectColor visual. The value of the keyword represents the number of bits per pixel. This keyword has effect only if no windows have been

created. Visual classes are discussed in more detail in “X Windows Visuals” on page 3856.

## EJECT

(HP)

In order to perform an erase operation on a plotter, it is necessary to remove the current sheet of paper and load a fresh sheet. The ability of various plotters to do this varies, so the EJECT keyword allows you to specify what should be done. The following table describes the possible values.

| Value | Meaning |
|---|---|
| 0 | Do nothing. Note that this is likely to cause one page to plot over the previous one, so you should limit yourself to one page of output per file. This is the default. |
| 1 | Use the sheet feeder to load the next page. |
| 2 | Put the plotter off-line at the beginning of each page after the first. |

*Table A-4: Values for the HP-GL Eject Keyword*

Many HP-GL plotters lack a sheet feeder, and require the user to load the next page manually. Therefore, the default action is for IDL to not issue any page eject instructions. In this case, you must restrict yourself to generating only a single plot at a time. If your plotter has a sheet feeder, you will want to issue the command:

```
DEVICE, /EJECT
```

to tell IDL that it should use the sheet feeder instead of placing the plotter off-line.

If your plotter does not have a sheet feeder, but it does understand the HP-GL NR command, use the command:

```
DEVICE, EJECT=2
```

to place the plotter off-line at the start of every plot except the first one. This causes the plotter to wait between plots for the user to replace the paper. When the user puts the plotter back on-line, the graphics commands for the new page are executed by the plotter. Consult the programming manual for your plotter to determine if this instruction is provided.

## ENCAPSULATED

(PS)

Set this keyword to create an encapsulated PostScript file, suitable for importing into another document (e.g., a LaTeX or FrameMaker document).

**Note**

You must explicitly set this keyword to zero to create “regular” PostScript output after creating encapsulated output. (That is, like most keyword settings to the DEVICE procedure, the setting “sticks” until you change it, or until you quit IDL.)

Normally, IDL assumes that its PostScript-generated output will be sent directly to a printer. It therefore includes PostScript commands to position the plot on the page and to eject the page from the printer. These commands are undesirable if the output is going to be inserted into the middle of another PostScript document. If ENCAPSULATED is present and non-zero, IDL does not generate these commands.

IDL follows the standard PostScript convention for encapsulated files. It assumes the standard PostScript scaling is in effect (72 points per inch), In addition, it declares the size, or *bounding box* of the plotting region at the top of the output file. This size is determined when the output file is opened (when the first graphics command is given), by multiplying the size of the plotting region (as specified with the XSIZE and YSIZE keywords) by the current scale factor (as specified by the SCALE_FACTOR keyword).

Changing the size of the plotting region or scale factor once graphics have been output will not be reflected in the declared bounding box, and will confuse programs that attempt to import the resulting graphics. Therefore, when generating encapsulated PostScript, do not change the plot region size or scaling factor once any graphics commands have been issued. If you need to change these parameters, use the FILENAME keyword to start a new file.

## ENCODING

(CGM)

Set this keyword to set the CGM encoding type for the output file. Valid values are:

| Value | Description |
|---|---|
| 1 | Binary encoding - the default. |

*Table A-5: CGM Encoding Values*

| Value | Description |
|---|---|
| 2 | Text encoding. |
| 3 | NCAR binary encoding. |

*Table A-5: CGM Encoding Values*

The encoding type can only be changed when no CGM file is open.

## FILENAME

(CGM, HP, METAFILE, PCL, PS, REGIS, TEK)

Normally, all generated output is sent to a file named `idl.xxx`, where `xxx` is the lowercase name of the device shown in the table under "Supported Devices" on page 3782. The FILENAME keyword can be used to change these defaults. If FILENAME is specified:

1. If the file is already open (as happens if plotting commands have been directed to the file since the call to SET_PLOT), then the file is completed and closed as if CLOSE_FILE had been specified.
2. The specified file is opened for subsequent graphics output.

### HP-GL Only

Under UNIX, if you wish to send HP-GL output directly to a plotter without generating an intermediate file, you should specify the device special file for the plotter as the argument to FILENAME. For example, if your plotter is connected to a serial input/output port known on your system as `/dev/ttya`, you would issue the command:

```
DEVICE, FILENAME='/dev/ttya'
```

All subsequent HP-GL output is sent directly to the plotter connected to serial port `/dev/ttya`.

## FLOYD

(PCL, X)

Set this keyword to select the Floyd-Steinberg method of dithering. This algorithm distributes the error, due to displaying intermediate shades in either black or white, to surrounding pixels. This method generally gives the most pleasing results but requires the most computer time.

## FONT_INDEX

(PS)

An integer representing the font index to be mapped to the current PostScript font.

Normally the font specification keywords (AVANTGARDE, etc.) take effect immediately to change the current font. The FONT_INDEX keyword alters this behavior. The current font is not changed. Instead, the specified font is mapped to the specified font index. This mapping can then be used within text strings to change the font in the middle of the string. See “Using PostScript Fonts” on page 3841

## FONT_SIZE

(PS)

The default height used for displayed text. FONT_SIZE is given in points (a common typesetting unit of measure). The default size is 12 point text.

## GET_CURRENT_FONT

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the name of the current font is returned as a scalar string. A null string is returned if the Windows font is the default font. If the current device is PRINTER or METAFILE, the current font is returned.

## GET_DECOMPOSED

(WIN, X)

Set this keyword to a named variable in which is returned the current state of the decomposed flag in the current direct graphics device.

## GET_FONTNAMES

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which a string array containing the names of available fonts is returned. If no fonts are found, a null scalar string is returned. This keyword must be used in conjunction with the SET_FONT keyword. Set the SET_FONT keyword to a scalar string containing the name of the desired font or to a wildcard. For example, the following command will return in the variable `fnames` the names of all available fonts:

```
DEVICE, GET_FONTNAMES=fnames, SET_FONT='*'
```

## GET_FONTNUM

(METAFILE, PRINTER, WIN, X)

Set this keyword to a named variable in which the number of fonts available to your installation is returned. This keyword must be used in conjunction with the SET_FONT keyword. Set the SET_FONT keyword to a scalar string containing the name of the desired font or a wildcard. For example, the following command will return in the variable `numfonts` the number of available fonts:

```
DEVICE, GET_FONTNUM=numfonts, SET_FONT='*'
```

## GET_GRAPHICS_FUNCTION

(WIN, X, Z)

Set this keyword to a named variable that returns the value of the current graphics function (which is set with the SET_GRAPHICS_FUNCTION keyword). This can be used to remember the current graphics function, change it temporarily, and then restore it. See “SET_GRAPHICS_FUNCTION” on page 3815 keyword for an example.

## GET_PAGE_SIZE

(PRINTER)

Set this keyword to a named variable in which to return a two-element vector that contains the width and height of the page size in pixels.

## GET_SCREEN_SIZE

(WIN, X)

Set this keyword to a named variable in which to return a two-word array that contains the width and height of the server’s screen, in pixels.

## GET_VISUAL_DEPTH

(WIN, X)

Set this keyword to a named variable into which a long integer is returned containing the depth of the visual associated with this device. Under X, if the X server is not connected when you call the DEVICE procedure with this keyword set, a new connection is made.

## GET_VISUAL_NAME

(WIN, X)

Set this keyword equal to a named variable in which a string containing the name of the current visual class IDL is using is returned. Possible return values are:

- StaticGray (X only)
- GrayScale (X only)
- StaticColor (X only)
- PseudoColor
- TrueColor
- DirectColor (X only)

Under X, if no connection to the X server has been established when the DEVICE procedure is called with this keyword set, a new connection is made.

## GET_WINDOW_POSITION

(WIN, X)

Set this keyword to a named variable that returns a two-element array containing the (X,Y) position of the lower left corner of the current window on the screen. The origin is also in the lower left corner of the screen.

## GET_WRITE_MASK

(WIN, X)

Specifies the name of a variable to receive the current value of the write mask.

## GIN_CHARS

(TEK)

The number of characters IDL is to read when accepting a GIN (Graphics INput) report. The default is 5. If your terminal is configured to send a carriage return at the end of each GIN report, set this parameter to 6. If the number of GIN characters is too large, the IDL CURSOR procedure will not respond until two or more keys are struck. If it is too small, the extra characters sent by the terminal will appear as input to the next IDL prompt.

## GLYPH_CACHE

(METAFILE, PRINTER, PS, WIN, Z)

Set this keyword to a scalar specifying the maximum number of glyphs to cache at any given time. The first time a glyph from a TrueType font is used, it is tessellated into triangles. These triangles are cached so that the tessellation step is not repeated for each use of that glyph. If the glyph cache fills, the least used glyph will be released before a new glyph is generated and cached. The default is 256.

## HELVETICA

(PS)

Set this keyword to select the Helvetica PostScript font.

## INCHES

(HP, METAFILE, PCL, PRINTER, PS)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if INCHES is present and non-zero, they are taken to be in inches instead.

## INDEX_COLOR

(METAFILE, PRINTER)

Set this keyword to place the printer or MetaFile device in index color mode. This is the default. This keyword is applicable only when the printer or MetaFile device is selected.

## ISOLATIN1

(PS)

Set this keyword to use Adobe ISO Latin 1 font encoding with any font that supports such coding. Use of this keyword allows access to many commonly-used foreign characters.

## ITALIC

(PS)

Set this keyword to specify that the italic version of the current PostScript font should be used.

## LANDSCAPE

(HP, PCL, PRINTER, PS)

IDL normally generates plots with portrait orientation (the abscissa is along the short dimension of the page). If the LANDSCAPE keyword is set, landscape orientation (abscissa along the long dimension of the page) is used instead. Note that explicitly setting LANDSCAPE=0 is the same as setting the PORTRAIT keyword.

If the current device is PRINTER, and a page is open in the printer, it is closed and a new page set to landscape layout is started.

**Note**

The ability to set a printer to landscape mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

## LANGUAGE_LEVEL

(PS)

Set this keyword to indicate the language level of the PostScript output that is to be generated by the device. Valid values include 1 (the default) and 2 (required for some features, such as filled patterns for polygons).

## LIGHT

(PS)

Set this keyword to specify that the light version of the current PostScript font should be used.

## MEDIUM

(PS)

Set this keyword to specify that the medium version of the current PostScript font should be used.

## NARROW

(PS)

Set this keyword to specify that the narrow version of the current PostScript font should be used.

## NCAR

(CGM)

Set this keyword to set the encoding type for the CGM output file to NCAR binary.

### The NCAR Binary Encoding

The NCAR binary encoding is used exclusively by the NCAR graphics package. Version 3.01 of NCAR View (`ctrans`, `ictrans`, and `cgm2ncgm`) does not correctly handle the following graphic elements:

- Cell arrays (raster images) with an odd number of pixels in the X dimension. Solution: specify an even number of pixels for the X dimension or make the image one column wider and fill with zeros.
- Raster images drawn in top down order. Solution: invert the image prior to using TV or TVSCL and do not use the /ORDER keyword. For example:

```
TV, image
; Draw image top to bottom:
TV, ROTATE(image, 7)
```

## OBLIQUE

(PS)

Set this keyword to specify that the oblique version of the current PostScript font should be used.

## OPTIMIZE

(PCL)

It is desirable, though not always possible, to compress the size of the PCL output file. Such optimization reduces the size of the output file, and improves I/O speed to the printer. There are three levels of optimization:

| Value | Description |
|---|---|
| 0 | No optimization is performed. This is the default because it will work with any PCL device. However, users of devices which can support optimization should use one of the other optimization levels. |

*Table A-6: PCL Optimization Values*

| Value | Description |
|---|---|
| 1 | Optimization is performed using PCL optimization primitives. This gives the best output compression and printing speed. Unfortunately, not all PCL devices support it. On those that can't, the result will be garbage printed on the page. Consult the programmers manual for your printer to determine if it supports the required escape sequences. The required sequences are: <ESC>*b0M (select full graphics mode), <ESC>*b1M (select compacted graphics mode 1), and <ESC>*b2M (select compacted graphics mode 2). The HP LaserJet II does not support this optimization level. The DeskJet PLUS does. |
| 2 | IDL attempts to optimize the output by explicitly moving the left margin and then outputting non-blank sections of the page. This is primarily intended for use with the LaserJet II, which does not support optimization level 1. Note: This optimization can be very slow on some devices (such as the DeskJet PLUS). On such devices, it is best to avoid this optimization level. |

*Table A-6: PCL Optimization Values (Continued)*

## ORDERED

(PCL, X)

Set this keyword to select the ordered dither method. This introduces a pseudo-random error into the display by using a 4 by 4 "dither" matrix, yielding 16 apparent intensities. This is the default method.

## OUTPUT

(HP, PS)

Specifies a scalar string that is sent directly to the graphics output file without any processing, allowing the user to send arbitrary commands to the file. Since IDL does not examine the string, it is the user's responsibility to ensure that the string is correct for the target device.

## PALATINO

(PS)

Set this keyword to select the Palatino PostScript font.

## PIXELS

(PCL)

Normally, the XOFFSET, XSIZE, YOFFSET, and YSIZE keywords are specified in centimeters. However, if the PIXELS keyword is set, they are taken to be in pixels instead. Note that the selected resolution will determine how large a region is actually written on the page.

## PLOT_TO

(REGIS, TEK)

Directs the Tektronix graphic output that would normally go to the user's terminal to the specified I/O unit. The logical unit specified should be open with write access to a device or file. Graphic output may be saved in files for later playback, redirected to other terminals, or to devices that can accept Textronix graphic commands.

Do not use the interactive graphics cursor when graphic output is not directed to your terminal.

To direct the graphic data to both the terminal and the file, set the unit to the negative of the actual unit number. Alternatively, you can use the TTY keyword, described below.

If the specified unit number is zero then Tektronix output to the file is stopped.

## PLOTTER_ON_OFF

(HP)

There are some configurations in which a HP-GL plotter is connected between the computer and a terminal. In this mode (known as eavesdrop mode), the plotter ignores everything it is sent and passes it through to the terminal—the plotter is logically off. This state continues until an escape sequence is sent that turns the plotter logically on. At this point the plotter interprets and executes all input as HP-GL commands. Another escape sequence is sent at the end of the HP-GL commands to return the plotter to the logically off state.

Most configurations do not use eavesdrop mode, and the plotter is always logically on. However, if you are using this style of connection, you must use PLOTTER_ON_OFF to instruct IDL to generate the necessary on/off commands. If present and non-zero, PLOTTER_ON_OFF causes each output page to be bracketed by device control commands that turn the plotter logically on and off. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

## POLYFILL

(HP)

Some plotters (e.g., HP7550A) can perform polygon filling in hardware, while others (e.g., HP7475) cannot. IDL therefore assumes that the plotter cannot, and generates all polygon operations in software using line drawing. Specifying a non-zero value for the POLYFILL keyword causes IDL to use the hardware polygon filling. Setting it to zero reverts to software filling.

Different implementations of HP-GL plotters may have different limits for the number of vertices that can be specified for a polygon region before the plotter runs out of internal memory. Since this limit can vary, the HP-GL driver cannot check for calls to POLYFILL that specify too many points. Therefore, it is possible for the user to produce HP-GL output that causes an error when sent to the plotter. To avoid this situation, minimize the number of points used. On the HP7550A, the limit is about 127 points. If you do generate output that exceeds the limit imposed by your plotter, you will have to break that polygon filling operation into multiple smaller operations.

## PORTRAIT

(HP, PCL, PRINTER, PS)

Set the PORTRAIT keyword to generate plots using portrait orientation. Portrait orientation is the default. Note that explicitly setting PORTRAIT=0 is the same as setting the LANDSCAPE keyword.

If the current device is PRINTER, and a page is open in the printer, it is closed and a new page set to portrait layout is started.

**Note**

The ability to set a printer to portrait mode is printer-driver dependent. Your printer may not support this functionality; use the system native print setup dialog to set the orientation of the print job.

## PRE_DEPTH

(PS)

Set this keyword to a value indicating the bit depth to be used for the preview in the PostScript file. Valid values are 1 (for black and white preview) and 8 (for 8-bit grayscale preview). This keyword applies only if the PREVIEW keyword is nonzero. The default depth is 8.

## PRE_XSIZE

(PS)

Set this keyword to the width to be used for the preview in the PostScript file. PRE_XSIZE is specified in centimeters, unless the INCHES keyword is set. This keyword applies only if the PREVIEW keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, "A Note About Preview Dimensions".

## PRE_YSIZE

(PS)

Set this keyword to the height to be used for the preview in the PostScript file. PRE_YSIZE is specified in centimeters, unless the INCHES keyword is set. This keyword applies only if the PREVIEW keyword value is nonzero. The default is 1.77778 inches (128 pixels at 72dpi).

Also see the note below, "A Note About Preview Dimensions".

## PREVIEW

(PS)

Set this keyword to 1 to add a platform-independent preview to the PostScript output file in encapsulated PostScript interchange format (EPSI). EPSI is an ASCII format. Set this keyword to 2 to write the EPS file in EPSF format, including an on-screen preview that is supported by many Windows applications, e.g. MSWord. The default (0) is to not include a preview.

**Note**

EPSF is not an ASCII format and cannot be sent directly to a Postscript printer, unlike the EPSI format. It must be imported into an application for printing.

### A Note About Preview Dimensions

Different applications may utilize the information within a PostScript file in different ways when displaying a screen preview. Some applications will ignore the preview contents entirely, and simply use the primary PostScript contents to generate a screen preview. Other applications will use the preview data and its corresponding dimensions for screen display. Still others will use the preview data and stretch it to the dimensions of the primary PostScript contents. It is therefore recommended that the target application (into which the encapsulated PostScript file is to be loaded) be

considered when selecting an appropriate XSIZE, YSIZE, PRE_XSIZE, and PRE_YSIZE.

## PRINT_FILE

(WIN)

Set this keyword to the name of a file (e.g., PostScript or PCL) to be sent to the currently-selected Windows printer. IDL performs no type checking on this file before sending it to the printer. Therefore, if you have a PostScript printer selected and you send a file that contains no valid PostScript information, you'll simply get text output.

To send the file `myfile.ps` to the currently-selected Windows printer, enter:

```
DEVICE, PRINT_FILE='myfile.ps'
```

## PSEUDO_COLOR

(X)

If this keyword is present, the PseudoColor visual is used. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in "X Windows Visuals" on page 3856.

## RESET_STRING

(TEK)

The string used to place the terminal back into the normal interactive mode after drawing graphics. Use this parameter, in conjunction with the SET_STRING keyword, to control the mode switching of your terminal.

For example, the GraphON 200 series terminals require the string `<ESC>2` to activate the alphanumeric window after drawing graphics. The call to set this is:

```
DEVICE, RESET = string(27b) + '2'
```

If the 4100 series mode switch is set, using the keyword TEK4100, the default mode resetting string is `<ESC>%!1`, which selects the ANSI code mode.

## RESOLUTION

(PCL)

### PCL Only

The resolution at which the PCL printer will work. PCL supports resolutions of 75, 100, 150, and 300 dots per inch. The default is 300 dpi. Lower resolution gives smaller output files, while higher resolution gives superior quality.

## RETAIN

(WIN, X)

Use this keyword to specify the default method used for backing store when creating new windows. This is the method used when the RETAIN keyword is not specified with the WINDOW procedure. Backing store is discussed in more detail under “Backing Store” on page 3824, along with the possible values for this keyword. If RETAIN is not used to specify the default method, method 1 (server-supplied backing store) is used.

### Microsoft Windows Only

The initial value of this parameter can be set by selecting File-Preferences from the menu bar. See “Backing Store” on page 3824.

### A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for TVRD. See “Unexpected Results Using TVRD with X Windows” on page 2053.

## SCALE_FACTOR

(PRINTER, PS)

Specifies a scale factor applied to the entire plot. The default value is 1.0, allowing output to appear at its normal size. SCALE_FACTOR is used to magnify or shrink the resulting output.

The SCALE_FACTOR keyword behaves slightly differently in the context of the PRINTER device than it does in the context of the PS device.

When the current device is PRINTER, the SCALE_FACTOR keyword is designed to emulate a scalable resolution setting on the printer. For example, if you have a 300 x 300 pixel image—stored in the variable *image*—the following IDL commands will print *image* in a 0.5 inch square on a 600 dpi printer:

```
SET_PLOT, 'printer'
TV, image
```

Setting SCALE_FACTOR to 2 will scale the image to a 1 inch square on the same 600 dpi printer:

```
SET_PLOT, 'printer'
DEVICE, SCALE_FACTOR=2
TV, image
```

The output of IDL's Direct Graphics routines (CONTOUR, PLOT, SURFACE, etc.) is automatically scaled to fill the available drawing area. As a result, the following IDL commands will produce two identical copies of the same output on any printer:

```
SET_PLOT, 'printer'
PLOT, data
DEVICE, SCALE_FACTOR=2
PLOT, data
```

## SCHOOLBOOK

(PS)

Set this keyword to select the New Century Schoolbook PostScript font.

## SET_CHARACTER_SIZE

(CGM, HP, METAFILE, PCL, PRINTER, PS, REGIS, TEK, WIN, X, Z)

Set this keyword equal to a two-element vector to specify the font size and line spacing (leading) of vector and TrueType fonts, and the line spacing of device fonts. The way that the value of this vector determines character size is not completely intuitive.

The vector specified to the SET_CHARACTER_SIZE keyword sets the values of the X_CH_SIZE and Y_CH_SIZE fields in the !D System Variable structure. These values describe the size of the rectangle that contains the "average" character in the current font. (It is not important what the "average" character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the "average" character is determined by the *width* of the rectangle. The aspect ratio of the "average" character remains fixed;

the character is scaled so that its width fits in the specified rectangle. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines (baseline to baseline) is determined explicitly by the height of the rectangle.

For device fonts, the character size is fixed. When the device font system is in use, the first element of the vector specified to SET_CHARACTER_SIZE is silently ignored, and only the line-spacing value is used.

**Note**

Changing between font systems (and sometimes changing from one font to another within the same font system) can also change the !D structure, so do not assume that the character size you have set is preserved when you change fonts.

## SET_COLORMAP

(PCL)

Set this keyword to a 14,739 ($= 3 \cdot 17^3$) element byte vector containing the RGB-to-printer color translation table for a color PCL printer. The default table is for an HP Deskjet 500C printer.

The translation table is divided into red, green, and blue planes of 4913 ($=17^3$) elements each. For a given RGB triple, the offset into each plane is calculated as follows:

```
Offset = (Red/16)*289 + (Green/16)*17 + (Blue/16)
```

Thus, if the RGB triple is [16,32,160], the offset into each plane is 333. The printer will use the value at element 332 of the translation table as the red value, the value at element 5245 (=4913+332) as the green value, and the value at element 10158 (=9826+332) as the blue value.

The following example shows how to scale an existing colortable for use by a PCL printer.

```
; Set the plot window to the X device:
SET_PLOT, 'X'
; Create a window:
WINDOW,0,XS=300,YS=300
; Load a color table:
LOADCT,13
; Read color table values into variables:
TVLCT,r,g,b,/GET
; Re-size color table variables:
r2=CONGRID(r,4913)
g2=CONGRID(g,4913)
```

```
b2=CONGRID(b,4913)
; Create 14,739-element color map:
colormap=[r2,g2,b2]
; Change to the PCL device:
SET_PLOT, 'PCL'
; Set file name, resolution, color, and color map:
DEVICE, FILE = 'pcl.pcl', RESOLUTION = 300, $
    /COLOR, SET_COLORMAP = colormap
; Display an image:
TVSCL,DIST(900)
; Close the device:
DEVICE,/CLOSE
```

**Note**

The color table used need not be one of IDL's predefined tables.

## SET_COLORS

(Z)

Sets the number of pixel values, !D.N_COLORS and !D.TABLE_SIZE. This value is used by a number of IDL routines to determine the scaling of pixel data and the default drawing index. Allowable values range from 2 to 256, and the default value is 256. Use this parameter to make the Z-buffer device compatible with devices with fewer than 256 colors indices.

## SET_FONT

(METAFILE, PRINTER, PS, WIN, X, Z)

Set this keyword to a scalar string specifying the name of the font used when a hardware or TrueType font is selected. Note that hardware fonts cannot be rotated, scaled, or projected, and that the "!" commands for formatting may not work. When generating three-dimensional plots, it is best to use the vector-drawn or TrueType characters. Note that for the PS device, only one hardware font (other than the predefined fonts set via the fontname keywords, such as /AVANTEGARDE) may be loaded at a time.

### Note on the FONT Keyword

The SET_FONT keyword was introduced with IDL version 5.1 and replaces the FONT and USER_FONT keywords used in previous versions.

### Using TrueType Fonts

For TrueType fonts, the specified font name must exactly match one of the names in the first column of the `ttfont.map` file in the `resource/fonts/tt` directory or

(on Windows platforms) the name of an installed font. See "About TrueType Fonts" on page 3957 for details on the `ttfont.map` file and for a listing of TrueType fonts distributed with IDL. Note that you must include the TT_FONT keyword to indicate that the font specified is a TrueType font. For example, the following sets the font to the font to the TrueType font Helvetica Bold Italic:

```
DEVICE, SET_FONT='Helvetica-BoldItalic'
```

**Note**

You can append additional TrueType fonts to the `ttfont.map` file if desired; on Windows platforms, additional fonts can also be added via the normal font installation procedures for your system. RSI cannot guarantee that TrueType fonts you add will be satisfactorily tessellated or displayed. See "About TrueType Fonts" on page 3957 for details.

### Using Hardware Fonts

Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

#### UNIX

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. X Windows users can use the `xlsfonts` command to list available X Windows fonts.

On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

#### Microsoft Windows

The SET_FONT keyword should be set to a string with the following form:

```
DEVICE, SET_FONT='font*modifier1*modifier2*...modifiern'
```

where the asterisk (*) acts as a delimiter between the font's name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply "keywords" that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY
- For font quality: DRAFT, PROOF
- For font pitch: FIXED, VARIABLE

- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = 'GARAMOND*ITALIC*24'
PLOT, FINDGEN(10), TITLE = 'IDL Plot'
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size.

## SET_GRAPHICS_FUNCTION

(WIN, X, Z)

Most window systems allow applications to specify the graphics function. This is a logical function which specifies how the source pixel values generated by a graphics operation are combined with the pixel values already present on the screen. The complete list of possible values is given in the following table:

| Logical Function | Code | Definition |
|---|---|---|
| GXclear | 0 | 0 |
| GXand | 1 | source AND destination |
| GXandReverse | 2 | source AND (NOT destination) |
| GXcopy | 3 | source |
| GXandInverted | 4 | (NOT source) AND destination |
| GXnoop | 5 | destination |
| GXxor | 6 | source XOR destination |
| GXor | 7 | source OR destination |

*Table A-7: Graphic Function Codes*

| Logical Function | Code | Definition |
|---|---|---|
| GXnor | 8 | (NOT source) AND (NOT destination) |
| GXequiv | 9 | (NOT source) XOR destination |
| GXinvert | 10 | (NOT destination) |
| GXorReverse | 11 | source OR (NOT destination) |
| GXcopyInverted | 12 | (NOT source) |
| GXorInverted | 13 | (NOT source) OR destination |
| GXnand | 14 | (NOT source) OR (NOT destination) |
| GXset | 15 | 1 |

*Table A-7: Graphic Function Codes (Continued)*

The default graphics function is GXcopy, which causes new pixels to completely overwrite any previous pixels. Not all functions are available on all window systems.

For example, the following code segment inverts the bottom bit in the rectangle defined by its diagonal corners $(x_0, y_0)$ and $(x_1, y_1)$:

```
; Set graphics function to exclusive or (GXor), and save the
; old function:
DEVICE, GET_GRAPHICS_FUNCTION = oldg, SET_GRAPHICS_FUNCTION = 6
; Use POLYFILL to select the area to be inverted. The source
; pixel value is 1:
POLYFILL, [[x0,y0], [x0,y1], [x1,y1], [x1,y0]], $
   /DEVICE, COLOR=1
; Restore the previous graphics function:
DEVICE, SET_GRAPHICS_FUNCTION=oldg
```

## SET_RESOLUTION

(Z)

Set this keyword to a two-element vector that specifies the width and height of the Z-buffers. The default size is 640 by 480. If this size is not the same as the existing buffers, the current buffers are destroyed and the device is reinitialized.

## SET_STRING

(TEK)

The string used to place the terminal into the graphics mode from the normal interactive terminal mode. If the 4100 series mode switch is set, using the keyword TEK4100, the default graphic mode setting string is `<ESC>%!0`, which selects the Tektronix code mode.

## SET_TRANSLATION

(X)

This keyword can be used to allow multiple, simultaneous IDL sessions to use the same colors from a shared colormap. Use this keyword before the X connection is established (i.e., before a window is created), IDL will use the shared color map without allocating any additional colors, and will not load a grayscale ramp as is usually done when the X server starts up. The following example shows two cooperating IDL processes sharing the same colormap:

Execute the following commands in the first IDL session:

```
WINDOW, GET_X_ID = a
DEVICE, TRANSLATION = t
OPENW, 1, 'junk.dat'
WRITEU, 1, a, !D.N_COLORS, t[0:!D.N_COLORS-1]
CLOSE, 1
LOADCT, 3
```

Execute the following commands in the second IDL session:

```
OPENR, 1, 'junk.dat'
a=0L
n=0L
READU,1, a, n
t = BYTARR(n)
READU, 1, t
CLOSE, 1
DEVICE, SET_TRANSLATION = t
WINDOW, COLORS=n, SET_X_ID=a
TV, DIST(256)
```

## SET_WRITE_MASK

(X, Z)

Sets the write mask to the specified value. For an *n*-bit system, the write mask can range from 0 to $2^n$-1.

## STATIC_COLOR

(X)

Use this keyword to select the X Windows StaticColor visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in "X Windows Visuals" on page 3856.

## STATIC_GRAY

(X)

Use this keyword to select the X Windows StaticGray visual. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in "X Windows Visuals" on page 3856.

## SYMBOL

(PS)

Set this keyword to select the Symbol PostScript font.

## TEK4014

(TEK)

Set this keyword to specify that coordinates are to be output with full 12-bit resolution. If this keyword is not present or is zero, 10-bit coordinates are output. Normally, IDL sends 10-bit coordinates. 12-bit coordinates are compatible with most terminals, even those without the full resolution, but require more characters to send.

**Note**

The 4014 and the 4100 modes can be used together. The coordinate system IDL uses for the Tektronix is 0 to 4095 in the X direction and 0 to 3120 in the Y direction, even when not in the 4014 mode. In the 10-bit case the internal coordinates are divided by 4 prior to output.

## TEK4100

(TEK)

Set this keyword to indicate that the terminal is a 4100 or 4200 series terminal. The use of color, ANSI and Tektronix mode switching, hardware line styles, and pixel

output with the TV procedure is supported with these terminals. Also, text is output differently.

## TEXT

(CGM)

Set this keyword to set the encoding type for the CGM output file to text.

## THRESHOLD

(PCL, X)

Set this keyword to select the threshold algorithm—the simplest dithering method. The value of this keyword is the threshold to be used. This algorithm simply compares each pixel against the given threshold, usually 128. If the pixel equals or exceeds the threshold the display pixel is set to white, otherwise it is black.

## TIMES

(PS)

Set this keyword to select the Times-Roman PostScript font.

## TRANSLATION

(WIN, X)

As discussed in “Shared Colormaps” on page 3859, using the shared colormap (normally recommended) causes IDL to translate between IDL color indices (which always start with zero and are contiguous) and the pixel values actually present in the display. The TRANSLATION keyword specifies the name of a variable to receive the translation vector. To read the translation table, use the command:

```
DEVICE, TRANSLATION=TRANSARR
```

where TRANSARR is a named variable into which the translation array is stored. The result is a 256-element byte vector. Element zero of the vector contains the pixel value allocated for the first color in the IDL colormap, and so forth.

### Microsoft Windows Only

This keyword is accepted by the WIN device, for compatibility with the X Windows driver, but simply returns a 256-element vector where each element has the value of its subscript (0 to 255).

## TRUE_COLOR

(METAFILE, PRINTER, X)

Use this keyword to select TrueColor visuals. The value of the keyword represents the number of bits per pixel to be used. This keyword has effect only if no windows have been created. Visual classes are discussed in more detail in "X Windows Visuals" on page 3856. If the current device is PRINTER or METAFILE, the printer is placed in RGB or TrueColor mode if the value of the TRUE_COLOR keyword is greater than zero (the number of bits per pixel specified is ignored.)

## TT_FONT

(METAFILE, PRINTER, WIN, X, Z)

Set this keyword to indicate that the font set via the SET_FONT keyword (either to set the fontname or to retrieve fontnames in conjunction with the GET_FONTNAMES or GET_FONTNUM keywords) should be treated as a TrueType font.

## TTY

(REGIS, TEK)

Set this keyword to specify that output should be sent to the terminal at the same time that it is being sent to a file due to the FILENAME or PLOT_TO keywords. A zero value causes output to go only to the file. If no output file is in use, this keyword has no effect.

## USER_FONT

(PS)

*This keyword is now obsolete and has been replaced by the SET_FONT keyword. Code that uses the USER_FONT keyword will continue to function as before, but we suggest that all new code use SET_FONT.*

## VT240, VT241

(REGIS)

Set this keyword to configure the REGIS device for VT240 series terminals.

## VT340, VT341

(REGIS)

Set this keyword to configure the REGIS device for VT340 series terminals.

## WINDOW_STATE

(WIN, X)

Set this keyword to a named variable that returns an array containing one element for each possible window. Array element *i* contains a 1 if window *i* is open, otherwise it contains a 0.

## XOFFSET

(HP, PCL, PRINTER, PS)

Specifies the X position, on the page, of the lower left corner of output generated by IDL. XOFFSET is specified in centimeters, unless INCHES is specified. See "Positioning Graphics Output" on page 3828.

### PostScript Only

SCALE does not affect the value of XOFFSET.

## XON_XOFF

(HP)

If present and non-zero, XON_XOFF causes each output page to start with device control commands that instruct the plotter to obey xon/xoff (^S/^Q) style flow control. Specifying a value of zero stops the issuing of such commands. You should only use this keyword before any output has been generated.

Such handshaking is the default. To turn it off, use the command

```
DEVICE, XON_XOFF=0
```

Often, it is not necessary to tell the plotter to obey flow control because the printing facilities on the system handle such details for you, but it is usually harmless.

## XSIZE

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the width of output generated by IDL. XSIZE is specified in centimeters, unless INCHES is specified.

### PostScript Only

SCALE modifies the value of XSIZE. Hence, the following statement:

```
DEVICE,/INCHES,XSIZE=7.0,SCALE_FACTOR=0.5
```

results in a real width of 3.5 inches.

Also see "A Note About Preview Dimensions" on page 3808.

## YOFFSET

(HP, PCL, PRINTER, PS)

Specifies the Y position, on the page, of the lower left corner of output generated by IDL. YOFFSET is specified in centimeters, unless INCHES is specified. See "Positioning Graphics Output" on page 3828.

**Note**

The corner of the page from which the Y offset is measured (lower or upper left) differs on various devices. Read the device specific information in the following sections to determine how this is handled for your device.

### PostScript Only

SCALE does not affect the value of YOFFSET.

## YSIZE

(HP, METAFILE, PCL, PRINTER, PS)

Specifies the height of output generated by IDL. YSIZE is specified in centimeters, unless INCHES is specified.

### PostScript Only

SCALE modifies the value of YSIZE. Hence, the following statement:

```
DEVICE,/INCHES,YSIZE=5.0,SCALE_FACTOR=0.5
```

results in a real width of 2.5 inches.

Also see "A Note About Preview Dimensions" on page 3808.

## ZAPFCHANCERY

(PS)

Set this keyword to select the ITC Zapf Chancery PostScript font.

## ZAPFDINGBATS

(PS)

Set this keyword to select the ITC Zapf Dingbats PostScript font.

## Z_BUFFERING

(Z)

This keyword enables and disables the Z-buffering. If this keyword is specified with a zero value, the driver operates as a standard 2-D device, the Z-buffering is disabled, and the Z-buffer (if any) is deallocated. Setting this keyword to one (the default value), enables the Z-buffering.

To disable Z-buffering enter:

```
DEVICE, Z_BUFFERING = 0
```

# Window Systems

The different window systems supported by IDL have many features in common. This section describes those features. See the individual descriptions of each system later in this chapter for additional information about each one.

IDL utilizes the window system by creating and using one or more largely independent windows, each of which can be used for the display of graphics and/or images. One color map table is shared among all these windows. Multiple windows can be active simultaneously. Windows are referenced using their index which is a non-negative integer.

"Dithering" or halftoning techniques are used to display images with multiple shades of gray on monochrome displays—displays that can only display white or black. This topic is discussed in "Image Display On Monochrome Devices" on page 3826.

Graphic and image output is always directed to the current window. When a window system is selected as the current IDL graphics device, the index number of the current window is found in the !D.WINDOW system variable. This variable contains -1 if no window is open or selected. The WSET procedure is used to change the current window. WSHOW hides, displays, and iconifies windows. WDELETE deletes a window.

The WINDOW procedure creates a new window with a given index. If a window already exists with the same index, it is first deleted. The size, position, title, and number of colors, may also be specified. If you access the display before creating the first window, IDL automatically creates a window with an index number of 0 and with the default attributes.

## Backing Store

One of the features that distinguishes various window systems is how they handle the issue of backing store. When part of a window that was previously not visible is exposed, there are two basic approaches that a window system can take. Some keep track of the current contents of all windows and automatically repair any damage to their visible regions (retained windows). This saved information is known as the backing store. Others simply report the damage to the program that created the

window and leave repairing the visible region to the program (non-retained windows).

| Value | Description |
|---|---|
| 0 | No backing store. |
| 1 | Request the server or window system to perform backing store. |
| 2 | Make IDL perform backing store. |

*Table A-8: Allowed Values for the RETAIN Keyword*

There are convincing arguments for and against both approaches. It is generally more convenient for IDL if the window system handles this problem automatically, but this often comes at a performance penalty. The actual cost of retained windows varies between systems and depends partially on the application.

The X Window system does not by default keep track of window contents. Therefore, when a window on the display is obscured by another window, the contents of its obscured portion is lost. Re-exposing the window causes the X server to fill the missing data with the default background color for that window, and request the application to redraw the missing data. Applications can request a backing store for their windows, but servers are not required to provide it. Many X servers do not provide backing store, and even those that do cannot necessarily provide it for all requesting windows. Therefore, requesting backing store from the server might help, but there is no certainty.

The IDL window system drivers allow you to control the issue of backing store using the RETAIN keyword to the DEVICE and WINDOW procedures. Using it with DEVICE allows you to set the default action for all windows, while using it with WINDOW lets you override the default for the new window. The possible values for this keyword are summarized under "Backing Store" on page 3824, and are described below:

- Setting the RETAIN keyword to 0 specifies that no backing store is kept. In this case, exposing a previously obscured window leaves the missing portion of the window blank. Although this behavior can be inconvenient, it usually has the highest performance because there is no need to keep a copy of the window contents.
- Setting the RETAIN keyword to 1 causes IDL to request that a backing store be maintained. If the window system decides to accept the request, it will automatically repair the missing portions when the window is exposed. X

Windows may or may not provide backing store when requested, depending on the capabilities of the server and the resources available to it.

- Setting the RETAIN keyword to 2 specifies that IDL should keep a backing store for the window itself, and repair any window damage when the window system requests it. This option exists for X Windows. In this case, a pixmap (off-screen display memory) the same size as the window is created at the same time the window is created, and all graphics operations sent to the window are also sent to the pixmap. When the server requests IDL to repair freshly exposed windows, this pixmap is used to fill in the missing contents. Pixmaps are a precious resource in the X server, so backing pixmaps should only be requested for windows with contents that must absolutely be preserved.

If the type of backing store to use is not explicitly specified using the RETAIN keyword, IDL assumes option 1 and requests the window system to keep a backing store.

### A Note on Reading Data from Windows

On some systems, when backing store is provided by the window system (RETAIN=1), reading data from a window using TVRD may cause unexpected results. For example, data may be improperly read from the window even when the image displayed on screen is correct. Having IDL provide the backing store (RETAIN=2) ensures that the window contents will be read properly. These types of problems are described in more detail in the documentation for TVRD. See “Unexpected Results Using TVRD with X Windows” on page 2053.

## Image Display On Monochrome Devices

Images are automatically dithered when sent to some monochrome devices. Dithering is a technique which increases the number of apparent brightness levels at the expense of spatial resolution. Images with 256 gray levels are displayed on a display with only two colors, black and white, using halftoning techniques. PostScript handles dithering directly. IDL supports dithering for other devices if their DEVICE procedures accept the FLOYD, ORDERED, or THRESHOLD keywords.

# Printing Graphics Output Files

For printer and plotter devices (e.g., PCL, PostScript, and HP-GL), IDL creates a file containing output commands. This file can be sent to the printer via the normal methods provided by the local operating system. When attempting to output the file before exiting IDL, the user must be sure that the graphics output file is complete. For example, the following IDL commands (executed under UNIX) will not produce the desired result:

```
SET_PLOT,'PS'
PLOT,x,y
SPAWN,'lpr idl.ps'
```

These commands fail because the attempt to print the file is premature—the file is still open within IDL and is not yet complete.

The following lines of code are an IDL procedure called OUTPUT_PLOT which closes the current graphics file and sends it to the printer. This routine assumes that the graphics output file is named `idl.xxx`, where `xxx` represents the name of the graphics driver. For example, PostScript output file is assumed to be `idl.ps`. It also assumes that the graphics output to be printed is from the current graphics device, as selected with SET_PLOT.

```
; Close the current graphics file, and print it. If the
; New_file parameter is present, rename the file to the given
; name so it won't be overwritten:
Pro OUTPUT_PLOT, New_file
; Close current graphics file:
DEVICE,/CLOSE
; Build the default output file name by using the idl name for
; the current device (!D.NAME):
file = 'idl.' + STRLOWCASE(!D.NAME)
; Build shell commands to send file to the printer.
; You will probably have to change this command in accordance
; with local usage:
cmd = 'lpr ' + file
; Concatenate rename command if new file specified:
IF N_ELEMENTS(New_file) GT 0 THEN $
   cmd = cmd + '; mv' + file + ' ' + New_file
; Issue shell commands to print/rename file:
SPAWN, cmd
END
```

The call to DEVICE causes IDL to finish the file and close it, which makes it available for printing.

# Setting Up The Printer

In order for IDL generated output files to work properly with printers and plotters, it is necessary for the device to be configured properly. This usually involves configuring both the device hardware and the operating system printing software. When setting up your system, keep the following points in mind:

- The device and computer must use some form of flow control to prevent the computer from sending data faster than the printing device can handle it. The most common form of flow control is known as XON/XOFF, and involves the sending of Control-S (off) and Control-Q (on) characters from the device to the printer to manage the flow of data.

  Many printers have a large buffer into which they store incoming data they haven't yet processed. This reduces the need to invoke flow control. When testing your configuration to ensure flow control is actually enabled, you must be sure to print a document long enough to fill any such buffer, or flow control may never occur, giving a false impression that the setup is correct. A common source of problems stem from attempting to print long IDL generated output files without proper flow control.

- Some devices (such as PCL) require an eight-bit data path, while others (such as PostScript) do not. For devices that do, it is important to ensure that the printer port and system printing software provide such a connection.

  If you are having problems printing on a PostScript printer, the `ehandler.ps` file in the `resource/fonts/ps` subdirectory of the IDL distribution can help you to debug your problem. Sending this file to your PostScript Printer causes it to print any subsequent errors it encounters on a sheet of paper and eject it. The effect of this file lasts until the printer is reset.

## Setting Up Printers Under UNIX

Printers are configured in the `/etc/printcap` file. This file describes to the system which printers are connected to it, the characteristics of each printer, and how the printer port should be configured. Managing the printcap file is usually discussed in the system management documentation supplied with the system by the manufacturer.

# Positioning Graphics Output

The difference between the XOFFSET and YOFFSET keywords to the DEVICE procedure, and the higher level plot positioning keywords and system variables (discussed in Appendix B, "Graphics Keywords" and Chapter 17, "Direct Graphics

Plotting" in the *Using IDL* manual) can lead to confusion. A common misunderstanding is to attempt to use the DEVICE procedure "offset" and "size" keywords multiple times in an attempt to produce multiple plots on a single output page.

The DEVICE keywords are intended to specify the size and position of the entire output area on the page, not to move the plotting region for multiple plots. The driver does not monitor their values continuously, but only when initializing a new page or ejecting the current one.

The proper way to produce multiple plots is to use the high level positioning abilities. The !P.MULTI, !P.POSITION, and !P.REGION system variables can be used to position individual plots on the page. The plotting routines also accept the POSITION, MARGIN and REGION keywords.

## Image Background Color

Graphical output that is displayed with a black background on a monitor frequently look better if the background is changed to white when printed on white paper. This is easily done with the statement:

```
a(WHERE(a EQ 0B)) = 255B
```

# The CGM Device

### Device Keywords Accepted by the CGM Device:

BINARY, CLOSE_FILE, COLORS, ENCODING, FILENAME, NCAR, SET_CHARACTER_SIZE, TEXT

The CGM, Computer Graphics Metafile, standard describes a device independent file format used for the exchange of graphic information. The IDL CGM driver produces CGM files encoded in one of three methods: *Text*, *Binary* or *NCAR Binary*. To direct graphics output to a CGM file, issue the command:

```
SET_PLOT,'CGM'
```

This causes IDL to use the CGM driver for producing graphical output. Once the CGM driver is selected, the DEVICE procedure controls its actions, as described below. Typing `HELP, /DEVICE` displays the current state of the CGM driver. The CGM driver defaults to the binary encoding using 256 colors.

## Abilities and Limitations

This section describes details specific to IDL's CGM implementation:

- IDL uses the CGM default integer encoding for graphic primitives. Coordinate values range from 0 to 32767. It is advisable to use the values stored in !D.X_SIZE and !D.Y_SIZE instead of assuming a fixed coordinate range.
- Color information is output with a resolution of 8 bits (color indices and intensity values range from 0 to 255).
- The definition of background color in the CGM standard is somewhat ambiguous. According to the standard, color index 0 and the background color are the same. Because background color is specified in the metafile as a color value (RGB triple), not an index, it is possible to have the background color not correspond with the color value of index 0.
- The CGM BACKGROUND_COLOUR attribute is explicitly set by IDL only during an erase operation: changing the value of the color map at index 0 does not cause IDL to generate a BACKGROUND_COLOUR attribute until the next ERASE occurs. An ERASE command sets the background color to the value in the color map at index 0. The command `ERASE, INDEX` (where INDEX is not 0) generates the message "`Value of background color is out of allowed range.`" For consistent results, modify the color table before any graphics are output.

- The CGM standard uses scalable (variable size) pixels for raster images. By default, the TV and TVSCL procedures output images, regardless of size, using the entire graphics output area. To output an image smaller than the graphics output area, specify the XSIZE and YSIZE keywords with the TV and TVSCL procedures. For example:

```
; Select the CGM driver:
SET_PLOT, 'CGM'
; Create a 64 x 64 element array:
X = DIST(64)
; Display the image (fills entire screen):
TVSCL, X
; Now display 4 images on the screen:
ERASE
XS = !D.X_SIZE / 2 ; Size of each image, X dimension
YS = !D.Y_SIZE / 2 ; Size of each image, Y dimension
TVSCL, X, 0, XSIZE=XS, YSIZE=YS ; Upper left
TVSCL, X, 1, XSIZE=XS, YSIZE=YS ; Upper right
TVSCL, X, 2, XSIZE=XS, YSIZE=YS ; Lower left
TVSCL, X, 3, XSIZE=XS, YSIZE=YS ; Lower right
```

# The HP-GL Device

## Device Keywords Accepted by the HP-GL Device:

CLOSE_FILE, EJECT, FILENAME, INCHES, LANDSCAPE, OUTPUT, PLOTTER_ON_OFF, POLYFILL, PORTRAIT, SET_CHARACTER_SIZE, XOFFSET, XON_XOFF, XSIZE, YOFFSET, YSIZE

HP-GL (Hewlett-Packard Graphics Language) is a plotter control language used to produce graphics on a wide family of pen plotters. To use HP-GL as the current graphics device, issue the IDL command:

```
SET_PLOT,'HP'
```

This causes IDL to use HP-GL for producing graphical output. Once the HP-GL driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings for the HP-GL driver are shown in the following table. Use the statement:

```
HELP, /DEVICE
```

to view the current state of the HP-GL driver.

| Feature | Value |
|---|---|
| File | idl.hp |
| Orientation | Portrait |
| Erase | No action |
| Polygon filling | Software |
| Turn plotter logically on/off | No |
| Specify xon/xoff flow control | Yes |
| Horizontal offset | 3/4 in. |
| Vertical offset | 5 in. |
| Width | 7 in. |
| Height | 5 in. |

*Table A-9: Default HP-GL Driver Settings*

## Abilities And Limitations

IDL is able to produce a wide variety of graphical output using HP-GL. The following is a list of what is and is not supported:

- All types of vector graphics can be generated, including line plots, contours, surfaces, etc.
- HP-GL plotters can draw lines in different colors selected from the pen carousel. It should be noted that color tables are not used with HP-GL. Instead, each color index refers directly to one of the pens in the carousel.
- Some HP-GL plotters can do polygon filling in hardware. Others can rely on the software polygon filling provided by IDL.
- It is possible to generate graphics using the hardware generated text characters, although such characters do not give much improvement over the standard vector fonts. To use hardware characters, set the !P.FONT system variable to zero, or set the FONT keyword to the plotting routines to zero.
- Since HP-GL is designed to drive pen plotters, it does not support the output of raster images. Therefore, TV and TVSCL do not work with HP-GL.
- Since pen plotters are not interactive devices, they cannot support such operations as cursors and windows.

## HP-GL Linestyles

The LINESTYLE graphics keyword allows specifying any of 6 linestyles. HP-GL does not support all of these linestyles, and styles 3 and 4 differ from the definition in Appendix B, “Graphics Keywords”. The following table summarizes the differences:

| Index | Normal Line Style | HP-GL Line Style |
|---|---|---|
| 0 | Solid | same |
| 1 | Dotted | same |
| 2 | Dashed | same |
| 3 | Dash Dot | Relative size of dash and dot are different. |
| 4 | Dash Dot Dot Dot | Dash Dot Dot |
| 5 | Long Dashes | same |

*Table A-10: Linestyles for the HP-GL Device*

# The Metafile Display Device

## Device Keywords Accepted by the Null Device:

CLOSE_FILE, FILENAME, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GLYPH_CACHE, INCHES, INDEX_COLOR, SET_CHARACTER_SIZE, SET_FONT, TRUE_COLOR, TT_FONT, XSIZE, YSIZE

The Windows Metafile Format (WMF) is used by Windows to store vector graphics in order to exchange graphics information between applications. This format is only available on the Windows platforms. To direct graphics to a file in the WMF format, use the SET_PLOT procedure:

```
SET_PLOT, 'METAFILE'
```

This causes IDL to use the Metafile driver for producing graphical output. Once the Metafile driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions. The default settings are given in the following table:

| Feature | Value |
|---|---|
| File | idl.emf |
| Mode | N/A |
| Horizontal offset | N/A |
| Vertical offset | N/A |
| Width | 7 in. |
| Height | 5 in. |
| Resolution | Screen |

*Table A-11: Default Metafile Driver Settings*

For example, the following will create a WMF file for a simple plot:

```
;Create X and Y Axis data
x=findgen(10)
y=findgen(10)

;Save current device name
mydevice=!D.NAME
```

```
;Set the device to Metafile
SET_PLOT, 'METAFILE'

;Name the file to be created
DEVICE, FILE='test.emf'

;Create the plot
PLOT, x, y

;Close the device which creates the Metafile
DEVICE, /CLOSE

;Set the device back to the original
SET_PLOT, mydevice
```

# The Null Display Device

## Device Keywords Accepted by the Null Device:

No keywords are accepted by the DEVICE procedure when the NULL device is selected.

To suppress graphics output entirely, use the null device:

```
SET_PLOT, 'NULL'
```

# The PCL Device

## Device Keywords Accepted by the PCL Device:

CLOSE_FILE, COLOR, FILENAME, FLOYD, INCHES, LANDSCAPE, OPTIMIZE, ORDERED, PIXELS, PORTRAIT, RESOLUTION, SET_CHARACTER_SIZE, SET_COLORMAP, THRESHOLD, XOFFSET, XSIZE, YOFFSET, YSIZE

PCL (Printer Control Language) is used by Hewlett-Packard laser and ink jet printers to produce graphics output. To direct graphics output to a PCL file, issue the command:

```
SET_PLOT,'PCL'
```

This causes IDL to use the PCL driver for producing graphical output. Once the PCL driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings for the PCL driver are listed in the following table:

| Feature | Value |
|---|---|
| File | idl.pcl |
| Mode | Portrait |
| Optimization level | 0 (None) |
| Dither method | Floyd-Steinberg |
| Resolution | 300 dpi |
| Horizontal offset | 1/2 in. |
| Vertical offset | 1 in. |
| Width | 7 in. |
| Height | 5 in. |

*Table A-12: Default PCL Driver Settings*

The PCL device draws into a memory buffer of the specified size (or the default size, if the XSIZE and YSIZE keywords to DEVICE are not specified). Anything drawn outside this buffer will be silently discarded.

**Note**

Unlike monitors where white is the most visible color, PCL writes black on white paper. Setting the output color index to 0, the default when PCL output is selected, writes in black. A color index of 255 writes white which is invisible on white paper.

Color tables are not used with PCL unless the color mode has been enabled using the COLOR keyword to the DEVICE procedure. For images, color dithering produces realistic color image output even though PCL printers only produce eight output colors. In most cases, simply choosing an appropriate color table (using LOADCT or XLOADCT), or creating a color table from an image (via TVLCT) will work fine. If you need finer control over the colors used, see the SET_COLORMAP keyword for additional information. For vector graphics, only eight colors are supported—no line dithering is implemented. Any RGB component that is not zero is treated as 255. The correct RGB definitions for each color are shown in the following table. Use the `HELP, /DEVICE` command to view the current options for PCL output.

| Color | Red Value | Green Value | Blue Value |
|---|---|---|---|
| Red | 255 | 0 | 0 |
| Green | 0 | 255 | 0 |
| Blue | 0 | 0 | 255 |
| Cyan | 0 | 255 | 255 |
| Magenta | 255 | 0 | 255 |
| Yellow | 255 | 255 | 0 |
| Black | 0 | 0 | 0 |
| White | 255 | 255 | 255 |

*Table A-13: PCL RGB Color Definitions*

# The Printer Device

## Device Keywords Accepted by the PRINTER Device:

CLOSE_DOCUMENT, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GET_PAGE_SIZE, INDEX_COLOR, PORTRAIT, SCALE_FACTOR, SET_CHARACTER_SIZE, TRUE_COLOR, XOFFSET, XSIZE, YOFFSET, YSIZE

The PRINTER device allows IDL Direct Graphics to be output to a system printer. To direct graphics output to a printer, issue the command:

```
SET_PLOT, 'printer'
```

This causes IDL to use a printer driver to produce graphical output. By default, the default system printer is used for output. Use the DIALOG_PRINTERSETUP function to define the printing parameters for the printer device. Use the DIALOG_PRINTJOB function to control the print job itself.

Note that the printer device is an IDL Direct Graphics device. Like other Direct Graphics devices, you must change to the new device and then issue the IDL commands that send output to that device. With the printer device, you must use the CLOSE_DOCUMENT keyword to the DEVICE routine to actually initiate the print job and make something come out of your printer.

# The PostScript Device

## Device Keywords Accepted by the PS Device:

AVANTGARDE, BITS_PER_PIXEL, BKMAN, BOLD, BOOK, CLOSE_FILE, COLOR, COURIER, DEMI, ENCAPSULATED, FILENAME, FONT_INDEX, FONT_SIZE, HELVETICA, INCHES, ISOLATIN1, ITALIC, LANDSCAPE, LIGHT, MEDIUM, NARROW, OBLIQUE, OUTPUT, PALATINO, PORTRAIT, PRE_DEPTH, PRE_XSIZE, PRE_YSIZE, PREVIEW, SCALE_FACTOR, SCHOOLBOOK, SET_CHARACTER_SIZE, SET_FONT, SYMBOL, TIMES, TT_FONT, XOFFSET, XSIZE, YOFFSET, YSIZE, ZAPFCHANCERY, ZAPFDINGBATS

PostScript is a programming language designed to convey a description of a page containing text and graphics. Many laser printers and high-resolution, high-quality photo typesetters support PostScript. Color output or direct color separations can be produced with color PostScript. To direct graphics output to a PostScript file, issue the command:

```
SET_PLOT, 'PS'
```

This causes IDL to use the PostScript driver for producing graphical output. Once the PostScript driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below. The default settings are given in the following table:

| Feature | Value |
|---|---|
| File | idl.ps |
| Mode | Portrait, non-encapsulated, no color |
| Horizontal offset | 3/4 in. |
| Vertical offset | 5 in. |
| Width | 7 in. |
| Height | 5 in. |
| Scale factor | 1.0 |
| Font size | 12 points |

*Table A-14: Default PostScript Driver Settings*

| Feature | Value |
|---|---|
| Font | Helvetica |
| # Bits / Image Pixel | 4 |

*Table A-14: Default PostScript Driver Settings (Continued)*

**Note**

Unlike monitors where white is the most visible color, PostScript writes black on white paper. Setting the output color index to 0, the default when PostScript output is selected, writes black. A color index of 255 writes white which is invisible on white paper. Color tables are not used with PostScript unless the color mode has been enabled using the DEVICE procedure. See "Color Images" on page 3842

To obtain adequate resolution, the device coordinate system used for PostScript output is expressed in units of 0.001 centimeter (i.e., 1000 pixels/cm).

Use the `HELP, /DEVICE` call to view the current font, file, and other options set for PostScript output.

## Using PostScript Fonts

Information necessary for rendering a set of 35 standard PostScript fonts are included with IDL. (The standard 35 fonts are the fonts found on the Apple Laserwriter II PostScript printer; the same fonts are found on almost any PostScript printer made in the time since the LaserWriter II appeared.) Use of PostScript fonts is discussed in detail in "About Device Fonts" on page 3962.

## Color PostScript

If you have a color PostScript device you can enable the use of color with the statement:

```
DEVICE, /COLOR
```

Enabling color also enables the color tables. Text and graphic color indices are translated to RGB by dividing the red, green and blue color table values by 255. As with most display devices, color indices range from 0 to 255. Zero is normally black and white is normally represented by an index of 255. For example, to create and load a color table with four elements, black, red, green and blue:

```
TVLCT, [0,255,0,0], [0,0,255,0], [0,0,0,255]
```

Drawing text or graphics with a color index of 0 results in black, 1 in red, 2 in green, and 3 in blue.

## Color Images

As with black and white PostScript, images may be output with 1, 2, 4, or 8 bits, yielding 1, 2, 16, or 256 possible colors. In addition, images are either pseudo-color or TrueColor. A pseudo-color image is a two dimensional image, each pixel of which is used to index the color table, thereby obtaining an RGB value for each possible pixel value. Pseudo-color images are similar to those displayed using the workstation monitor.

**Note**

In the case of pseudo-color images of fewer than 8 bits, the number of columns in the image should be an exact multiple of the number of pixels per byte (i.e., when displaying 4 bit images the number of columns should be even, and 2 bit images should have a column size that is a multiple of 4). If the image column size is not an exact multiple, extra pixels with a value of 255 are output at the end of each row. This causes no problems if the color white is loaded into the last color table entry, otherwise a stripe of the last (index number 255) color is drawn to the right of the image.

## TrueColor Images

A TrueColor image consists of an array with three dimensions, one of which has a size of three, containing the three color components. It may be considered as three two dimensional images, one each for the red, green and blue components. For example a TrueColor *n* by *m* element image can be ordered in three ways: pixel interleaved (3, *n*, *m*), row interleaved (*n*, 3, *m*), or image interleaved (*n*, *m*, 3). By convention the first color is always red, the second green, and the last is blue.

TrueColor images are also routed through the color tables. The red color table array contains the intensity translation table for the red image, and so forth. Assuming that the color tables have been loaded with the vectors `R`, `G`, and `B`, a pixel with a color value of (*r*, *g*, *b*) is displayed with a color of ($R_r$, $G_g$, $B_b$). As with other devices, a color table value of 255 represents maximum intensity, while 0 indicates an absence of the color. To pass the RGB pixel values without change, load the red, green and blue color tables with a ramp with a slope of 1.0:

```
TVLCT, INDGEN(256), INDGEN(256), INDGEN(256)
```

or with the LOADCT procedure:

```
; Load standard black/white table:
```

```
LOADCT, 0
```

Use the TRUE keyword to the TV and TVSCL procedures to indicate that the image is a TrueColor image and to specify the dimension over which color is interleaved. A value of 1 specifies pixel interleaving, 2 is row interleaving, and 3 is image interleaving. The following example writes a 24-bit image, interleaved over the third dimension, to a PostScript file:

```
SET_PLOT, 'PS'
;Set the PostScript device to *8* bits per color, not 24:
DEVICE, FILE='24bit.ps', /COLOR, BITS=8
TV, [[[r]], [[g]], [[b]]], TRUE=3
DEVICE, /CLOSE
; Return plotting to X windows:
SET_PLOT, 'X'
```

**Note**

Currently, the PostScript device does not support TrueColor plots. Only TrueColor images are supported.

### Image Background Color

Images that are displayed with a black background on a monitor frequently look better if the background is changed to white when displayed with PostScript. This is easily done with the statement:

```
a(WHERE(a EQ 0B)) = 255B
```

## PostScript Positioning

### Using the XOFFSET and YOFFSET Keywords

Often, IDL users are confused by the use of the XOFFSET and YOFFSET keywords to the PostScript DEVICE routine. These keywords control the position of IDL plots on the page. XOFFSET specifies the “X” position of the lower left corner of the output generated by IDL. This offset is always taken relative to the lower left-hand corner of the page when viewed in portrait orientation. YOFFSET specifies the “Y” position of the lower left corner of the output generated by IDL. This offset is also taken relative to the lower left-hand corner of the page when viewed in portrait orientation.

The following figure shows how the XOFFSET and YOFFSET keywords are interpreted by the PostScript device in the Portrait (left) and Landscape (right) modes. Note that the landscape plot uses the same origin for determining the effect of the

XOFFSET and YOFFSET keywords, but that the output is rotated 270 degrees clockwise.

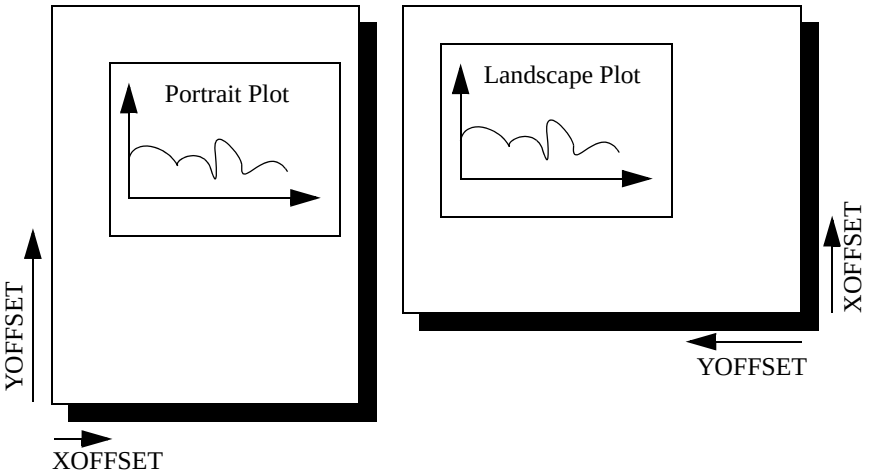

*Figure A-1: Interpretation of the XOFFSET and YOFFSET Keywords*

The page on the left shows an IDL plot printed in "portrait" orientation. Note that the X and Y offsets work just as we expect them to—increasing the XOFFSET moves the plot to the right and increasing the YOFFSET moves the plot up the page. The page on the right shows an IDL plot printed in "landscape" orientation. Here, the X and Y offsets are still taken relative to the same points even though the orientation of the plot has changed. This happens because IDL moves the origin of the plot *before* rotating the PostScript coordinate system 270 degrees clockwise for the landscape plot.

**Note**

The XOFFSET and YOFFSET keywords have no effect when you generate ENCAPSULATED PostScript output.

## Encapsulated PostScript Output

Another form of PostScript output is Encapsulated PostScript. This is the format used to import PostScript files into page layout and desktop publishing programs. An Encapsulated PostScript (EPS) file is similar to a regular PostScript file except that it contains only one page of PostScript output contained in a "bounding box" that is used to tell other programs about the size and aspect ratio of the encapsulated image.

Most of the time, output from IDL to an EPS file is properly scaled into the EPS bounding box because commands such as PLOT take full advantage of the plotting area made available to them. Sometimes, however, the default bounding box is inappropriate for the image being displayed.

As an example, suppose you have an image that is narrow and tall that, when TV'ed to an IDL window, fills only a small portion of the plotting window. Similarly, when output to an EPS file, this image will only fill a small portion of the bounding box. When the resulting EPS file is brought into a desktop publishing program, it becomes very hard to properly scale the image since the aspect ratio of the bounding box bears no relation to the aspect ratio of the image itself.

To solve this problem, use the XSIZE and YSIZE keywords to the DEVICE procedure to make the bounding box just large enough to contain the image. Since IDL uses a resolution of 1000 dots per centimeter with the PostScript device, the correct XSIZE and YSIZE (in centimeters) can be computed as:

- XSIZE = Width of image in pixels/1000.0 pixels per cm
- YSIZE = Height of image in pixels/1000.0 pixels per cm

The following IDL procedure demonstrates this technique. This procedure reads an X Windows Dump file and writes it back out as a properly-sized, 8-bit-color Encapsulated PostScript file:

```
PRO XWDTOEPS, filename
; Read the XWD file. Pixel intensity information is stored
; in the variable 'array'. Values to reconstruct the color
; table are stored in 'r', 'g', and 'b':
array = READ_XWD(filename, r, g, b)
; Reconstruct the color table:
TVLCT, r,g,b
; Display the image in an IDL window:
TV, array
; Find the size of the picture. The width of the picture
; (in pixels) is stored in s[1]. The height of the picture
; is stored in s[2]:
s = SIZE(array)
; Take the 'xwd' (for X Windows Dump) extension off of
; the old filename and replace it with 'eps':
fl = STRLEN(filename)
filename = STRMID(filename, 0, fl-4)
filename = filename + '.eps'
PRINT, 'Making file: ', filename
PRINT, s
; Set the plotting device to PostScript:
SET_PLOT, 'ps'
; Use the DEVICE procedure to make the output encapsulated,
```

```
; 8 bits, color, and only as wide and high as it needs to
; be to contain the XWD image:
DEVICE, /ENCAPSUL, BITS_PER_PIXEL=8, /COLOR, $
   FILENAME=filename, XSIZE=S[1]/1000., $
   YSIZE=S[2]/1000.
; Write the image to the file:
TV, array
; Close the file:
DEVICE, /CLOSE
; Return plotting to X Windows:
SET_PLOT, 'x'
END
```

## Multiple Plots on the Same Page

To put multiple plots on the same PostScript page, use the !P.MULTI system variable (described in more detail in "!P System Variable" on page 3917). !P.MULTI is a 5-element integer array that controls the number of rows and columns of plots to make on a page or in a graphics window.

The first element of !P.MULTI is a counter that reports how many plots remain on the page. The second element of !P.MULTI is the number of columns per page. The third element is the number of rows per page.

For example, the following lines of code create a PostScript file, `multi.ps`, with 6 different plots arranged as 2 columns and 3 rows:

```
; Set plotting to PostScript:
SET_PLOT, 'PS'
; Set the filename:
DEVICE, FILENAME='multi.ps'
; Make IDL's plotting area hold 2 columns and 3 rows of plots:
!P.MULTI = [0, 2, 3]
; Create a simple dataset:
A = FINDGEN(10)
; Make 6 different plots:
PLOT, A
PLOT, SIN(A)
PLOT, COS(A)
PLOT, TAN(A)
PLOT, TANH(A)
PLOT, SINH(A)
; Close the file:
DEVICE, /CLOSE
; Return plotting to Windows:
SET_PLOT, 'win'
; Reset plotting to 1 plot per page:
!P.MULTI = 0
```

The resulting file produces a set of plots as shown in the following figure:

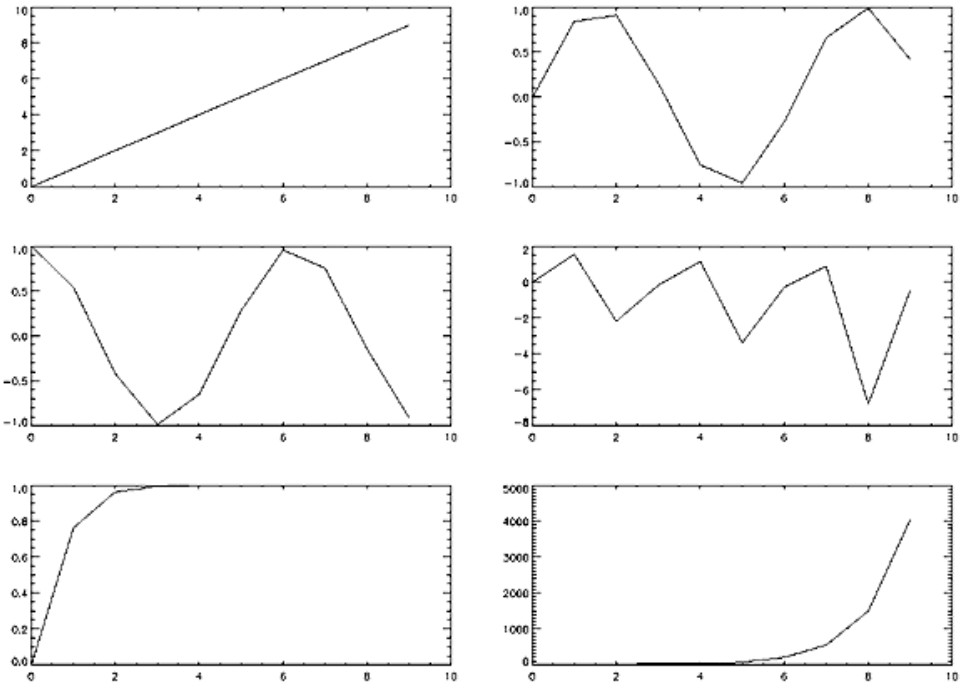

*Figure A-2: Multiple plots on a single page produced by setting the !P.MULTI system variable.*

# Importing IDL Plots into Other Documents

This section shows how to generate IDL PostScript graphics so that they can be inserted into other documents. It also provides several examples of how the PostScript graphics device is used. Simply omit the ENCAPSULATED keyword from the calls to DEVICE if you wish to produce plots that can be printed directly. The following figure is an encapsulated PostScript file suitable for inclusion in other documents. The figure was produced with the following IDL statements. Note the use of the ENCAPSULATED keyword in the call to DEVICE:

```
; Select the PostScript driver:
SET_PLOT, 'PS'
; Note use of ENCAPSULATED keyword:
DEVICE, /ENCAPSULATED, FILENAME = 'pic1.ps'
x = FINDGEN(200)
```

```
    ; Plot the sine wave:
    PLOT, 10000 * SIN(x/5) / EXP(x/100), $
        LINESTYLE = 2, TITLE = 'IDL PostScript Plot', $
        XTITLE = 'Point Number', YTITLE='Y Axis Title', $
        FONT = 0
    ; Add the cosine:
    OPLOT, 10000 * COS(x/5) / EXP(x/100), LINESTYLE = 4
    ; Annotate the plot:
    XYOUTS, 100, -6000, 'Sine', FONT = 0
    OPLOT, [120, 180], [-6000, -6000], LINESTYLE = 2
    XYOUTS, 100, -8000, 'Cosine', FONT = 0
OPLOT, [120, 180], [-8000, -8000], LINESTYLE = 4
```

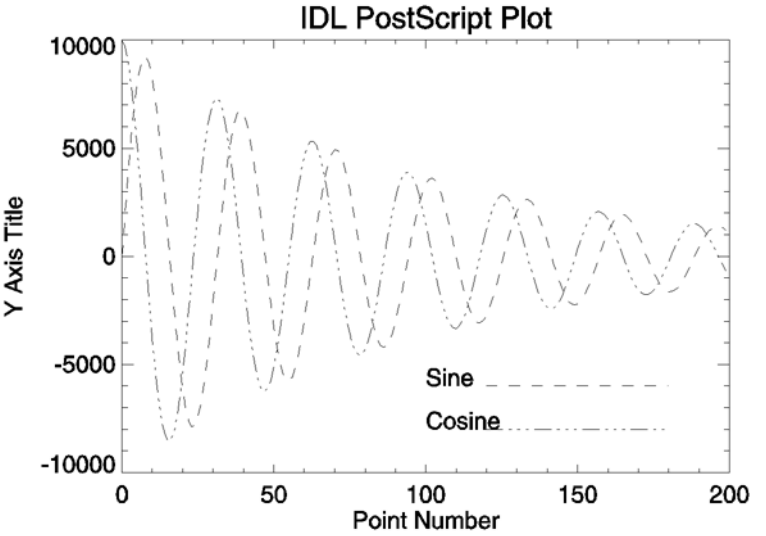

*Figure A-3: Sample PostScript plot using Helvetica font.*

The following figure is a more complicated plot. It demonstrates some of the three-dimensional plotting capabilities of IDL. It was produced with the following IDL statements:

```
    ; Select the PostScript driver:
    SET_PLOT, 'PS'
    ; Note use of ENCAPSULATED keyword:
    DEVICE, /ENCAPSULATED, FILENAME = 'pic2.ps'
    ; Access the data:
    OPENR, 1, FILEPATH('abnorm.dat', SUBDIR=['examples', 'data'])
    aa = ASSOC(1, BYTARR(64, 64))
```

```
   ; Get a smoothed version:
   a = SMOOTH(aa[0], 3)
   ; Generate the surface:
   SURFACE, a, /SAVE, ZAXIS = 1, XSTYLE = 1, YSTYLE = 1
   ; Add the contour:
   CONTOUR, a, /T3D, /NOERASE, ZVALUE = 1, $
      XSTYLE = 1, YSTYLE = 1, C_LINESTYLE = [0,1,2], $
      TITLE = 'IDL PostScript Plot'

CLOSE, 1
```

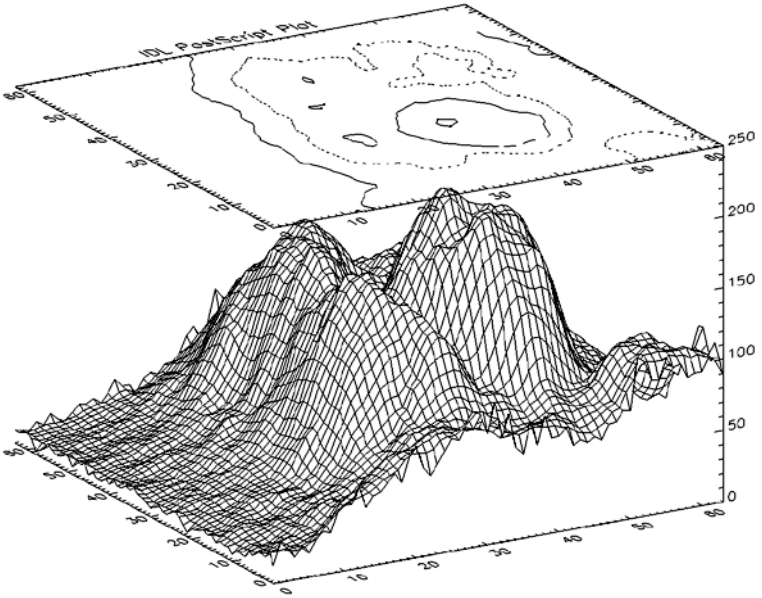

*Figure A-4: Three-Dimensional Plot with Vector-Drawn Characters*

The following figure illustrates polygon filling. It was produced with the following IDL statements:

```
   SET_PLOT, 'PS'
   DEVICE, /ENCAPSULATED, FILENAME = 'pic3.ps'
   x = FINDGEN(200)
   ; Upper sine wave:
   a = 10000 * sin(x / 5) / exp(x / 100)
   PLOT, a, /NODATA, TITLE = 'IDL PostScript Plot', $
      XTITLE='Point Number', YTITLE='Y Axis Title', $
      FONT = 0
```

```
    ; Vector of X vertices for polygon filling. Note that the
    ; ROTATE(V,2) function call returns the vector V in reverse order:
    C = [X, ROTATE(X, 2)]
    ; Vector of Y vertices for polygon filling:
    D = [A, ROTATE(A-2000, 2)]
    ; Fill the region using an intensity of about 75% white:
POLYFILL, C, D, COLOR=192
```

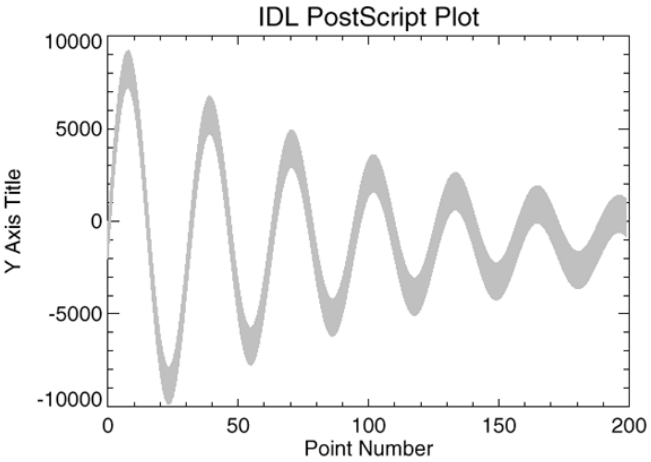

*Figure A-5: Polygon Filling Example*

The following figure illustrates IDL PostScript images. In this case, the same image is reproduced four times. In each case, a different number of bits are used per image pixel. It was produced with the following IDL statements:

```
SET_PLOT, 'PS'
DEVICE, /ENCAPSULATED, FILENAME = 'pic4.ps'
; Open image file:
OPENR, 1, FILEPATH('people.dat', SUBDIR = ['examples','data'])
; Variable to hold image:
a = BYTARR(192, 192, /NOZERO)
; Input the image:
READU, 1, a
; Done with the file:
CLOSE, 1
; Add a color table ramp to the bottom of the image:
A[0,0] = BYTSCL(INDGEN(192))#REPLICATE(1,16)
; Output the image four times:
FOR i = 0,3 DO BEGIN
   ; Use 1, 2, 4, and 8 bits per pixel:
```

```
      DEVICE, BITS_PER_PIXEL=2^i
      ; Output using TV with position numbers 0, 1, 2, and 3:
      TV, a, i, XSIZE=2.5, YSIZE=2.5, /INCHES

ENDFOR
```

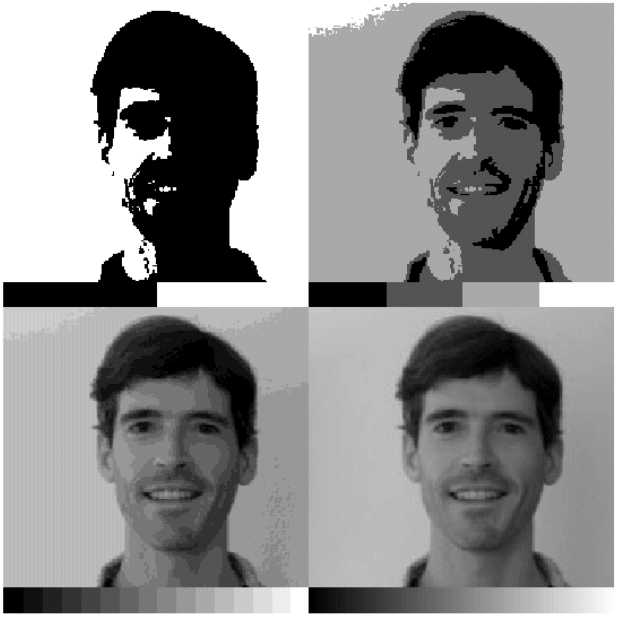

*Figure A-6: 1, 2, 4, and 8-bit PostScript Images*

# The Regis Terminal Device

### Device Keywords Accepted by the REGIS Device:

AVERAGE_LINES, CLOSE_FILE, FILENAME, PLOTTER_ON_OFF, SET_CHARACTER_SIZE, TTY, VT240, VT241, VT340, VT341

IDL provides Regis graphics output for the DEC VT240, VT330, and VT340 series of terminals. To output graphics to such terminals, issue the IDL command:

```
SET_PLOT, 'REGIS'
```

This causes IDL to use the Regis driver for producing graphical output.

## Defaults for Regis Devices

The default setting for Regis output is: VT340, 16 colors, 4 bits per pixel.

## Regis Limitations

- Four colors are available with VT240 and VT241 terminals, sixteen colors are available with the VT330 and VT340.
- Thick lines are emulated by filling polygons. There may be a difference in linestyle appearance between thick and normal lines.
- Image output is slow and is of poor quality, especially on the VT240 series. The VT240 is only able to write pixels on even numbered screen lines. IDL offers two methods of writing images to the 240:
  - Even and odd pairs of rows are averaged and written to the screen. An *n*, *m* image will occupy *n* columns and *m* screen rows. If this method is selected, graphics and image coordinates coincide. This method is the default (`AVERAGE_LINES = 1`). Routines that rely on a uniform graphics and image coordinate system, such as SHADE_SURF, work only in this mode.
  - Each line of the image is written to the screen, displaying every image pixel. An *n*, *m* image occupies 2*m* lines on the screen. (`AVERAGE_LINES = 0`). Graphics and image coordinates coincide only at the lower left corner of the image.
- Pixel values cannot be read back from the terminal, rendering the TVRD function inoperable.

# The Tektronix Device

### Device Keywords Accepted by the REGIS Device:

CLOSE_FILE, COLORS, FILENAME, GIN_CHARS, PLOT_TO, RESET_STRING, SET_CHARACTER_SIZE, SET_STRING, TEK4014, TEK4100, TTY

The Tektronix 4000 (4010, 4014, etc.), 4100 and 4200 series of graphics terminals (and the multitude of terminals and microcomputers that emulate them) are among the most common graphics devices available. To use IDL graphics with such terminals, issue the command:

```
SET_PLOT,'TEK'
```

This causes IDL to use the Tektronix driver for producing graphical output. Once the Tektronix driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, and to configure IDL for the specific features of your terminal. If you never call the DEVICE procedure, IDL assumes a plain vanilla Tektronix 4000 series compatible terminal. The 4200 series is upwardly compatible with the 4100 series; all references to the 4100 series also include the 4200 series. To set up IDL for use with a 4100 series compatible terminal with *n* colors, enter the following commands:

```
SET_PLOT, 'TEK'
DEVICE, /TEK4100, COLORS = n
```

The number of colors should be set to 2B where B is the number of bit planes in your terminal. If you use a Tektronix compatible terminal that requires calling the DEVICE procedure for configuration, you should probably create and use a start-up procedure the calls the DEVICE procedure, as described in Chapter 2. Because of the tremendous variation among the requirements and abilities of these terminals, it is crucial that you configure IDL properly for your terminal. In particular, the mode switching character sequences, set by the keyword parameters SET_STRING and RESET_STRING must be set correctly.

## The DEVICE Procedure For Tektronix Terminals

The default setting for Tektronix output is: 10-bit coordinates, 4000 series terminals, and no use of color. The DEVICE keywords can be used to modify these defaults.

## Tektronix Limitations

- The line drawing procedures work with all models. Line style and color capabilities vary greatly among terminal models and/or emulation programs.

- Color and the display of images (albeit very slowly and frequently of a poor quality because of the small number of colors) is usable only with 4100 series terminals. Hardware polygon fill and thick lines do not work with the 4000 series.
- The image coordinate system does not match the graphics coordinate system. The graphics coordinates range from 0 to 3071 in Y, and from 0 to 4095 in X. Image coordinates vary according to terminal model. A typical range is from 0 to 479 in Y, and 0 to 639 in X. Because of this, the SHADE_SURF procedure does not work with Tektronix terminals.

**Warning**

Not all 4100 series terminals are capable of displaying images—the Tektronix pixel operations option is required. Many terminal emulators do not emulate this option. The Tektronix commands used to output images are: RU, begin pixel operations, RS, set pixel viewport, and RP, raster write. If your terminal or emulator does not accept these commands, you will not be able to display images.

- The Tektronix graphics protocol does not allow the specification of line thickness. Lines with a thickness more than 1.0 are drawn using polygon filling in the case of 4100 series terminals. With 4000 series terminals, thick lines are emulated by drawing multiple thin lines. This scheme will produce artifacts on some Tektronix emulating devices because of differing resolutions, normal line thicknesses and inexact coordinate conversions.

## Tektronix Device Limitations

Usage of Tektronix and Tektronix-compatible terminals with IDL has the following limitations:

- Image coordinates do not match the coordinates used by the rest of the graphic procedures. This is because no two models of Tektronix terminals are compatible. The graphics procedures utilize the default coordinate system of 1024 by 780, or 4096 by 3120 in the 12-bit mode. The size of the pixel memory and coordinate system vary widely between models. The *Position* parameter of the TV and TVSCL procedures does not work.
- The cursor can not be positioned from the computer meaning that the TVCRS procedure cannot be used with the Tektronix driver.
- Pixel values may not be read back from the terminal, rendering the TVRD function inoperable.

# The Microsoft Windows Device

## Device Keywords Accepted by the WIN Device:

BYPASS_TRANSLATION, COPY, CURSOR_CROSSHAIR, CURSOR_ORIGINAL, CURSOR_STANDARD, DECOMPOSED, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GET_GRAPHICS_FUNCTION, GET_SCREEN_SIZE, GET_WINDOW_POSITION, PRINT_FILE, RETAIN, SET_CHARACTER_SIZE, SET_FONT, SET_GRAPHICS_FUNCTION, TRANSLATION, WINDOW_STATE

The Microsoft Windows version of IDL uses the “WIN” device by default. This device is similar to the X Windows device described below. The “WIN” device is only available in IDL for Windows.

To set plotting to the Microsoft Windows device, use the command:

```
SET_PLOT, 'WIN'
```

# The X Windows Device

### Device Keywords Accepted by the X Device:

BYPASS_TRANSLATION, COPY, CURSOR_CROSSHAIR, CURSOR_IMAGE, CURSOR_MASK, CURSOR_ORIGINAL, CURSOR_STANDARD, CURSOR_XY, DECOMPOSED, DIRECT_COLOR, FLOYD, GET_CURRENT_FONT, GET_FONTNAMES, GET_FONTNUM, GET_GRAPHICS_FUNCTION, GET_SCREEN_SIZE, GET_VISUAL_NAME, GET_WINDOW_POSITION, GET_WRITE_MASK, ORDERED, PSEUDO_COLOR, RETAIN, SET_CHARACTER_SIZE, SET_FONT, SET_GRAPHICS_FUNCTION, SET_TRANSLATION, SET_WRITE_MASK, STATIC_COLOR, STATIC_GRAY, THRESHOLD, TRUE_COLOR, TTY, WINDOW_STATE

X Windows is a network-based windowing system developed by MIT's project Athena. IDL uses the X System (often referred to simply as "X"), to provide an environment in which the user can create one or more independent windows, each of which can be used for the display of graphics and/or images.

In the X system, there are two basic cooperating processes: *clients* and *servers*. A server consists of a display, keyboard, and pointer (such as a mouse) as well as the software that controls them. Client processes (such as IDL) display graphics and text on the screen of a server by sending X protocol requests across the network to the server. Although in the most common case, the server and client reside on the same machine, this network based design allows much more elaborate configurations.

To use X Windows as the current graphics device, issue the IDL command:

```
SET_PLOT, 'X'
```

This causes IDL to use the X Window System for producing graphical output. Once the X driver is enabled via SET_PLOT, the DEVICE procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the X Windows driver.

## X Windows Visuals

Visuals specify how the hardware deals with color. The X Window server (your display) may provide colors or only gray scale (black and white), or both. The color

tables may be changeable from within IDL (read-write), or may be fixed (read-only). The value of each pixel value may be mapped to any color (Un-decomposed Colormap), or certain bits of each pixel are dedicated to the red, green, and blue primary colors (Decomposed Colormap).

There are six X Windows visual classes—read-write and read-only visuals for three types of displays: Gray Scale, Pseudo Color, and Decomposed Color. The names of the visuals are shown in the following table:

| Visual Name | Writable | Description |
|---|---|---|
| StaticGray | no | Gray scale |
| GrayScale | yes | Gray scale |
| StaticColor | no | Undecomposed color |
| PseudoColor | yes | Undecomposed color |
| TrueColor | no | Decomposed color |
| DirectColor | yes | Decomposed color |

*Table A-15: X Windows Visual Classes*

IDL supports all six types of visuals, although not at all possible depths. UNIX X Window System users can use the command `xdpyinfo` to determine which visuals are supported by their systems.

Each X Window server has a default visual class. Many servers may provide multiple visual classes. For example, a server with display hardware that supports an 8-bit-deep, un-decomposed, writable color map (PseudoColor), may also easily provide StaticColor, StaticGray, and GrayScale visuals.

You can select the visual used by IDL using the DEVICE procedure before a window is created, or by including the resource `idl.gr_visual` in your X defaults file, as explained in "Setting the X Window Defaults" on page 3864.

## How IDL Selects a Visual Class

When opening the display, IDL asks the display for the following visuals, in order, until a supported visual class is found:

1. DirectColor, 24-bit
2. TrueColor, 24-bit
3. TrueColor, 16-bin (on Linux platforms only)

4. PseudoColor, 8-bit, then 4-bit
5. StaticColor, 8-bit, then 4-bit
6. GrayScale, any depth
7. StaticGray, any depth

You can override this behavior by using the DEVICE routine to specify the desired visual class and depth before you create a window. For example, if you are using a display that supports both the DirectColor, 24-bit-deep visual, and an 8-bit-deep PseudoColor visual, IDL will select the 24-bit-deep DirectColor visual. To instead use PseudoColor, issue the following command before creating a window:

```
DEVICE, PSEUDO_COLOR = 8
```

The colormap/visual class combination is chosen when IDL first connects with the X Window server. Note that if you connect with the X server by creating a window or using the DEVICE keyword to the HELP procedure, the visual class will be set; it then cannot be changed until IDL is restarted. If you wish to use a visual class other than the default, be sure to set it with a call to the DEVICE procedure *before* creating windows or otherwise connecting with the X Window server.

Windows are created in two ways:

1. Using the WINDOW procedure. WINDOW allows you to explicitly control many aspects of how the window is created.
2. If no windows exist and a graphics operation requiring a window is executed, IDL implicitly creates window 0 with the default characteristics.

Once the visual class is selected, all subsequently-created windows share the same class and colormap. The number of simultaneous colors available is stored in the system variable !D.N_COLORS. The visual class and number of colors, once initialized, cannot be changed without first exiting IDL.

## How IDL Obtains a Colormap

IDL chooses the type of colormap in the following manner:

- By default, the shared colormap is used whenever possible (i.e., whenever IDL is using the default visual for the system). All available colors from the shared colormap are allocated for use by IDL. This is what happens when no window currently exists and a graphics operation causes IDL to implicitly create one.
- If the number of colors to use is explicitly specified using the COLORS keyword with the WINDOW procedure, IDL attempts to allocate the number of colors specified from the shared colormap using the default visual of the

screen. If there aren't enough colors available, a private colormap with that number of colors is used instead.

- Specifying a negative value for the COLORS keyword to the WINDOW procedure causes IDL to attempt to use the shared colormap, allocating all but the specified number of colors. For example:

```
WINDOW, COLORS = -8
```

  allocates all but 8 of the currently available colors. This allows other applications that might need their own colors to run in tandem with IDL.

- If a visual type and depth is specified, via the DEVICE procedure, which does not match the default visual of the screen, a new, private, colormap is created.

# Using Color Under X

Colormaps define the mapping from color index to screen color. Two attributes of colormaps are important to the IDL user: they may be *private* or *shared*; and they may be *static* or *writable*. These different types of colormaps are described below.

## Shared Colormaps

The window manager creates a colormap when it is started. This is known as the default colormap, and can be shared by most applications using the display. When each application requires a colormap entry (i.e., a mapping from a color index to a color), it allocates one from this shared table. Advantages and disadvantages of shared colormaps include:

- Using the shared colormap ensures that all applications share the available colors without conflict. A given application will not change a color that is allocated to a different application. In the case of IDL it means that IDL can change the colors it has allocated without changing the colors in use by the window manager or other applications.
- The window system interface routines must translate between the actual and allocated pixel values, significantly slowing the transfer of images.
- The shared colormap might not have enough colors available to perform the desired operations with IDL.
- The number of available colors in the shared colormap depends on the window manager in use and the demands of other applications. Thus, the number of available colors can vary.

- The allocated colors in a shared colormap do not generally start at zero and they are not necessarily contiguous. This makes it difficult to use the write mask for certain operations.

## Private Colormaps

An application can create its own private color map. Most hardware can only display a single colormap at a time, so these private colormaps are called virtual color maps, and only one at a time is actually in use and visible. When the window manager gives the color focus to a window with a private colormap, the X window system loads its virtual colormap into the hardware colormap.

- Every color index supported by the hardware is available to IDL, improving the quality of images.
- Allocated colors always start at zero and are contiguous. This simplifies using the write mask.
- No translation between internal pixel values and the values required by the server is required, making the transfer of images more efficient.
- When the IDL colormap is loaded, other applications are displayed using the wrong colors. Furthermore, colors from the shared colormap are usually allocated from the lower end of the map first. These are the colors allocated by the window manager for such things as window borders, the color of text, and so forth. Since most IDL colormaps have very dark colors in the lower entries, the end effect with the IDL colormap loaded is that the non-IDL portions of the screen go blank.

## Static Colormaps

As mentioned above, the contents of static colormaps are determined outside of IDL and cannot be changed. When using a static colormap, the TVLCT procedure simulates writable colormaps by finding the closest RGB color entry in the colormap to the requested color. The colormap translation table is then set to map IDL color indices to those of the closest colors in the colormap.

The colors present in the colormap may, and probably will, *not* match the requested colors exactly. For example, with a typical static color map, loading the IDL standard color table number 0, which consists of 256 intensities of gray, results in only 8 or 16 distinct intensities.

With static colormaps, loading a new color table does not affect the appearance of previously written objects. The internal translation tables are modified, which only affects objects that are subsequently written.

### Color Translation

As mentioned above, colors from the shared colormap do not necessarily start from index zero, and are not necessarily contiguous. IDL preserves the illusion of a zero based contiguous colormap by maintaining a translation table between user color indices, which range from 0 to !D.TABLE_SIZE, and the actual pixel values allocated from the X server. Normally, the user need not be concerned with this translation table, but it is available using the statement:

```
DEVICE, TRANSLATION=T
```

This statement stores the current translation table, a 256 element byte vector, in the variable T. Element zero of the vector contains the value pixel allocated for the zeroth color in the IDL colormap, and so forth. In the case of a private colormap, each element of the translation vector contains it's own index value, because private colormaps start at zero and are contiguous.

The translation table may be bypassed, allowing direct access to the display's color indices, by setting the BYPASS_TRANSLATION keyword in the DEVICE procedure.

```
DEVICE, /BYPASS_TRANSLATION
```

Translation can be reestablished by setting the keyword to zero:

```
DEVICE, BYPASS_TRANSLATION=0
```

When a private or static (read-only) color table is initialized, the bypass flag is cleared. It is set when initializing a shared color table.

## Using Pixmaps

X Windows can direct graphics to *windows* or *pixmaps*. Windows are the usual windows that appear on the screen and contain graphics. Pixmaps are invisible graphics memory contained in the server. Drawing to a window produces a viewable result, while drawing to a pixmap simply updates the pixmap memory.

Pixmaps are useful because it is possible to write graphics to a pixmap and then copy the contents of the pixmap to a window where it can be viewed. Furthermore, this copy operation is very fast because it happens entirely within the server. Provided enough pixmap memory is available, this technique works very well for animating a series of images by placing the images into pixmap memory and then sequentially copying them to a visible window.

To create a pixmap, use the PIXMAP keyword with the WINDOW procedure. For example, to create a square pixmap with 128 pixels per side as IDL window 1, use the command:

```
WINDOW, 1, /PIXMAP, XSIZE=128, YSIZE=128
```

Once they are created, pixmaps are treated just like normal windows, although some operations (WSHOW for instance) don't do anything useful when applied to a pixmap.

The following procedure shows how animation can be done using pixmap memory. It uses a series of 15 heart images taken from the file `abnorm.dat`. This file is supplied with all IDL distributions in the `examples/data` subdirectory of the main IDL directory. It creates a pixmap and writes the heart images to it. It then uses the COPY keyword of the DEVICE procedure to copy the images to a visible window. Pressing any key causes the display process to halt:

```
; Animate heart series:
PRO animate_heart
; Open the file containing the images:
OPENR, u, FILEPATH('abnorm.dat', SUBDIR = ['examples','data']), $
   /GET_LUN
; Associate a file variable with the file. Each heart image
; is 64x64 pixels:
frame = ASSOC(u, BYTARR(64,64))
; Window pixwin is a pixmap which is 4 images tall and 4
; images wide. The images will be placed in this pixmap:
WINDOW, pixwin, /PIXMAP, XSIZE = 512, YSIZE = 512, /FREE
; Write each image to the pixmap. SMOOTH is used to improve
; the appearance of each image and REBIN is used to
; enlarge/shrink each image to the final display size:
FOR i=0, 15-1 DO TV, REBIN(SMOOTH(frame[i],3), 128, 128),i
; Close the image file and free the file unit:
FREE_LUN, u
; Window win is a visible window. It will be used to display
; the animated heart cycle:
WINDOW, win, XSIZE = 128, YSIZE=128, TITLE='Heart', /FREE
; Current frame number:
i = 0L
; Display frames until any key is pressed:
WHILE GET_KBRD(0) EQ '' DO BEGIN
; Compute x and y locations of pixmap image's lower left corner:
   x = (i mod 4) * 128 & y = 384 - (i/4) * 128
; Copy the next image from the pixmap to the visible window:
DEVICE, COPY = [x, y, 128, 128, 0, 0, pixwin]
; Keep track of total frame count:
i = (i + 1) MOD 15
ENDWHILE
END
```

Animation sequences with more and/or larger images can be made. See the documentation for the XANIMATE procedure, which is a more generalized embodiment of the above procedure.

**Note**

Some X Windows servers will refuse to create a pixmap that is larger than the physical screen in either dimension.

## How Color is Interpreted for a TrueColor Visual

How a color (such as !P.COLOR) is interpreted by IDL (when a TrueColor visual is being utilized) depends in part upon the decomposed setting for the device.

To retrieve the decomposed setting:

```
DEVICE, GET_DECOMPOSED = currentDecomposed
```

To set the decomposed setting:

```
DEVICE, DECOMPOSED = newDecomposed
```

If the decomposed value is zero, colors (like !P.COLOR) are interpreted as indices into IDL's color table. A color should be in the range from 0 to !D.TABLE_SIZE - 1. The IDL color table contains a red, green, and blue component at a given index; each of these components is in the range of 0 up to 255.

**Note**

IDL’s color table does not map directly to a hardware color table for a TrueColor visual. If IDL’s color table is modified, for example using the LOADCT or TVLCT routines, then the new color table will only take effect for graphics that are drawn after it has been modified.

If the decomposed value is non-zero, colors (like !P.COLOR) are interpreted as a combination of red, green, and blue settings. The least significant 8 bits contain the red component, the next 8 bits contain the green component, and the most significant 8 bits contain the blue component.

In either case, the most significant bits of each of the resulting red, green, and blue components are utilized. The number of bits utilized per component depends upon the red, green, and blue masks for the visual. On UNIX systems, a new field (Bits Per RGB) has been added to the output from HELP, /DEVICE. This Bits Per RGB field indicates the amount of bits utilized for each component.

**Tip**

The UNIX command `xdpyinfo` also provides information about each of the visuals.

## Setting the X Window Defaults

You can set the initial default value of the following parameters by setting resources in the file `.Xdefaults` file in your home directory as follows:

| Resource Name | Description |
|---|---|
| idl.colors | The number of colors used by IDL. |
| idl.gr_depth | The depth, in bits, of the visual used by IDL. |
| idl.retain | The default setting for the *`retain`* parameter: 0=none, 1= by server, 2=by IDL. |
| idl.gr_visual | The type of visual: StaticGray, GrayScale, StaticColor, PseudoColor, TrueColor, or DirectColor. |

*Table A-16: IDL/ X Window Defaults*

For example, to set the default visual to PseudoColor, and to allocate 100 colors, insert the following lines in your defaults file:

```
idl.gr_visual: PseudoColor
idl.colors: 100
```

# The Z-Buffer Device

## Device Keywords Accepted by the Z Device:

CLOSE, GET_GRAPHICS_FUNCTION, GET_WRITE_MASK, SET_CHARACTER_SIZE, SET_COLORS, SET_FONT, SET_GRAPHICS_FUNCTION, SET_RESOLUTION, Z_BUFFERING

The IDL Z-buffer device is a pseudo device that draws 2-D or 3-D graphics in a buffer contained in memory. This driver implements the classic Z buffer algorithm for hidden surface removal. Although primarily used for 3-D graphics, the Z-buffer driver can be used to create 2-D objects in a frame buffer in memory. The resolution of this device can be set by the user.

All of the IDL plotting and graphics routines work with the Z-buffer device driver. In addition, the POLYFILL procedure has a few keyword parameters, allowing Gouraud shading and warping images over 3-D polygons, that are only effective when used with the Z-buffer.

When used for 3-D graphics, two buffers are present: an 8-bit-deep frame buffer that contains the picture; and a 16-bit-deep Z-buffer of the same resolution, containing the z-value of the visible surface of each pixel. The Z-buffer is initialized to the depth at the back of the viewing volume. When objects are drawn, the z-value of each pixel is compared with the value at the same location in the Z-buffer, and if the z-value is greater (closer to the viewer), the new pixel is written in the frame buffer and the Z-buffer is updated with the new z-value.

The Z-buffer device is a “pseudo device” in that drawing commands update buffers in memory rather than sending commands to a physical device or file. The TVRD function reads the contents of either buffer to an IDL array. This array may then be further processed, written to a file, or output to a raster-based graphics output device.

The Z-buffer driver can be used for 2-D graphics by disabling the depth computations.

To use the Z-buffer as the current graphics device, issue the IDL command:

```
SET_PLOT, 'Z'
```

Once the Z-buffer driver is enabled the DEVICE procedure is used to control its actions, as described below.

Use the statement:

```
HELP, /DEVICE
```

to view the current state of the Z-buffer driver and the amount of memory used for the buffers.

## Reading and Writing Buffers

The contents of both buffers are directly accessed by the TV and TVRD routines. The frame buffer that contains the picture is 8 bits deep and is accessed as channel 0. The Z depth buffer contains 16 bit integers and is accessed as channel 1. Always use `CHANNEL=1` and set the keyword WORDS when reading or writing the depth buffer.

The normal procedure is to set the graphics device to “Z”, draw the objects, read the frame buffer, and then select another graphics device and write the image. For example, to create an image with the Z-buffer driver and then display it on an X-Window display:

```
; Select Z-buffer device:
SET_PLOT,'Z'
; Write objects to the frame buffer using normal graphics
; routines, e.g. PLOT, SURFACE, POLYFILL
... ... ...
; Read back the entire frame buffer:
a=TVRD()
; Select X Windows:
SET_PLOT,'X'
; Display the contents of the frame buffer:
TV, a
```

To read the depth values in the Z-buffer, use the command:

```
a = TVRD(CHANNEL=1, /WORDS)
```

To write the depth values, use the command:

```
TV, a, /WORDS, CHANNEL=1
```

The TV, TVSCL, and TVRD routines write or read pixels directly to a rectangular area of the designated buffer without affecting the other buffer.

## Z-Axis Scaling

The values in the depth buffer are short integers, scaled from -32765 to +32765, corresponding to normalized Z-coordinate values of 0.0 to 1.0.

## Polyfill Procedure

The following POLYFILL keywords are active only with the Z-buffer device: IMAGE_COORDINATES, IMAGE_INTERPOLATE, and TRANSPARENT. These

parameters allow images, specified via the PATTERN keyword, to be warped over 2-D and 3-D polygons.

The IMAGE_COORDINATES keyword contains a 2 by *N* array containing the image space coordinates that correspond to each of the *N* vertices of the polygon. The IMAGE_INTERPOLATE keyword indicates that bilinear interpolation is to be used, rather than the default nearest neighbor sampling. Pixels less than the value of TRANSPARENT are not drawn, simulating transparency. For Gouraud shading of polygons, the COLOR keyword can contain an array specifying the color index for each polygon vertex.

## Examples Using the Z-Buffer

This example forms a Bessel function, draws its shaded surface and overlays its contour, using the Z-buffer as shown in the following figure.The final output is directed to PostScript.

```
; Select the Z-buffer:
SET_PLOT, 'Z'
n = 50 ; Size of array for Bessel
; Make the Bessel function:
a = BESELJ(SHIFT(DIST(n), n/2, n/2)/2, 0)
; Draw the surface, label axes in black, background in white:
SHADE_SURF, a, /SAVE, COLOR=1, BACKGROUND=255
nlev = 8 ; Number of contour levels
; Make the Contour at normalized Z=.6:
CONTOUR, a, /OVERPLOT, ZVALUE=.6, /T3D, $
   LEVELS=FINDGEN(nlev)*1.5/nlev-.5, COLOR=1
; Read image:
b=TVRD()
; Select PostScript output:
SET_PLOT, 'PS'
; Output the image:
TV, b
; Close the new PostScript file:
DEVICE, /CLOSE
```

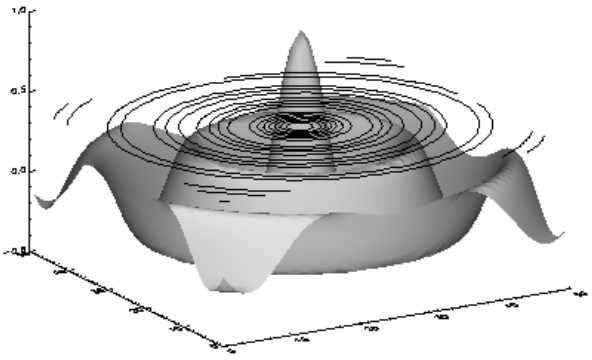

*Figure A-7: Combined Shaded Surface and Contour Plot*

The following example warps an image to a cube as shown in the figure below. The lower two quadrants of the image are warped to the front two faces of the cube. The upper-right quadrant is warped to the top face of the cube. The image is held in the array a, with dimensions nx by ny. The image is then output to PostScript as in the previous example.

```
; Select the Z-buffer:
SET_PLOT, 'Z'
; Make a white background for final output to PostScript:
ERASE, 255
; Establish 3-D scaling as (0,1) cube:
SCALE3, XRANGE=[0,1], YRANGE=[0,1], ZRANGE=[0,1]
; Define vertices of cube. Vertices 0-3 are bottom, 4-7 are top:
verts = [[0,0,0], [1,0,0], [1,1,0], [0,1,0], $
   [0,0,1], [1,0,1], [1,1,1], [0,1,1]]
; Fill lower left face:
POLYFILL, verts[*, [3,0,4,7]], /T3D, PATTERN=a, $
   IMAGE_COORD=[[0,0], [nx/2,0], [nx/2,ny/2], [0,ny/2]]
; Fill lower right face:
POLYFILL, verts[*, [0,1,5,4]], /T3D, PATTERN=a, $
   IMAGE_COORD=[[nx/2,0], [nx-1,0], $
   [nx-1,ny/2], [nx/2,ny/2]]
; Fill top face:
POLYFILL, verts[*, [4,5,6,7]], /T3D, PATTERN=a, $
   IMAGE_COORD = [[nx/2,ny/2], [nx-1,ny/2], $
   [nx-1,ny-1], [nx/2,ny-1]]
; Draw edges of cube in black:
PLOTS, verts[*, [0,4]], /T3D, COLOR=0
```

```
   ; Edges of top face:
PLOTS, verts[*, [4,5,6,7,4]], /T3D, COLOR=0
```

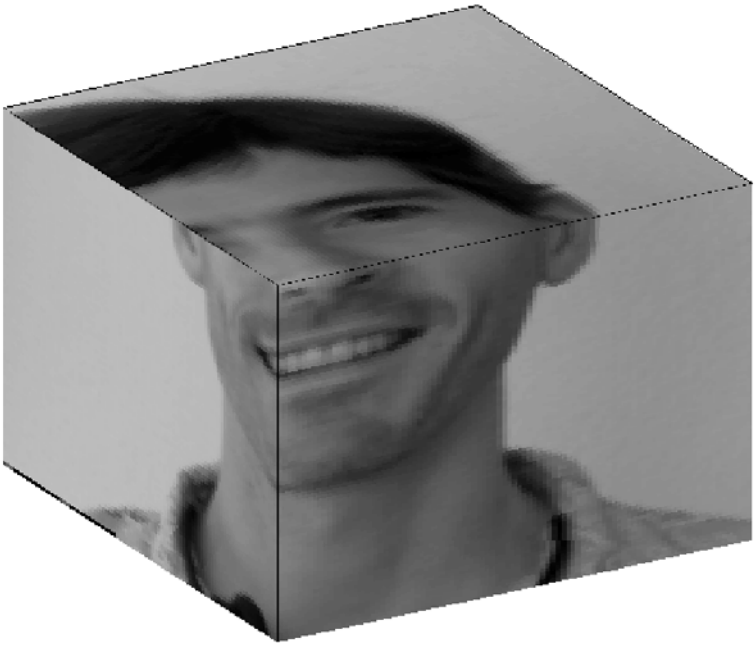

*Figure A-8: Image Warped to a Cube Using the Z-Buffer*

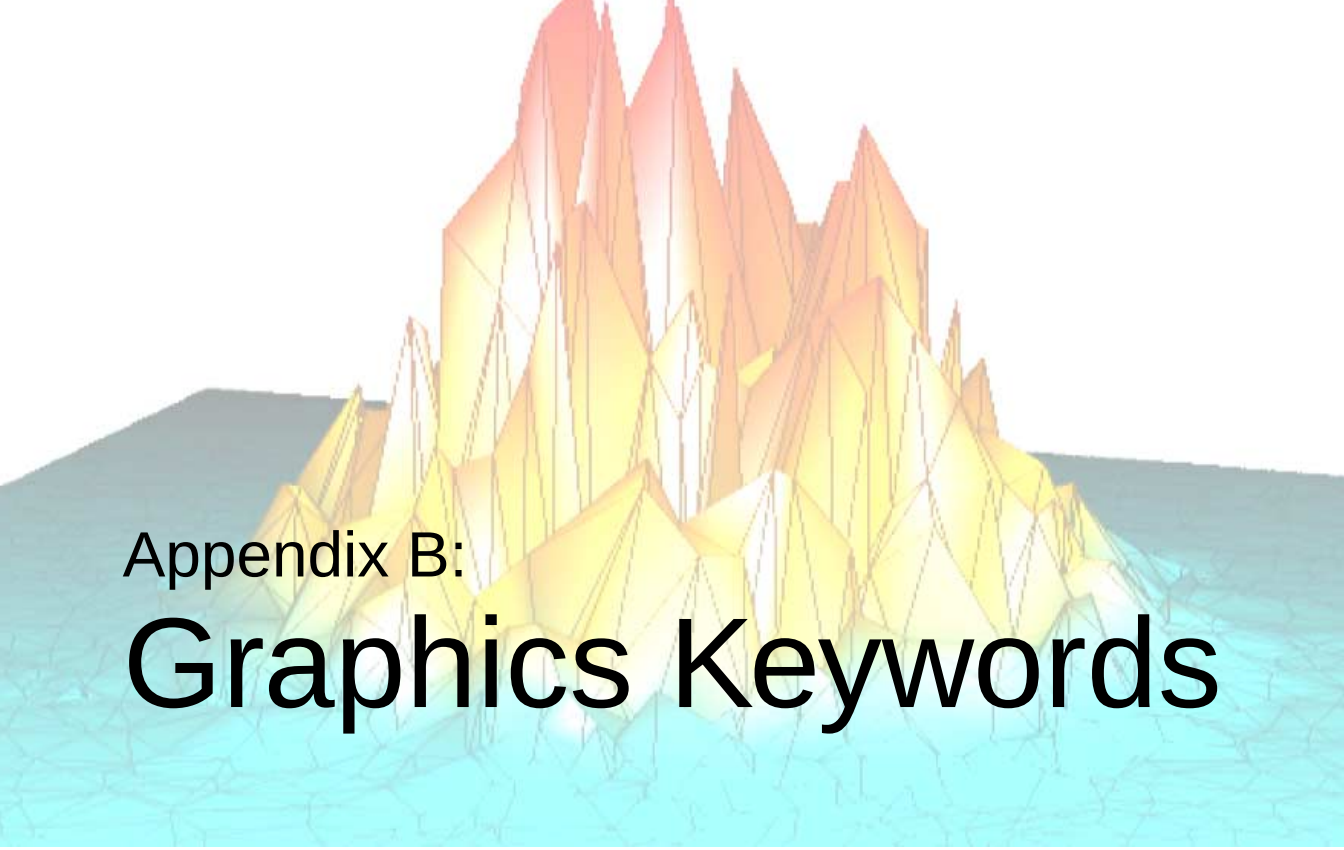

# Appendix B: Graphics Keywords

The IDL Direct Graphics routines, CURSOR, ERASE, PLOTS, POLYFILL, TV (and TVSCL), TVCRS, TVRD, and XYOUTS, and the plotting procedures, AXIS, CONTOUR, PLOT, OPLOT, SHADE_SURF, and SURFACE, accept a number of common keywords. Therefore, instead of describing each keyword along with the description of each routine, this section contains a brief summary of each graphics keyword. Routine-specific keywords are documented in the description of the routine.

The graphics keywords are described below. The name of each keyword is followed by a list of routines that accept that keyword. Keywords that have a direct correspondence to fields in a system variable (usually !P) are also indicated.

The keywords that control the plot axes are prefixed with the character ‘X’, ‘Y’, or ‘Z’ depending on the axis in question. These keywords correspond to fields in the axis system variables: !X, !Y, and !Z, and are described in more detail in “Graphics System Variables” on page 3913 The axis keywords are shown in the form [XYZ]NAME. For example, [XYZ]CHARSIZE refers to the three keywords XCHARSIZE, YCHARSIZE, and ZCHARSIZE, which control the size of the characters annotating the three axes.

The system variable fields that control this are !X.CHARSIZE, !Y.CHARSIZE, and !Z.CHARSIZE.

The following graphics keywords are discussed in this appendix:

# BACKGROUND

Accepted by: CONTOUR, PLOT, SURFACE.

System variable equivalent: !P.BACKGROUND.

The background color index to which all pixels are set when erasing the screen or page. The default is 0 (black). Not all devices support erasing the background to a specified color index.

For example, to produce a black plot with a white background on a color display:

```
PLOT, Y, BACKGROUND = 255, COLOR = 0
```

# CHANNEL

Accepted by: ERASE, TV, TVRD. System variable equivalent: !P.CHANNEL.

This keyword specifies the memory channel for the operation. This parameter is ignored on display systems that have only one memory channel. When using a "decomposed" display system, the red channel is 1, the green channel is 2, and the blue channel is 3. Channel 0 indicates all channels. If omitted, !P.CHANNEL contains the default channel value.

**Note**

CONTOUR, PLOT, SHADE_SURF, and SURFACE also accept the CHANNEL keyword, but simply pass it to ERASE.

## CHARSIZE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE, XYOUTS. System variable equivalent: !P.CHARSIZE.

The overall character size for the annotation when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. A CHARSIZE of 1.0 is normal. The size of the annotation on the axes may be set, relative to CHARSIZE, with *x*CHARSIZE, where *x* is X, Y, or Z. The main title is written with a character size of 1.25 times this parameter.

## CHARTHICK

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE, XYOUTS. System variable equivalent: !P.CHARTHICK.

An integer value specifying the line thickness of the vector drawn font characters.This keyword has no effect when used with the hardware drawn fonts. The default value is 1.

## CLIP

Accepted by: CONTOUR, DRAW_ROI, OPLOT, PLOT, PLOTS, POLYFILL, SURFACE, XYOUTS. System variable equivalent: !P.CLIP.

The coordinates of a rectangle used to clip the graphics output. The rectangle is specified as a vector of the form $[X_0, Y_0, X_1, Y_1]$, giving coordinates of the lower left and upper right corners, respectively. The default clipping rectangle is the plot window, the area enclosed within the axes of the most recent plot. Coordinates are specified in data units unless an overriding coordinate unit specification keyword is present (i.e., NORMAL or DEVICE). If the clipping is provided in data or

normalized units, the actual clipping rectangle is computed by converting those values to device units. The clipping itself always occurs in device space.

**Note**

The default is not to clip the output of PLOTS and XYOUTS. To enable clipping include the keyword parameter NOCLIP = 0. With PLOTS, POLYFILL, and XYOUTS, this keyword controls the clipping of vectors and vector-drawn text.

For example, to draw a vector using normalized coordinates with its contents clipped within a rectangle covering the upper left quadrant of the display:

```
PLOTS, X, Y, CLIP=[0.,.5,.5,1.0], /NORM, NOCLIP=0
```

## COLOR

Accepted by: AXIS, CONTOUR, DRAW_ROI, ERASE, OPLOT, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, XYOUTS. System variable equivalent: !P.COLOR.

The color index of the data, text, line, or solid polygon fill to be drawn. If this keyword is omitted, !P.COLOR specifies the color index.

When used with the PLOTS, POLYFILL, or XYOUTS procedure, this keyword parameter can be set to a vector to specify multiple color indices.

Gouraud shading of polygons is performed with the Z-buffer graphics output device and POLYFILL procedure when COLOR contains an array of color indices, one for each vertex.

## DATA

Accepted by: AXIS, CONTOUR, CURSOR, DRAW_ROI, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, TV, TVCRS, XYOUTS.

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the data coordinate system. The default coordinate system is DATA if no other coordinate-system specifications are present.

## DEVICE

AXIS, CONTOUR, CURSOR, DRAW_ROI, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, TV, TVCRS, XYOUTS.

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the device coordinate system. The default coordinate system is DATA if no other coordinate-system specifications are present.

For example, the following code displays an image contained in the variable A and then draws a contour plot of pixels [100:499, 100:399] over the correct section of the image:

```
;Display the image.
TV,A

;Draw the contour plot, specify the coordinates of the plot, in
;device coordinates, do not erase, set the X and Y axis styles to
;EXACT.
CONTOUR, A[100:499, 100:399], $
    POS = [100,100, 499,399], /DEVICE, $
   /NOERASE, XSTYLE=1, YSTYLE=1
```

Note that in the above example, the keyword specification `/DEVICE` is equivalent to `DEVICE = 1`.

## FONT

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE, XYOUTS. System variable equivalent: !P.FONT.

An integer that specifies the graphics text font system to use. Set FONT equal to -1 to selects the Hershey character fonts, which are drawn using vectors. Set FONT equal to 0 (zero) to select the device font of the output device. Set FONT equal to 1 (one) to select the TrueType font system. See Appendix H, “Fonts” for a complete description of IDL’s font systems.

## LINESTYLE

Accepted by: DRAW_ROI, OPLOT, PLOT, PLOTS, SURFACE. System variable equivalent: !P.LINESTYLE.

This keyword indicates the line style used to draw lines; it indicates the line style of the lines used to connect the data points. This keyword should be set to the appropriate index for the desired linestyle as described in the following table.

| Index | Linestyle |
|---|---|
| 0 | Solid |
| 1 | Dotted |
| 2 | Dashed |
| 3 | Dash Dot |
| 4 | Dash Dot Dot |
| 5 | Long Dashes |

*Table B-1: IDL Linestyles*

## NOCLIP

Accepted by: CONTOUR, DRAW_ROI, OPLOT, PLOT, PLOTS, POLYFILL, SURFACE, XYOUTS. System variable equivalent: !P.NOCLIP.

Set this keyword to suppress clipping of the plot. The clipping rectangle is contained in !P.CLIP. By default, the plot is clipped within the plotting window.

**Note**

The default value is clipping-disabled for PLOTS, POLYFILL, and XYOUTS. For all other routines, the default is to enable clipping.

With PLOTS, POLYFILL, and XYOUTS, this keyword controls the clipping of vectors and vector-drawn text. The default is to disable clipping, so to enable clipping include the parameter NOCLIP = 0. To explicitly disable clipping set this parameter to one.

## NODATA

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE.

If this keyword is set, only the axes, titles, and annotation are drawn. No data points are plotted.

For example, to draw an empty set of axes between some given values:

```
PLOT, [XMIN, XMAX],[YMIN, YMAX], /NODATA
```

## NOERASE

Accepted by: AXIS, CONTOUR, PLOT, SURFACE. System variable equivalent: !P.NOERASE.

Specifies that the screen or page is not to be erased. By default, the screen is erased, or a new page is begun, before a plot is produced.

## NORMAL

Accepted by: AXIS, CONTOUR, CURSOR, DRAW_ROI, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, TV, TVCRS, XYOUTS.

Set this keyword to indicate that the clipping and/or positioning coordinates supplied are specified in the normalized coordinate system, and range from 0.0 to 1.0. The default coordinate system is DATA if no other coordinate-system specifications are present.

## ORIENTATION

Accepted by: DRAW_ROI, POLYFILL, XYOUTS.

Specifies the counterclockwise angle in degrees from horizontal of the text baseline and the lines used to fill polygons.When used with the POLYFILL procedure, this keyword forces the “linestyle” type of fill, rather than solid or patterned fill.

## POSITION

Accepted by: CONTOUR, MAP_SET, PLOT, SHADE_SURF, SURFACE. System variable equivalent: !P.POSITION.

Allows direct specification of the plot window. POSITION is a 4-element vector giving, in order, the coordinates [($X_0$, $Y_0$), ($X_1$, $Y_1$)], of the lower left and upper right corners of the data window. Coordinates are expressed in normalized units ranging from 0.0 to 1.0, unless the DEVICE keyword is present, in which case they are in actual device units. The value of POSITION is never specified in data units, even if the DATA keyword is present.

When setting the position of the window, be sure to allow space for the annotation, which resides outside the window. IDL outputs the message “% Warning: Plot truncated.” if the plot region is larger than the screen or page size. The plot region is the rectangle enclosing the plot window and the annotation.

When plotting in three dimensions, the POSITION keyword is a 6-element vector with the first four elements describing, as above, the XY position, and with the last two elements giving the minimum and maximum Z coordinates. The Z specification is always in normalized coordinate units.

When making more than one plot per page it is more convenient to set !P.MULTI than to manipulate the position of the plot directly with the POSITION keyword.

For example, the following statement produces a contour plot with data plotted in only the upper left quarter of the screen:

```
CONTOUR, Z, POS=[0., 0.5, 0.5, 1.0]
```

Because no space on the left or top edges was allowed for the axes or their annotation, the above described warning message results.

# PSYM

Accepted by: DRAW_ROI, OPLOT, PLOT, PLOTS. System variable equivalent: !P.PSYM.

The symbol used to mark each data point. Normally, PSYM is 0, data points are connected by lines, and no symbols are drawn to mark the points. Set this keyword, or the system variable !P.PSYM, to the symbol index as shown in the table below to mark data points with symbols. The keyword SYMSIZE is used to set the size of the symbols.

| PSYM Value | Plotting Symbol |
|---|---|
| 1 | Plus sign (+) |
| 2 | Asterisk (*) |
| 3 | Period (.) |
| 4 | Diamond |
| 5 | Triangle |
| 6 | Square |
| 7 | X |
| 8 | User-defined. See USERSYM procedure. |

*Table B-2: Values for the PSYM Keyword*

| PSYM Value | Plotting Symbol |
|---|---|
| 9 | Undefined |
| 10 | Histogram mode. Horizontal and vertical lines connect the plotted points, as opposed to the normal method of connecting points with straight lines. |

*Table B-2: Values for the PSYM Keyword*

Negative values of PSYM cause the symbol designated by PSYM to be plotted at each point with solid lines connecting the symbols. For example, a value of -5 plots triangles at each data point and connects the points with lines. Histogram mode is the exception to this rule; since the points are already connected when PSYM=10, specifying the value -10 is meaningless, and will result in an error.

The following IDL code plots an array using points, and then overplots the smoothed array, connecting the points with lines:

```
;Plot using points.
PLOT, A, PSYM=3

;Overplot smoothed data.
OPLOT, SMOOTH(A,7)
```

## SUBTITLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: !P.SUBTITLE.

A text string to be used as a subtitle for the plot. Subtitles appear below the X axis.

## SYMSIZE

Accepted by: DRAW_ROI, OPLOT, PLOT, PLOTS.

Specifies the size of the symbols drawn when PSYM is set. The default size of 1.0 produces symbols approximately the same size as a character.

## T3D

Accepted by: AXIS, CONTOUR, DRAW_ROI, MAP_SET, OPLOT, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE, TV, TVCRS, XYOUTS. System variable equivalent: !P.T3D.

Set this keyword to indicate that the generalized transformation matrix in !P.T is to be used. If not present, the user-supplied coordinates are simply scaled to screen coordinates. See the examples in the description of the SAVE keyword.

**Note**

Since T3D uses the transformation matrix in !P.T, it is important that !P.T contain a valid transformation matrix. This can be achieved in several ways:

- Use the SAVE keyword to save the transformation matrix from an earlier graphics operation.
- Establish a transformation matrix using the T3D, SURFR, or, SCALE3 procedures.
- Set the value of !P.T directly.

## THICK

Accepted by: AXIS, DRAW_ROI, OPLOT, PLOT, PLOTS, POLYFILL, SHADE_SURF, SURFACE. System variable equivalent: !P.THICK.

Indicates the line thickness. THICK overrides the setting of !P.THICK.

## TICKLEN

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: !P.TICKLEN.

Controls the length of the axis tick marks, expressed as a fraction of the window size. The default value is 0.02. TICKLEN of 1.0 produces a grid, while a negative TICKLEN makes tick marks that extend outside the window, rather than inwards.

For example, to produce outward-going tick marks of the normal length:

```
PLOT, X, Y, TICKLEN = -0.02
```

To provide a new default tick length, set !P.TICKLEN.

## TITLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: !P.TITLE.

Produces a main title centered above the plot window. The text size of this main title is larger than the other text by a factor of 1.25. For example:

```
PLOT, X, Y, TITLE = 'Final Results'
```

## [XYZ]CHARSIZE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalents: ![XYZ].CHARSIZE.

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This keyword does not apply when hardware (i.e. PostScript) fonts are selected. This field is a scale factor applied to the global scale factor set by !P.CHARSIZE or the keyword CHARSIZE.

## [XYZ]GRIDSTYLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE

The index of the linestyle to be used for plot tickmarks and grids (i.e., when [XYZ]TICKLEN is set to 1.0). See LINESTYLE for a list of linestyles.

## [XYZ]MARGIN

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].MARGIN.

A 2-element array specifying the margin on the left (bottom) and right (top) sides of the plot window, in units of character size. Default margins are 10 and 3 for the X axis, and 4 and 2 for the Y axis. The ZMARGIN keyword is present for consistency and is currently ignored.

## [XYZ]MINOR

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].MINOR.

The number of minor tick mark intervals.

## [XYZ]RANGE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].RANGE.

The desired data range of the axis, a 2-element vector. The first element is the axis minimum, and the second is the maximum. IDL will frequently round this range. This override can be defeated using the [XYZ]STYLE keywords.

# [XYZ]STYLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].STYLE.

This keyword allows specification of axis options such as rounding of tick values and selection of a box axis. Each option is described in the following table:

| Value | Description |
|---|---|
| 1 | Force exact axis range. |
| 2 | Extend axis range. |
| 4 | Suppress entire axis |
| 8 | Suppress box style axis (i.e., draw axis on only one side of plot) |
| 16 | Inhibit setting the Y axis minimum value to 0 (Y axis only) |

*Table B-3: Values for the [XYZ]STYLE Keyword*

Note that this keyword is set bitwise, so multiple effects can be set by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the XAXIS keyword to `1+8`, or 9.

# [XYZ]THICK

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].THICK.

This keyword controls the thickness of the lines forming the axis and tick marks. A value of 1.0 is the default.

# [XYZ]TICK_GET

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE.

A named variable in which to return the values of the tick marks for the designated axis. The result is a double precision floating-point array with the same number of elements as ticks.

For example, to retrieve in the variable V the values of the tick marks selected by IDL for the Y axis:

```
PLOT, X, Y, YTICK_GET = V
```

# [XYZ]TICKFORMAT

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKFORMAT.

Set this keyword to a string or a vector of strings. If a vector is provided, each string corresponds to a level of the axis. The [XYZ]TICKUNITS keyword determines the number of levels for an axis.

Each string is one of the following:

## A format code:

If the string begins with an open parenthesis, it is treated as a standard format string. See "Format Codes" in Chapter 10 of the *Building IDL Applications* manual for more information on format codes.

**Example 1**: Display the X axis tick values using a format of F6.2 (six characters, with 2 places after the decimal point):

```
PLOT, X, Y, XTICKFORMAT='(F6.2)'
```

**Example 2**: Display the Y tick values using the "dollars and cents" format $*dddd.dd*:

```
PLOT, X, Y, YTICKFORMAT='("$", F7.2)'
```

## The string 'LABEL_DATE' :

Set [XYZ]TICKFORMAT to the string 'LABEL_DATE' to create axes with date labels. The formatting of the labels is specified by first calling LABEL_DATE with the DATE_FORMAT keyword. See LABEL_DATE for more information.

**Example**: Use the LABEL_DATE function as the callback function to display the X tick values in a date/time format:

```
dummy = LABEL_DATE(DATE_FORMAT='%M %Z')
mytimes = TIMEGEN(12, UNITS='MONTHS', START=JULDAY(1,1,2000))
y = FINDGEN(12)
PLOT, mytimes, y, XTICKUNITS='Time', XTICKFORMAT='LABEL_DATE'
```

## The name of a user-defined function:

If the string does not begin with an open parenthesis, it is interpreted as the name of a callback function to be used to generate tick mark labels. This function is defined with either three or four parameters, depending on whether [XYZ]TICKUNITS is specified:

If [XYZ]TICKUNITS is *not* specified, the callback function is called with three parameters, *Axis*, *Index*, and *Value*, where:

- *Axis* is the axis number: 0 for X axis, 1 for Y axis, 2 for Z axis.
- *Index* is the tick mark index (indices start at 0).
- *Value* is the data value at the tick mark (a double-precision floating point value).

**Note**

*Value* is a double-precision floating-point value that represents the Julian date. The Julian date follows the astronomical convention, where Julian date 0.0d corresponds to 1 Jan 4713 B.C.E. at 12 pm.

If [XYZ]TICKUNITS is specified, the callback function is called with four parameters, *Axis*, *Index*, *Value*, and *Level*, where:

- *Axis*, *Index*, and *Value* are the same as described above.
- *Level* is the index of the axis level for the current tick value to be labeled (level indices start at 0).

**Example 1**: Use a callback function to display the Y tick values as a percentage of a fixed value. Note that because we don't specify [XYZ]TICKUNITS, we do not include the *Level* parameter in our function definition:

```
FUNCTION YTICKS, axis, index, value
   fixvalue = 389.0d
   pvalue = (value/fixvalue) * 100.0d
   RETURN, STRING(pvalue, FORMAT='(D5.2,"%")')
END

PRO use_callback

   Y = FINDGEN(10)
   PLOT, Y, YTICKFORMAT='YTICKS'

END
```

**Example 2**: Create a two-level X axis. Display the X tick values in a customized date/time format that shows the number of days open for business for each month on one level, and marks leap years with an asterisk on another level:

```
FUNCTION XTICKS, axis, index, value, level

   CASE level OF
     0: BEGIN ; months
          ; Number of days open for business in given month:
```

```
            CALDAT, value, month
            open = [18,19,23,20,22,22,19,10,20,21,22,14]
            nbdays = open[month]
            ; Return a string containing the month name plus
            ; the number of business days in parentheses:
            RETURN, STRING(value, nbdays, $
               FORMAT='(C(CMoA), "(", I2, ")")')
         END
      1: BEGIN ; years
            ; Generate a string for the year.
            yrStr = STRING(value, FORMAT='(C(CYI))')
            ; Determine if a leap year.  If so,
            ; append an asterisk to the string.
            CALDAT, value, mo, da, yr
            IF (yr MOD 4 EQ 0) THEN BEGIN
               IF (yr MOD 100 EQ 0) THEN $
                  isLeap = (yr MOD 400) EQ 0 $
               ELSE $
                  IsLeap = 1b
            ENDIF ELSE $
            isLeap = 0b
            IF (isLeap NE 0b) THEN $
               yrStr = yrStr + '*'
               RETURN, yrStr
            END
      ENDCASE

END

PRO plot_sales

   myDates = TIMEGEN(12, UNITS='Months', START=JULDAY(1,1,2000))
   sales = [180,190,230,200,220,220,190,100,200,210,220,140]
   PLOT, myDates, sales, XTICKUNITS=['Months', 'Years'], $
      XTICKFORMAT='XTICKS', XTITLE = 'Date (* = Leap Year)', $

END
```

# [XYZ]TICKINTERVAL

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE

variable equivalent: ![XYZ].TICKINTERVAL

Set this keyword to a scalar indicating the interval between major tick marks for the first axis level. The default value is computed according to the axis range

([XYZ]RANGE) and the number of major tick intervals ([XYZ]TICKS). This keyword takes precedence over [XYZ]TICKS.

For example, if TICKUNITS=[“Seconds”, “Hours”, “Days”], and XTICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

# [XYZ]TICKLAYOUT

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKLAYOUT.

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

Valid values include:

- 0 = The axis line, major tick marks and tick labels are all included. Minor tick marks only appear on the first level of the axis. This is the default tick layout style.
- 1 = Only the labels for the major tick marks are drawn. The axis line, major tick marks, and minor tick marks are omitted.
- 2 = Each major tick interval is outlined by a box. The tick labels are positioned within that box (left-aligned). For the first axis level only, the major and minor tick marks will also be drawn.

**Note**

For all tick layout styles, at least one tick label will appear on each level of the axis (even if no major tick marks fall along the axis line). If there are no major tick marks, the single tick label will be centered along the axis.

# [XYZ]TICKLEN

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKLEN.

This keyword controls the lengths of tick marks (expressed in normal coordinates) for the individual axes. This keyword, if nonzero, overrides the global tick length specified in !P.TICKLEN, and/or the TICKLEN keyword parameter, which is expressed in terms of the window size.

# [XYZ]TICKNAME

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKNAME.

A string array of up to 30 elements that controls the annotation of each tick mark.

# [XYZ]TICKS

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKS.

The number of major tick *intervals* to draw for the axis. If this keyword is omitted, IDL selects from three to six tick intervals. Setting this field to *n*, where $n > 1$, produces exactly *n* tick intervals, and *n*+1 tick marks. Setting this field equal to 1 suppresses tick marks.

# [XYZ]TICKUNITS

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKUNITS.

Set this keyword to a string or a vector of strings indicating the units to be used for axis tick labeling. If a vector of strings is provided, the axis will be drawn in multiple levels, where each string represents one level in the specified units.

**Note**

When creating multiple-level axes, you may need to adjust the plot positioning using the POSITION or [XYZ]MARGIN keywords in order to ensure that axis labels and titles are visible in the plot window.

The order in which the strings appear in the vector determines the order in which the corresponding unit levels will be drawn. The first string corresponds to the first level (the level nearest to the primary axis line).

Valid unit strings include:

- 'Numeric'
- 'Years'
- 'Months'
- 'Days'
- 'Hours'

- 'Minutes'
- 'Seconds'
- 'Time' - Use this value to indicate that the tick values are time values; IDL will determine the appropriate time intervals and tick label formats based upon the range of values covered by the axis.
- "- Use the empty string to indicate that no tick units are being explicitly set. This implies that a single axis level will be drawn using the 'Numeric' unit. This is the default setting.

If any of the time units are utilized, the tick values are interpreted as Julian date/time values.

Note that the singular form of each of the time value strings is also acceptable (e.g, TICKUNITS='Day' is equivalent to TICKUNITS='Days').

**Note**

Julian values must be in the range -1095 to 1827933925, which corresponds to calendar dates 1 Jan 4716 B.C.E. and 31 Dec 5000000, respectively.

## [XYZ]TICKV

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TICKV.

The data values for each tick mark, an array of up to 60 elements.

**Note**

To specify the number of ticks and their values exactly, set [XYZ]TICKS=*N(where N > 1)* and [XYZ]TICKV=*Values*, where *Values* has *N*+1 elements.

## [XYZ]TITLE

Accepted by: AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE. System variable equivalent: ![XYZ].TITLE.

A string that contains a title for the specified axis.

## Z

Accepted by: PLOTS, POLYFILL, TV, TVCRS, XYOUTS.

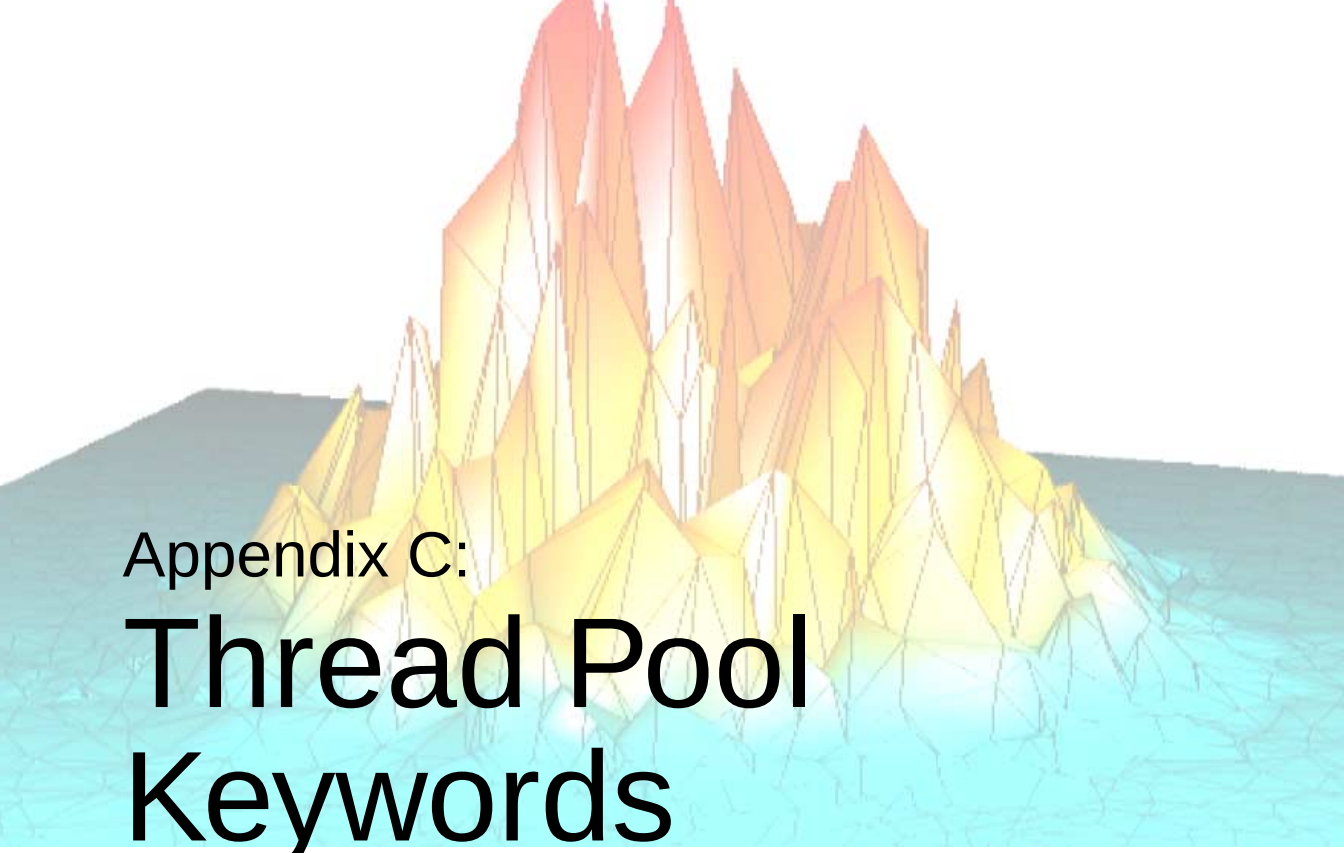
Provides the Z coordinate if a Z parameter is not present in the call. This is of use only if the three-dimensional transformation is in effect (i.e., the T3D keyword is set).

## ZVALUE

Accepted by: AXIS, CONTOUR, MAP_SET, OPLOT, PLOT, SHADE_SURF, SURFACE.

Sets the Z coordinate, in normalized coordinates in the range of 0 to 1, of the axis and data output from PLOT, OPLOT, and CONTOUR.

This keyword has effect only if !P.T3D is set and the three-dimensional to two-dimensional transformation is stored in !P.T. If ZVALUE is not specified, CONTOUR will output each contour at its Z coordinate, and the axes and title at a Z coordinate of 0.0.



# Appendix C: Thread Pool Keywords

Many of the system routines documented in this manual make use of the IDL thread pool. The thread pool is discussed in detail in Chapter 14, “Multithreading in IDL” in the *Building IDL Applications* manual. System-wide use of the thread pool can be controlled with the CPU procedure, and the current system settings are visible via the !CPU system variable.

All system routines that use the thread pool accept the following keywords, which can be used to modify the default behavior for the duration of a single call. This allows you to modify the settings for a particular computation without affecting the global default settings of the IDL session.

# Thread Pool Keywords

## TPOOL_MAX_ELTS

Set this keyword to a non-zero value to set the maximum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation exceeds the number you specify, IDL will not use the thread pool for the computation. Setting this value to 0 removes any limit on the maximum number of elements, and any computation with at least TPOOL_MIN_ELTS will use the thread pool.

This keyword overrides the default value, given by !CPU.TPOOL_MAX_ELTS. See "Possible Drawbacks to the Use of the IDL Thread Pool" in Chapter 14 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a maximum number of elements.

## TPOOL_MIN_ELTS

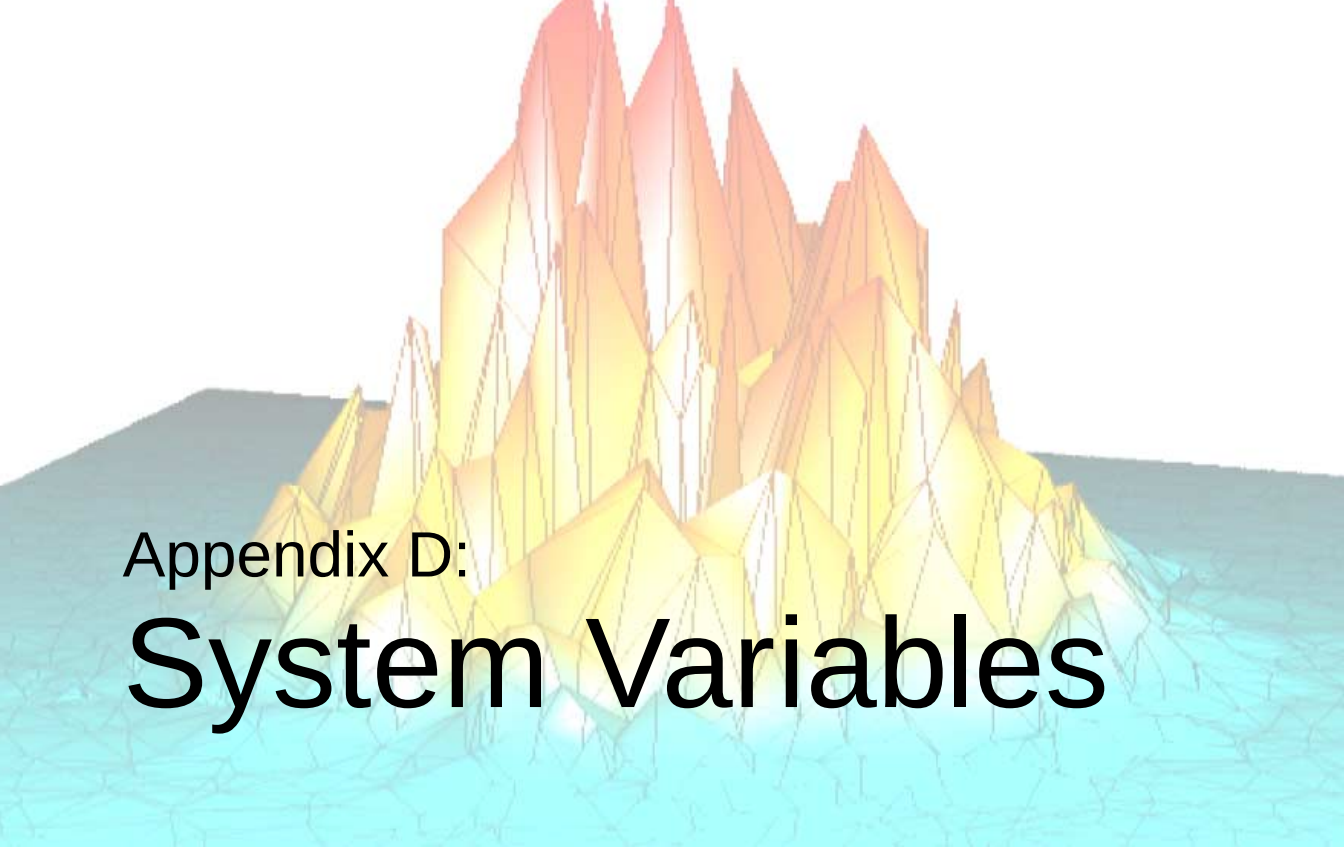
Set this keyword to a non-zero value to set the minimum number of data elements involved in a computation that uses the thread pool. If the number of elements in the computation is less than the number you specify, IDL will not use the thread pool for the computation. Use this keyword to prevent IDL from using the thread pool on tasks that are too small to benefit from it.

This keyword overrides the default value, given by !CPU.TPOOL_MIN_ELTS. See "Possible Drawbacks to the Use of the IDL Thread Pool" in Chapter 14 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to specify a minimum number of elements.

## TPOOL_NOTHREAD

Set this keyword to explicitly prevent IDL from using the thread pool for the current computation. If this keyword is set, IDL will use the non-threaded implementation of the routine even if the current settings of the !CPU system variable would allow use of the threaded implementation.

This keyword overrides the default value, given by !CPU.TPOOL_NTHREADS. See "Possible Drawbacks to the Use of the IDL Thread Pool" in Chapter 14 of the *Building IDL Applications* manual for discussion of the circumstances under which it may be useful to disable use of the thread pool entirely.



# Appendix D: System Variables

The following topics are included in this appendix:

# What Are System Variables?

System variables are a special class of predefined variables available to all program units. Their names always begin with the exclamation mark character (!). System variables are used to set the options for plotting, to set various internal modes, to return error status, etc.

System variables have a predefined type and structure that cannot be changed. When an expression is stored into a system variable, it is converted to the variable type, if necessary and possible. Certain system variables are *read only*, and their values cannot be changed. The user can define new system variables with the DEFSYSV procedure.

# Constant System Variables

The following system variables contain pre-defined constants or values for use by IDL routines. System variables can be used just like other variables. For example, the command:

```
PRINT, ACOS(A) * !RADEG
```

converts a result expressed in radians to one expressed in degrees.

## !DPI

A read-only variable containing the double-precision value of pi ($\pi$).

## !DTOR

A read-only variable containing the floating-point value used to convert degrees to radians ($\pi/180 \cong 0.01745$).

## !MAP

An array variable containing the information needed to effect coordinate conversions between points of latitude and longitude and map coordinates. The values in this array are established by the MAP_SET procedure; the user should not change them directly.

## !PI

A read-only variable containing the single-precision value of pi ($\pi$).

## !RADEG

A read-only variable containing the floating-point value used to convert radians to degrees ($180/\pi \cong 57.2958$).

## !VALUES

A read-only variable containing the IEEE single- and double-precision floating-point values *Infinity* and *NaN* (Not A Number). !VALUES is a structure variable with the following fields:

```
** Structure !VALUES, 4 tags, length=24:
   F_INFINITY      FLOAT          Infinity
   F_NAN           FLOAT               NaN
   D_INFINITY      DOUBLE         Infinity
   D_NAN           DOUBLE              NaN
```

where *Infinity* is the value Infinity and *NaN* is the value Not A Number. For more information on these special floating-point values, see "Special Floating-Point Values" in Chapter 18 of the *Building IDL Applications* manual.

# Error Handling System Variables

The following system variables are either set by IDL when an error condition occurs or used by IDL when displaying information about errors.

## !ERR

*This system variable is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !ERR system variable will continue to function as before, but all new code should use !ERROR_STATE.CODE.*

## !ERROR_STATE

A structure variable which contains the status of the last error message. !ERROR_STATE includes the following fields:

```
** Structure !ERROR_STATE, 8 tags, length=112, data length=108:
   NAME            STRING    'IDL_M_SUCCESS'
   BLOCK           STRING    'IDL_MBLK_CORE'
   CODE            LONG                 0
   SYS_CODE        LONG      Array[2]
   SYS_CODE_TYPE   STRING    ''
   MSG             STRING    ''
   SYS_MSG         STRING    ''
   MSG_PREFIX      STRING    '% '
```

- NAME: A read-only string variable containing the error name of the IDL-generated component of the last error message.
- BLOCK: A read-only string variable containing the name of the message block for the last error message's IDL-generated component.

  **Note**

  See the *External Development Guide* for more information about blocks.

- CODE: A long-integer variable containing the error code of the last error's IDL-generated component.
- SYS_CODE: A long-integer variable containing the error code of the last error's operating system-generated component, if it exists.

  For historical reasons, SYS_CODE is a two-element longword array. The first element of the array (that is, SYS_CODE[0]) contains the OS-defined error code. The second element of the array is not used, and always contains zero.

Either !ERROR_STATE.SYS_CODE or !ERROR_STATE.SYS_CODE[0] will return the relevant error code.

- SYS_CODE_TYPE: A string describing the type of system code contained in SYS_CODE. A null string in this field indicates that there is no system code corresponding to the current error. The possible non-NULL values are:

| Value | Meaning |
|---|---|
| errno | Unix/Posix system error |
| win32 | Microsoft Windows Win32 system error |
| winsock | Microsoft Windows sockets library error |

*Table D-1: SYS_COD_TYPE Values*

- MSG: A read-only string variable containing the text of the last IDL-generated error message.
- SYS_MSG: A read-only string variable containing the text of the last error's operating system-generated component, if it exists.
- MSG_PREFIX: A string variable containing the prefix string used for error messages.

This system variable replaces !ERROR, !ERR_STRING, !MSG_PREFIX, !SYSERR_STRING, and !SYSERROR, and includes two new fields: error name and block name. For a more detailed explanation of !ERROR_STATE, see "Error Handling" in Chapter 18 of the *Building IDL Applications* manual.

# !ERROR

*This system variable is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !ERROR system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.CODE.*

# !ERR_STRING

*This system variable is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !ERR_STRING system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.MSG.*

# !EXCEPT

An integer variable that controls when IDL checks for invalid mathematical computations (exceptions), such as division by zero. The three allowed values are:

| Value | Description |
|---|---|
| 0 | Never report exceptions. |
| 1 | Report exceptions when the interpreter is returning to an interactive prompt (the default). |
| 2 | Report exceptions at the end of each IDL statement. Note that this slows IDL by roughly 5% compared to setting !EXCEPT=1. |

*Table D-2: EXCEPT Values*

For more information on invalid mathematical computations and error reporting, see "Math Errors" in Chapter 18 of the *Building IDL Applications* manual.

The value of !EXCEPT is used by the CHECK_MATH function to determine when to return errors. See "CHECK_MATH" on page 226 for details.

**Note**

In versions of IDL up to and including IDL 4.0.1, the default exception handling was functionally identical to setting !EXCEPT=2.

# !MOUSE

A structure variable that contains the status from the last cursor read operation. !MOUSE has the following fields:

```
** Structure !MOUSE, 4 tags, length=16:
   X               LONG               511
   Y               LONG               252
   BUTTON          LONG                 4
   TIME            LONG        1428829775
```

- X and Y: Contain the location (in device coordinates) of the cursor when the mouse button was pressed.
- BUTTON: Contains
  - 1 (one) if the left mouse button was pressed,

- 2 (two) if the middle mouse button was pressed
- 4 (four) if the right mouse button was pressed.

- TIME: Contains the number of milliseconds since a base time.

See "CURSOR" on page 344 for details on reading the cursor position.

## !MSG_PREFIX

*This keyword is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !MSG_PREFIX system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.MSG_PREFIX.*

## !SYSERROR

*This keyword is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !SYSERROR system variable will continue to function as before, but we suggest that all new code use !ERROR_STATE.SYS_CODE.*

## !SYSERR_STRING

*This keyword is now obsolete and has been replaced by the !ERROR_STATE system variable. Code that uses the !*SYSERR_STRING *system variable will continue to function as before, but we suggest that all new code use !ERROR_*STATE.SYS_MSG*.*

## !WARN

A structure variable that causes IDL to print warnings to the console or command log when obsolete IDL features are found at compile time. !WARN has the following fields:

```
** Structure !WARN, 3 tags, length=3:
   OBS_ROUTINES         BYTE         0
   OBS_SYSVARS          BYTE         0
   PARENS               BYTE         0
```

Setting each of the three fields to 1 (one) generates a warning for a different type of obsolete code. If the OBS_ROUTINES field is set equal to one, IDL generates warnings when it encounters references to obsolete internal or library routines. If the OBS_SYSVARS field is set equal to one, IDL generates warnings when it encounters references to obsolete system variables. If the PARENS field is set equal to one, IDL generates warnings when it encounters a use of parentheses to specify an index into an array.

No warnings are generated when the fields of the !WARN structure are set equal to zero (the default).

# IDL Environment System Variables

The following system variables contain information about IDL's configuration.

## !CPU

IDL can use multiple system processors to perform some computations in parallel. See Chapter 14, "Multithreading in IDL" in the *Building IDL Applications* manual for additional information.

The !CPU system variable supplies information about the state of the system processor, and of IDL's use of it. !CPU is readonly, and cannot be modified directly. Use the CPU procedure to modify values contained in !CPU.

The !CPU structure is defined as follows:

```
{ !CPU, HW_VECTOR:0L, VECTOR_ENABLE:0L, HW_NCPU:0L,
  TPOOL_NTHREADS:0L, TPOOL_MIN_ELTS:0L, TPOOL_MAX_ELTS:0L }
```

The meaning of the fields of !CPU are given in the following table.!

| Field | Meaning |
|---|---|
| HW_VECTOR | True (1) if the system supports a vector unit (e.g. Macintosh Altivec/Velocity Engine). False (0) otherwise.<br>**Note -** This value is currently always 0 (False) on platforms other than Macintosh. |
| VECTOR_ENABLE | True (1) if IDL will use a vector unit, if such a unit is available on the current system, and False (0) otherwise.<br>**Note -** This value is currently always 0 (False) on platforms other than Macintosh. |
| HW_NCPU | The number of CPUs contained in the system on which IDL is currently running. |

*Table D-3: Meaning of !CPU fields*

| Field | Meaning |
|---|---|
| TPOOL_NTHREADS | The number of threads that IDL will use in thread pool computations. The default is to use HW_NCPU threads, so that each thread will have the potential to run in parallel with the others. For numerical computation, there is no benefit to using more threads than your system has CPUs. However, depending on the size of the problem and the number of other programs running on the system, there may be a performance advantage to using fewer CPUs. |
| TPOOL_MIN_ELTS | The number of elements in a computation that are necessary before IDL will use the thread pool to perform the work. For fewer than TPOOL_MIN_ELTS, the main IDL thread will simply perform the work without using the thread pool. It is important not to use the thread pool for small tasks because the overhead of threading will not be offset by the overhead incurred by operation of the pool, and the overall computation will go slower than if threading is not used. |
| TPOOL_MAX_ELTS | The maximum number of elements in a computation for which IDL will use the thread pool. If this value is 0 (zero) (the default), then no limit is imposed and any computation with at least TPOOL_MIN_ELTS is a candidate for the thread pool. If your computation is too large for the physical memory available on the system, the virtual memory system of the operating system will begin paging. Under such conditions, the performance of the thread pool can be worse than that of a single threaded computation because the threads end up fighting each other for access to memory. TPOOL_MAX_ELTS can be used to prevent this. |

*Table D-3: Meaning of !CPU fields (Continued)*

## !DIR

A string variable containing the path to the main IDL directory.

# !DLM_PATH

Significant portions of IDL's built in functionality are packaged in the form of Dynamically Loadable Modules (DLMs). DLMs correspond to UNIX sharable libraries or Windows DLLs, depending on the operating system in use. At startup, IDL searches for DLM definition files (which end in the `.dlm` suffix) and makes note of the routines supplied by each DLM. If such are routine is called, IDL loads the DLM that supplies it into memory. To see a list of the DLMs that IDL knows about, use `HELP, /DLM` (see "HELP" on page 800 for more information).

!DLM_PATH is initialized from the environment variable IDL_DLM_PATH at startup. This initialization is similar to that performed for IDL_PATH, (see "!PATH" on page 3909), including recursive path expansion denoted with a leading "+" but *not* including any use of IDLDE preferences settings. See "Environment Variables Used by IDL" in Chapter 1 of the *Using IDL* manual for details on setting the IDL_DLM_PATH environment variable.

If the IDL_DLM_PATH environment variable is not defined, IDL supplies a default that contains the directory in the IDL distribution where the DLMs supplied by RSI reside. Once !DLM_PATH is expanded, IDL uses it as the list of places to look for DLM definition files.

Since all DLM searching happens once at startup time, it would be meaningless to change the value of !DLM_PATH afterwards. For this reason, it is a read-only system variable and cannot be assigned to. The value of !DLM_PATH is useful because it shows you where IDL looked for DLMs when it started.

## Using Path Definition Tokens to Load a DLM Path

Note that using the `<IDL_BIN_DIRNAME>` token in the IDL_DLM_PATH environment variable can be useful for distributing packages of DLMs with support for multiple operating system and hardware combinations. This token is described in "The Path Definition String" under EXPAND_PATH.

For example, assume that you have your DLMs installed in `/usr/local/mydlm`, with support for each platform in a subdirectory using the same naming convention that IDL uses for the platform dependant subdirectories underneath the bin directory of the IDL distribution. The following line, which might be located in a file executed by a UNIX shell when you log in (`.cshrc`, `.login`), will add the location of the proper DLM for your current system to IDL's !DLM_PATH at startup:

```
% setenv IDL_DLM_PATH
"/usr/local/mydlm/<IDL_BIN_DIRNAME>:<IDL_DEFAULT>"
```

(all on a single line). Setting the Windows environment variable IDL_DLM_PATH to a similar string would produce the same result on a Windows system.

Similarly, the `<IDL_VERSION_DIRNAME>` token can be useful for distributing packages of DLMs with support for multiple IDL versions, operating systems, and hardware platforms. This token is described in "The Path Definition String" under EXPAND_PATH.

For example, assume that you have your DLMs installed in `/usr/local/mydlm`. Within the `mydlm` subdirectory would be a directory for each supported version of IDL. Within each of those subdirectories would be a subdirectory for each operating system and hardware combination supported by that version of IDL. The following line, which might be located in a file executed by your shell when you log in (`.cshrc`, `.login`) will add the location of the proper DLM for your current system to IDL's !DLM_PATH at startup:

```
% setenv IDL_DLM_PATH
"/usr/local/mydlm/<IDL_VERSION_DIRNAME>/<IDL_BIN_DIRNAME>:<IDL_DEFAULT>"
```

(all on a single line). Setting the Windows environment variable IDL_DLM_PATH to a similar string would produce the same result on a Windows system.

## !EDIT_INPUT

An integer variable indicating whether keyboard line editing is enabled (when set to a non-zero value) or disabled (when set to zero). By default, !EDIT_INPUT is set equal to one, and line editing is enabled.

By default, IDL saves the last 20 command lines. You can change the number of command lines saved in the recall buffer by setting !EDIT_INPUT equal to the number of lines you would like to save. In order for the change to take effect, IDL must be able to process the assignment statement before providing a command prompt. This means that you must put the assignment statement in the IDL startup file. (See "Startup Files" in Chapter 1 of the *Using IDL* manual for more information on startup files.)

## !HELP_PATH

A string variable listing the directories IDL will search for online help files. On UNIX systems, help files must be Adobe Portable Document Format (`.pdf`) files or HTML (`.html` or `.htm`) files. On Windows systems, help files can be HTML Help (`.chm`), Windows Help (`.hlp`), Portable Document Format (`.pdf`), or HTML (`.html` or `.htm`) files.

!HELP_PATH is initialized from the environment variable IDL_HELP_PATH at startup. This initialization is similar to that performed for IDL_PATH (see "!PATH" on page 3909), including recursive path expansion denoted with a leading "+" but *not* including any use of IDLDE preferences settings. See "Environment Variables Used by IDL" in Chapter 1 of the *Using IDL* manual for details on setting the IDL_HELP_PATH environment variable

If the IDL_HELP_PATH environment variable is not defined, IDL supplies a default that contains the directory in the IDL distribution where the help files supplied by RSI reside.

To change the value of !HELP_PATH for the duration of an IDL session, simply set the variable equal to a new string containing the desired path. See "Changing the Value of !PATH After IDL Starts" on page 3910 for tips that also apply to setting the value of !HELP_PATH.

# !JOURNAL

A read-only long-integer variable containing the logical unit number of the file used for journal output.

# !MAKE_DLL

The MAKE_DLL procedure and the CALL_EXTERNAL function's AUTO_GLUE keyword use the standard system C compiler and linker to generate sharable libraries that can be used by IDL in various contexts (CALL_EXTERNAL, DLMs, LINKIMAGE). There is a great deal of variation possible in the use of these tools between different platforms, operating system versions, and compiler releases. The !MAKE_DLL system variable is used to configure how IDL uses them for the current platform.

The !MAKE_DLL structure is defined as follows:

```
{ !MAKE_DLL, COMPILE_DIRECTORY:'', COMPILER_NAME:'', CC:'', LD:''}
```

The meaning of the fields of !MAKE_DLL are given in the following table. When expanding !MAKE_DLL.CC and !MAKE_DLL.LD, IDL substitutes text in place of the PRINTF style codes described in the following table. These codes are case-insensitive, and can be either upper or lower case.

It is possible to use C compilers other than the one assumed by RSI in !MAKE_DLL to build sharable libraries. To do so, you can alter the contents of !MAKE_DLL or use the CC and/or LD keyword to MAKE_DLL and CALL_EXTERNAL. Please understand that RSI cannot and does not maintain a list of all possible compilers and the necessary compiler options. This information is available in your compiler and

system documentation. It is the programmers responsibility to understand the rules for their chosen compiler.

| Field | Meaning |
|---|---|
| COMPILE_DIRECTORY | IDL requires a place to create the intermediate files necessary to build a sharable library, and possibly the final library itself. Unless told to use an explicit directory, it uses the directory given by the COMPILE_DIRECTORY field of !MAKE_DLL. If the IDL_MAKE_DLL_COMPILE_DIRECTORY environment variable is set, IDL uses its value to initialize the COMPILE_DIRECTORY field. Otherwise, IDL supplies a standard location.<br>**Note -** If the directory given by !MAKE_DLL.COMPILE_DIRECTORY does not exist when IDL needs it, IDL automatically creates it for you if possible. |
| COMPILER_NAME | A string containing the name of the C compiler used by RSI to build the currently running IDL. This field is not used by IDL, and exists solely for informational purposes and to help the end user decide which C compiler to install on their system. |
| CC | A string used by IDL as a template to construct the command for using the C compiler. This template uses PRINTF style substitution codes, as described in the following table. |
| LD | A string used by IDL as a template to construct the command for using the linker. This template uses PRINTF style substitution codes, as described in the following table. |

*Table D-4: Meaning of !MAKE_DLL Fields*

The following table describes the substitution codes for the CC and LD fields:

| Code | Meaning |
|---|---|
| %B %b | The base name of a C file to compile. For example, if the C file is `moose.c`, then %B substitutes `moose`. |
| %C %c | The name of the C file. |
| %E %e | The name of the linker options file. This file, which is automatically generated by IDL as needed, is used to control the linker. Under UNIX, the system documentation refers to this as an export file, or a linker map file. Microsoft Windows calls it a `.DEF` file. |
| %F %f | This substitution code is no longer meaningful, and will be ignored. |
| %L %l | The name of the resulting sharable library. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform (`.dll`, `.so`, `.sl`, `.exe`, ...). |
| %O %o | An object file name. IDL constructs this name by using the base name (%B) and adding the appropriate suffix for the current platform (`.o`, `.obj`). |
| %X %x | When expanding !MAKE_DLL.CC, any text supplied via the EXTRA_CFLAGS keyword to MAKE_DLL or CALL_EXTERNAL is inserted in place of %X. IDL does not interpret this text. It is the users responsibility to ensure that it is meaningful in the command. When expanding !MAKE_DLL.LD, the text from the EXTRA_LFLAGS keyword is substituted. The primary use for this code is to include necessary header include directories and link libraries. |
| %% | Replaced with a single % character. |

*Table D-5: Description of CC and LD Field Codes*

# !MORE

An integer variable indicating whether IDL should paginate help output sent to a tty device. Setting !MORE to zero (0) prevents IDL from paginating the output text. A non-zero value (the default) causes IDL to display output text one screen at a time.

# !PATH

A string variable listing the directories IDL will search for libraries, include files, and executive commands.

**Note**

The current directory is always searched before consulting !PATH.

!PATH is initialized from the environment variable IDL_PATH when IDL starts. See "Environment Variables Used by IDL" in Chapter 1 of the *Using IDL* manual for details on setting the IDL_PATH environment variable.

**Note**

If the IDL_PATH environment variable does not exist, IDL uses the value set in the **Path** tab of the **Preferences** dialog of the IDLDE. If no preference value is set, or if you are using the UNIX command-line interface rather than the IDLDE, IDL uses a default value in order to initialize !PATH.

## Note on Path Expansion

When IDL starts, it reads the IDL_PATH environment variable (or the default value, if IDL_PATH does not exist) and builds a value to be stored in !PATH from the specified initialization value. While the initialization value can consist of a normal path string specifying all directories to be included in !PATH, it can also take advantage of several special values that IDL uses to dynamically create the value of !PATH. These values (the "+" symbol and the "<IDL_*>" strings) are described in detail in "The Path Definition String" under "EXPAND_PATH" in the *IDL Reference Guide* manual.

## Path Caching

By default, as IDL searches directories included in the !PATH system variable for `.pro` or `.sav` files to compile, it creates an in-memory list of *all* `.pro` and `.sav` files contained in each directory. When IDL later searches for a `.pro` or `.sav` file, before attempting to open the file in a given directory, IDL checks the path cache to determine whether the directory has already been cached. If the directory is included in the cache, IDL uses the cached information to determine whether the file will be found in that directory, and will only attempt to open the file there if the cache tells it that the file exists. By eliminating unnecessary attempts to open files, the path cache speeds the path searching process. See "PATH_CACHE" in the *IDL Reference Guide* manual for details.

### Changing the Value of !PATH After IDL Starts

Once IDL has started, you can alter the value of !PATH by setting it to a new string value. For example, on a UNIX system, to add a directory to !PATH for the duration of an IDL session, you would use a command like the following:

```
!PATH = '/usr2/project/idl_files:' + !PATH
```

Keep the following in mind when changing the value of !PATH by setting its value to a new string:

- Remember to use the proper path string separator character for your platform. If you are writing a cross-platform application that changes !PATH, you may want to use code that looks something like this:

  ```
  pathsep = PATH_SEP(/SEARCH_PATH)
  !PATH = 'new_path' + pathsep + !PATH
  ```

  where *new_path* is the path to the directory you want to add.

- You can use the EXPAND_PATH function to generate a path string. This method allows you to specify one or more directories and let IDL figure out whether those directories contain `.pro` or `.sav` files. It also allows you to use the "+" character path expansion technique. For example, the following commands add all directories below the *new_path* directory that contain `.pro` or `.sav` files to !PATH:

  ```
  pathsep = PATH_SEP(/SEARCH_PATH)
  !PATH = EXPAND_PATH('+new_path') + pathsep + !PATH
  ```

  See "EXPAND_PATH" in the *IDL Reference Guide* manual for details.

## !PROMPT

A string variable containing the text string used by IDL to prompt the user for input. The default is `IDL>`.

## !QUIET

A long-integer variable indicating whether informational messages should be printed (0) or suppressed (nonzero). By default, !QUIET is set to zero.

## !VERSION

A structure variable containing information about the version of IDL in use. The structure is defined as follows:

```
{ !VERSION, ARCH:'', OS:'', OS_FAMILY:'', OS_NAME:'', $
   RELEASE:'', BUILD_DATE:'', MEMORY_BITS:0, FILE_OFFSET_BITS:0 }
```

The meaning of the fields of !VERSION are given in the following table.

| Field | Meaning |
|---|---|
| ARCH | CPU hardware architecture of the system. |
| OS | The vendor name of the operating system (for example: AIX, HP-UX, IRIX, linux, MacOS, OSF, sunos, Win32). This is the name of the underlying operating system kernel (not necessarily of the overall operating environment: see OS_NAME). Once an OS name is assigned to a platform by RSI, it is not altered in subsequent releases. This makes it safe for use in IDL programs that need to distinguish between platforms. RSI recommends that you first consider using the OS_FAMILY field before using the OS field, as most programs are mainly concerned with high level platform differences. |
| OS_FAMILY | The generic name of the operating system (UNIX, Windows). RSI recommends that whenever possible this field (rather than OS or OS_NAME) be used in code that must distinguish between platforms. |
| OS_NAME | The vendor's name for the operating system environment, as used by the vendor for casual descriptive and promotional purposes. For example, on Sun workstations, the name of the operating system kernel (!VERSION.OS) is "sunos", whereas the name of the overall system (!VERSION.OS_NAME) is "Solaris". Vendors change their descriptive environment names from time to time, and RSI updates the OS_NAME field to reflect this. As a result, RSI recommends that IDL users restrict their use of this field to descriptive textual uses, and that the OS_FAMILY or OS fields of !VERSION be used in code that must distinguish between platforms. |
| RELEASE | IDL version number. |

*Table D-6: Meaning of the !VERSION Fields*

| Field | Meaning |
|---|---|
| BUILD_DATE | The date the IDL executable was compiled, in the format dictated by ANSI C for the `__DATE__` macro. |
| MEMORY_BITS | The number of bits used to address memory. Possible values are 32 or 64. The number of bits used to address memory places a theoretical upper limit on the amount of memory available to IDL. |
| FILE_OFFSET_BITS | The number of bits used to position file offsets. Possible values are 32 or 64. The number of bits used to position files places a theoretical upper limit on the largest file IDL can access. |

*Table D-6: Meaning of the !VERSION Fields*

If you need to differentiate between different IDL versions in your code, use !VERSION.OS_FAMILY. At present, two operating system families are supported: UNIX and Windows. For even more detail, you can use !VERSION.OS.

# Graphics System Variables

The following system variables control various IDL Direct Graphics functions. These system variables are structures that contain many tags. For example, the command

```
!P.TITLE = 'Cross Section'
```

sets the default plot title.

Many of the functions of the graphics keywords described in Appendix B, “Graphics Keywords”, are also controlled by the system variables !P, !X, !Y, and !Z.

You can change the default style of plots, fonts, etc., by setting the corresponding field in the appropriate system variable. Also, some effects that persist longer than one call are controlled only by system variables. The field !P.MULTI is one example.

## !C System Variable

The cursor system variable. Currently, the only function of this system variable is to contain the subscript of the largest or smallest element found by the MAX and MIN functions. That information is better obtained through the optional output arguments to those routines. !C is included only for compatibility with old versions of IDL.

## !D System Variable

This system variable is a structure that contains information about the current graphics output device (or window, on a windowing system). Fields, in alphabetical order, are:

### FILL_DIST

The line interval, in device coordinates, required to obtain a solid fill.

## FLAGS

A longword of flags that provide information about the current device. Each bit is a flag encoded as shown in the following table.

| Bit | Value | Function |
|---|---|---|
| 0 | 1 | Device has scalable pixel size (e.g., PostScript). |
| 1 | 2 | Device can output text at an arbitrary angle using hardware. |
| 2 | 4 | Device can control line thickness with hardware. |
| 3 | 8 | Device can display images. |
| 4 | 16 | Device supports color. |
| 5 | 32 | Device supports polygon filling with hardware. |
| 6 | 64 | Device hardware characters are monospace. |
| 7 | 128 | Device can read pixels (i.e., it supports TVRD). |
| 8 | 256 | Device supports windows. |
| 9 | 512 | Device prints black on a white background (e.g., printers are plotters). |
| 10 | 1024 | Device has *no* hardware characters. |
| 11 | 2048 | Device does line-fill style polygon filling in hardware. |
| 12 | 4096 | Device will apply Hershey-style embedded formatting commands to device fonts. |
| 13 | 8192 | Device is a pen plotter. |
| 14 | 16384 | Device can transfer 16-bit pixels. |
| 15 | 32768 | Device supports Kanji characters. |
| 16 | 65536 | Device supports widgets. |
| 17 | 131072 | Device has Z-buffer. |
| 18 | 262144 | Device supports TrueType fonts. |

*Table D-7: !D.FLAGS Bit Definitions*

To test whether a particular bit is set on your system, use an IDL command like the following:

```
IF (!D.FLAGS AND value) NE 0 THEN PRINT, 'Bit is set.'
```

where value is the value associated with the bit you wish to examine. For example, to check whether the device supports color, use:

```
IF (!D.FLAGS AND 16) NE 0 THEN PRINT, 'Bit is set.'
```

## N_COLORS

The number of allowed color values. In the case of devices with windows, this field is set after the window system is initialized. For a monochrome system, !D.N_COLORS is 2. For TrueColor displays, !D.N_COLORS is 2^24-1 (roughly 16.7 million colors).

## NAME

A string containing the name of the device.

## ORIGIN

A two-element integer array containing the current pan/scroll offset. An offset of (0, 0) is normal. Positive offsets shift the display memory to the right and upwards. This field has relevance only with devices with hardware pan and scroll abilities.

## TABLE_SIZE

The number of color table indices.

**Note**

For TrueColor visuals, !D.TABLE_SIZE will always be 256. If the visual depth is less than 24 bits, IDL emulates 256 entries.

## UNIT

The logical number of the file open for output by the current graphics device. This field only has meaning for devices that write to a file if the file is accessible to the user from IDL, and is 0 if no file is open.

For example, the PostScript driver fills this field with the unit number of the file open for PostScript output. In the case of Tektronix output to a file, !D.UNIT may be set to either + or – the logical unit number.

## WINDOW

The index of the currently open window. This field is set to -1 if no window is currently open. This field is used only with devices that support windows.

## X_CH_SIZE, Y_CH_SIZE

The width and height of the rectangle that encloses the “average” character in the current font, in device units (usually pixels).

These values describe the size of the rectangle that contains the “average” character in the current font. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The first element specifies the width of the rectangle in device units (usually pixels), and the second element specifies the height.

For vector and TrueType fonts, the height of the “average” character is determined by the *width* of the rectangle. The aspect ratio of the “average” character remains fixed; the character is scaled so that its width is the value of X_CH_SIZE. The resulting scale factor is then applied to all of the characters in the font. The amount of spacing between lines is determined explicitly by the value of Y_CH_SIZE.

For device fonts, the character size is fixed. When the device font system is in use, the value of X_CH_SIZE is silently ignored, and only the Y_CH_SIZE value is used.

## X_PX_CM, Y_PX_CM

The approximate number of pixels per centimeter in the X and Y directions.

## X_SIZE, Y_SIZE

The total size of the display or window in the X and Y directions, in device units.

## X_VSIZE, Y_VSIZE

The size of the visible area of the display or window. This area can be smaller than the total size fields.

## ZOOM

This field contains the current X and Y zoom factors for the display or window. This field has relevance only with devices equipped with hardware zoom. A zoom factor of [1, 1] is normal.

# !ORDER System Variable

Controls the direction of image transfers when using the TV, TVSCL, and TVRD procedures. If !ORDER is 0, images are transferred from bottom to top, i.e. the row with a 0 subscript is written on the bottom. Setting !ORDER to 1, transfers images from top to bottom.

# !P System Variable

The main plotting system variable structure. All fields, except !P.MULTI, have a directly corresponding keyword parameter in the plot procedures: PLOT, OPLOT, CONTOUR, and SURFACE. Fields, in alphabetical order, are:

## BACKGROUND

The background color index. When erasing the screen or page, all pixels are set to this color. The default value is 0. Not all devices support this feature.

## CHANNEL

The default source or destination channel. This field has meaning only on graphics devices that contain multiple display channels, and is device dependent. It may contain either a channel mask or index.

## CHARSIZE

The overall character size of all annotations when Hershey fonts are selected. This field has no effect on the character size when hardware (device) fonts are selected, except for devices that support scalable pixel sizes (i.e., Postscript). Note, however, that !P.CHARSIZE always affects the layout and scaling of a plot, regardless of the font system being used. The default size is 1.0.

## CHARTHICK

An integer specifying the thickness of the lines used to draw the characters when using the vector drawn fonts. This field has no effect on the appearance of characters drawn with the hardware fonts. Normal thickness is 1.

## CLIP

The device coordinates of the clipping window, a 6-element vector of the form $[x_0, y_0, x_1, y_1, z_0, z_1]$, specifying two opposite corners of the volume to be displayed. In the case of two-dimensional displays, the Z coordinates can be omitted. Normally, the clipping window coordinates are implicitly set by PLOT, CONTOUR,

SHADE_SURF, and SURFACE to correspond to the plot window. You may also manually set !P.CLIP if you want to specify a different rectangular clipping window or if the clipping coordinates have not yet been set in the current IDL session.

## COLOR

The default color index.

## FONT

An integer that specifies the graphics text font system to use. Set FONT equal to -1 to selects the Hershey character fonts, which are drawn using vectors. Set FONT equal to 0 (zero) to select the device font of the output device. Set FONT equal to 1 (one) to select the TrueType font system. See Appendix H, “Fonts”, for a complete description of IDL’s font systems.

## LINESTYLE

The default style of the lines used to connect points. A line style index of 0 yields a solid line. See “LINESTYLE” on page 3875 for a description of the linestyles.

## MULTI

!P.MULTI allows making multiple plots on a page or screen. It is a 5-element integer array defined as follows:

!P.MULTI[0] contains the number of plots remaining on the page. If !P.MULTI[0] is less than or equal to 0, the page is cleared, the next plot is placed in the upper left hand corner, and !P.MULTI[0] is reset to the number of plots per page.

Setting !P.MULTI[0] to a value greater than zero can be used to manually set the plotting area to a specific row and column. For example, to plot in the lower left corner of a window of two rows and two columns, set !P.MULTI as follows:

```
!P.MULTI=[2,2,2]
PLOT, X, Y
```

!P.MULTI[1] is the number of plot columns per page. If this value is less than or equal to 0, one is assumed. If more than two plots are ganged in either the X or Y direction, the character size is halved.

!P.MULTI[2] is the number of rows of plots per page. If this value is less than or equal to 0, one is assumed.

!P.MULTI[3] contains the number of plots stacked in the Z dimension.

!P.MULTI[4] is 0 to make plots from left to right (column major), and top to bottom, and is 1 to make plots from top to bottom, left to right (row major).

**Note**

If !P.MULTI[0] is zero, an erase will occur before the current plot is displayed (unless the /NOERASE keyword is set). This is true no matter whether !P.POSITION and/or !P.REGION are set.

For example, to gang two plots across the page:

```
!P.MULTI = [0, 2, 0, 0, 0]
PLOT, X0, Y0                    ;Make left plot.
PLOT, X1, Y1                    ;Right plot.
```

To gang two plots vertically:

```
!P.MULTI = [0, 0, 2, 0, 0]
PLOT, X0, Y0                    ;Make top plot.
PLOT, X1, Y1                    ;Bottom plot.
```

To make four plots per page, two across and two up and down:

```
!P.MULTI = [0, 2, 2, 0, 0]
```

and then call plot four times.

To reset !P.MULTI back to the normal one plot per page:

```
!P.MULTI = 0
```

## NOCLIP

A field which, if set, inhibits the clipping of the graphic vectors and vector-drawn text. By default, most routines clip to the plotting window, with the exception of PLOTS and XYOUTS. !P.CLIP contains the clipping rectangle.

## NOERASE

Set this field to a non-zero value to inhibit erasing the screen before plotting.

## NSUM

The number of adjacent points to average to obtain a plotted point.

## POSITION

Specifies the normalized coordinates of the rectangular plot window. This is a four element floating point vector $(x_0, y_0, x_1, y_1)$, where $(x_0, y_0)$ is the origin, and $(x_1, y_1)$ is the upper right corner.

!P.POSITION determines the plotting window if $x_0$ does not equal $x_1$, and the POSITION keyword is not present. If set, it overrides the effect of the MARGIN and !P.MULTI variables and keywords.

**Note**

If !P.POSITION (or the POSITION keyword) or !P.REGION is set, all but the first element of !P.MULTI are ignored.

## PSYM

The default plotting symbol index. Each point drawn by PLOT, PLOTS, and OPLOT is marked with a symbol if this field is non-zero. The possible symbols are given in "PSYM" on page 3878.

## REGION

A four element vector that specifies the normalized coordinates of the rectangle enclosing the plot region, which includes the plot data window and its surrounding annotation area. It is in the same form as !P.POSITION, $(x_0, y_0, x_1, y_1)$, where $(x_0, y_0)$ is the origin, and $(x_1, y_1)$ is the upper right corner. It is ignored if !P.REGION[0] is equal to !P.REGION[2].

**Note**

!P.POSITION (or the POSITION keyword) takes precedence over !P.REGION.

## SUBTITLE

The plot subtitle, placed under the X axis label.

## T

Contains the homogeneous 4 x 4 transformation matrix. This field is a two-dimensional array of double-precision floating-point values. For more information about transformations, refer to "Three-Dimensional Graphics" in Chapter 18 of the *Using IDL* manual.

## T3D

Enables the three-dimensional to two-dimensional transformation contained in the homogeneous 4 by 4 matrix !P.T. Note that if T3D is set, !P.T must contain a valid transformation matrix.

### THICK

The thickness of the lines connecting points. 1.0 is normal.

### TITLE

The main plot title.

### TICKLEN

The length of the tick marks, expressed as a fraction of the plot size (from 0.0 to 1.0). The default is 0.02. A value of 0.5 makes a grid. Negative values make the tick marks point outward.

## !X, !Y, !Z System Variables

The system variables !X, !Y, and !Z, are structures of type AXIS, that affect the appearance and scaling of the three axes. The fields for !X, !Y, and !Z have identical fields with identical meanings and usage. In addition, almost all fields have corresponding keyword parameters, with identical function, but with temporary effect. For example, to suppress the minor tick marks on the X axis using the !X system variable, you could use the command:

```
!X.MINOR = -1
```

To suppress the tick marks for just one call to plot, you could use the command:

```
PLOT, X, Y, XMINOR = -1
```

The name of the keyword parameter is simply the name of the system variable field, prefixed with the letter X, Y, or Z.

The fields for these system variables, in alphabetical order are:

### CHARSIZE

The size of the characters used to annotate the axis and its title when Hershey fonts are selected. This field has no meaning when hardware (i.e. PostScript) fonts are selected. This field is a scale factor applied to the global scale factor. For example, setting !P.CHARSIZE to 2.0, and !X.CHARSIZE to 0.5 results in a character size of 1.0 for the X axis.

### CRANGE

The output axis range. Setting this variable has no effect; set ![XYZ].RANGE to change the range. ![XYZ].CRANGE[0]) always contains the minimum axis value,

and ![XYZ].CRANGE[1] contains the maximum axis value of the last plot before extending the axes.

**Note**

If the axis is logarithmic, the CRANGE field reports the log (base 10) of the minimum and maximum axis values.

Example 1:

```
;Create a 10-element array.
a = INDGEN(10)

;Plot the straight line.
PLOT, a

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE
```

IDL prints:

```
0.00000      10.0000
```

Example 2:

```
;Plot a with logarithmic scaling on the X axis.
PLOT, a, /XLOG

;Print the minimum and maximum axis values.
PRINT, !X.CRANGE
```

The axis is scaled from $10^{-12}$ to $10^{2}$. IDL prints:

```
-12.0000      2.00000
```

## GRIDSTYLE

The index of the linestyle to be used for tick marks and grids. See “LINESTYLE” on page 3875 for a description of the linestyles

## MARGIN

A 2-element array specifying the margin on the left (bottom) and right (top) sides of the plot window, in units of character size. The plot window is the rectangular area that contains the plot data, i.e. the area enclosed by the axes.

The default values for !X.MARGIN are [10, 3] yielding a 10-character wide left margin and a 3-character wide right margin. The values for !Y.MARGIN are [4, 2], for a 4-character high bottom margin and a 2-character high top margin. While specifying !Z.MARGIN will not cause an error, Z margins are currently ignored.

When calculating the size and position of the plot window, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting !P.POSITION, or specification of the POSITION parameter overrides the effect of this field.

## MINOR

The number of minor tick mark intervals. If !X.MINOR is 0, the default, the number of minor tick intervals is automatically determined from the tick mark increment. You can force a given number of minor tick intervals by setting this field to the desired number. To suppress minor tick marks, set !X.MINOR to -1.

## OMARGIN

A 2-element array specifying the “outer” margin on the left (bottom) and right (top) sides of a multi-plot window, in units of character size. A multi-plot window is created by setting the !P.MULTI system variable field. OMARGIN controls the amount of space around the entire plot area, including individual plot margins set with !X.MARGIN and !Y.MARGIN. The default values for !X.OMARGIN and !Y.OMARGIN are [0, 0].

When calculating the size and position of the individual plots, IDL first determines the plot region, the area enclosing the window plus the axis annotation and titles. It then subtracts the appropriate margin from each side, obtaining the window.

Setting !P.POSITION, or specification of the POSITION parameter overrides the effect of this field.

## RANGE

The input axis range, a 2-element vector. The first element is the axis minimum, and the second is the maximum. Set this field, or use the corresponding keyword parameter, to specify the data range to plot. If axis end point rounding is selected (see STYLE above), the final axis range may not be equal to this input range. The field !X.CRANGE contains the axis range used for the plot before extending the axes. Set both elements equal to 0 for automatic axis ranges:

```
!X.RANGE = 0
```

For example, to force the X axis to run from 5.5 to 8.3:

```
!X.RANGE = [5.5, 8.3]
PLOT, X, Y
```

Alternatively, by using keywords:

```
PLOT, X, Y, XRANGE=[5.5, 8.3]
```

Note that even though the range was set to (5.5, 8.3), the resulting plot has a range of (5.5, 8.5), because axis rounding is the default.

## REGION

Contains the normalized coordinates of the region. This field is similar to WINDOW, in that it is set by the graphics procedures and is a 2-element floating point array. To change the default plotting region, set !P.REGION.

## S

The scaling factors for converting between data coordinates and normalized coordinates (a 2-element array). The formula for conversion from data ($X_d$) to normalized ($X_n$) coordinates is $X_n = S_1 X_d + S_0$

If logarithmic scaling is in effect, substitute $\log_{10}(X_d)$ for $X_d$.

The CONVERT_COORD function can be used to convert between coordinate systems. The user should save and restore these fields when switching between windows or devices with different sizes and/or scaling.

## STYLE

The style of the axis encoded as bits in a longword. The axis style can be set to exact, extended, none, or no box using this field. The following table lists the axis style bit values:

| Bit | Value | Function |
|---|---|---|
| 0 | 1 | Exact. By default, the end points of the axis are rounded in order to obtain even tick increments. Setting this bit inhibits rounding, making the axis fit the data range exactly. |
| 1 | 2 | Extend. If this bit is set, the axes are extended by 5% in each direction, leaving a border around the data. |
| 2 | 4 | None. If this bit is set, the axis and its annotation are not drawn. |
| 3 | 8 | No box. Normally, PLOT and CONTOUR draw a box-style axis with the data window surrounded by axes. |
| 4 | 16 | Inhibits setting the Y axis minimum value to zero when the data are all greater than 0. The keyword YNOZERO sets this bit temporarily. |

*Table D-8: Axis Style Bit Values*

Note that this system variable field is set bitwise, so multiple effects can be set by adding values together. For example, to make an X axis that is both exact (value 1) and suppresses the box style (setting 8), set the !X.STYLE system variable to `1+8`, or 9.

For example, to set the Y axis style to exact using the !Y system variable:

```
!Y.STYLE = 1
```

or by using a keyword parameter:

```
PLOT, X, Y, YSTYLE = 1
```

## THICK

The thickness of the axis line. 1.0 is normal.

## TICKFORMAT

Set this field to a format string or a string containing the name of a function that returns a string to be used to format the axis tick mark labels.

See “[XYZ]TICKFORMAT” on page 3883 for more information.

## TICKINTERVAL

A scalar indicating the interval between major tick marks for the first axis level. This setting takes precedence over ![XYZ].TICKS.

For example, if !X.TICKUNITS=[“Seconds”, “Hours”, “Days”], and !X.TICKINTERVAL=30, then the interval between major ticks for the first axis level will be 30 seconds.

See “[XYZ]TICKINTERVAL” on page 3885 for more information.

## TICKLAYOUT

Set this keyword to a scalar that indicates the tick layout style to be used to draw each level of the axis.

See “[XYZ]TICKLAYOUT” on page 3886 for more information.

## TICKLEN

The lengths of tick marks (expressed in normal coordinates) for the individual axes.

## TICKNAME

The annotation for each tick. A string array of up to 60 elements. Setting elements of this array allows direct specification of the tick label. If this element contains a null string, the default value, IDL annotates the thick with its numeric value. Setting the element to a 1-blank string suppresses the tick annotation.

For example, to produce a plot with an abscissa labeled with the days of the week:

```
;Set up X axis tick labels.
!X.TICKNAME = ['SUN', 'MON', 'TUE', 'WED', $
    'THU', 'FRI', 'SAT']

;Use six tick intervals, requiring seven tick labels.
!X.TICKS = 6

;Plot the data, this assumes that Y contains 7 elements.
PLOT, Y
```

The same plot can be produced, using keyword parameters, with:

```
;Set fields, as above, only temporarily.
PLOT, Y, XTICKN = ['SUN', 'MON', 'TUE', 'WED',$
    'THU', 'FRI', 'SAT'], XTICKS = 6
```

## TICKS

The number of major tick intervals to draw for the axis. If !X.TICKS is set to 0, the default, IDL will select from three to six tick intervals. Setting this field to *n*, where *n* > 1, produces exactly *n* tick intervals, and *n*+1 tick marks. Setting this field equal to 1 suppresses tick marks.

## TICKUNITS

Set this keyword to a string (or a vector of strings) indicating the units to be used for axis tick labeling.

**Note**

The singular form of each of the time value strings is also acceptable (e.g, !X.TICKUNITS='Day' is equivalent to !X.TICKUNITS='Days').

**Note**

To set the ![XYZ].TICKUNITS field to a single string, the following approach is recommended:

```
!X.TICKUNITS = ''     ; Clear all previous tick unit strings.
!X.TICKUNITS = ['Days']  ;Single unit string in array.
```

The following:

```
!X.TICKUNITS = 'Days'
```

will copy the 'Days' string to all levels, resulting in a multi-level axis.

See “[XYZ]TICKUNITS” on page 3887 for more information.

## TICKV

An array of up to 60 elements containing the data values for each tick mark. You can directly specify the location of each tick by setting !X.TICKS to the number of tick marks (the number of intervals plus 1) and storing the data values of the tick marks in !X.TICKV. If, as is true by default, !X.TICKV[0] is equal to !X.TICKV[1], IDL automatically determines the value of the tick marks.

## TITLE

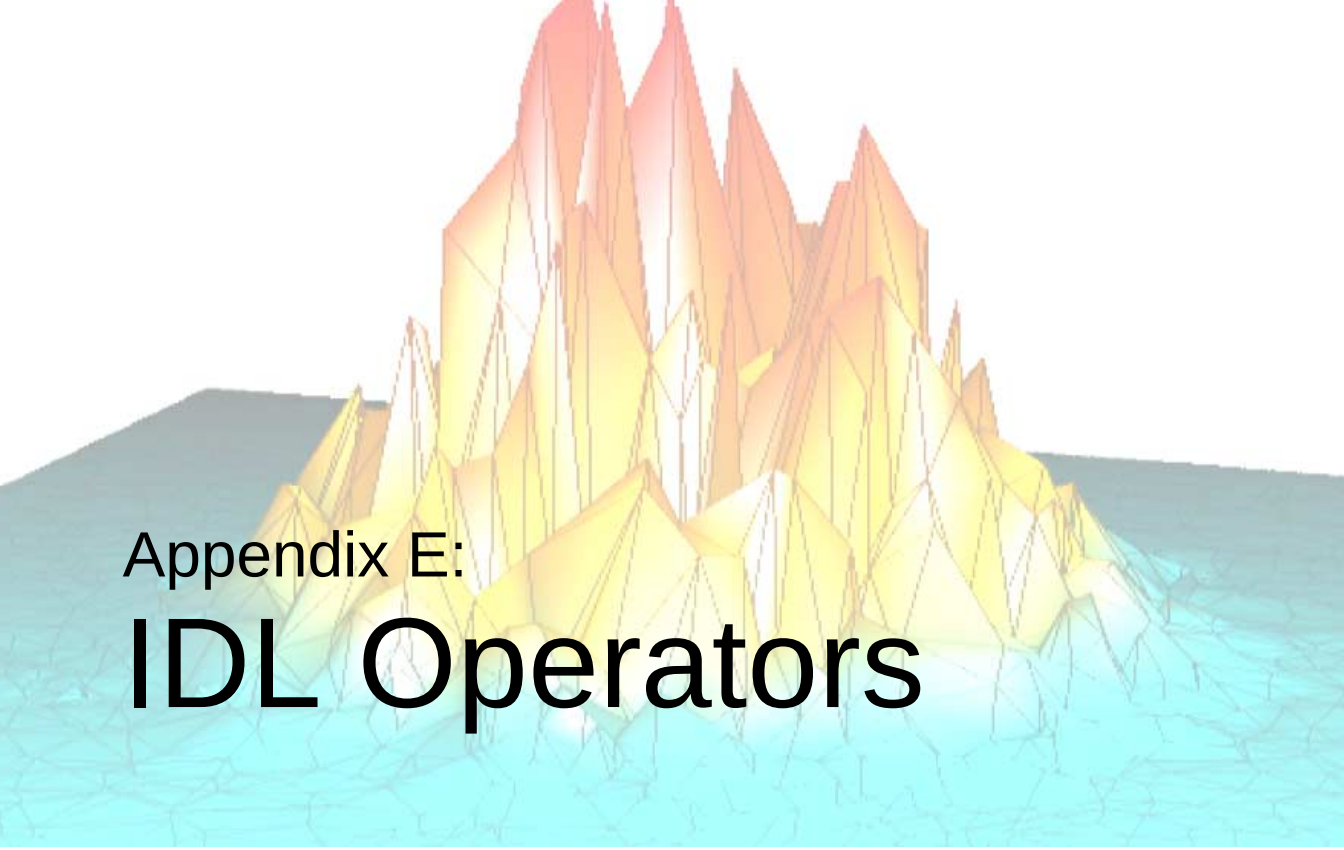
A string containing the axis title.

## TYPE

The type of axis, 0 for linear, 1 for logarithmic.

## WINDOW

Contains the normalized coordinates of the axis end points, the plot data window. This field is set by PLOT, CONTOUR, SHADE_SURF, and SURFACE. Changing its value has no effect. A 2-element floating point array. To change the default plotting window, set !P.POSITION. The keyword parameter POSITION sets the plot data window on a per call basis.



# Appendix E: IDL Operators

This appendix lists all IDL operators and provides brief examples of their usage. For more information on IDL operators, see Chapter 2, “Expressions and Operators” in the *Building IDL Applications* manual. The following topics are covered in this appendix:

# Mathematical Operators

| Operator | Description | Example |
|---|---|---|
| + | Addition | ;Store the sum of 3 and 6 in B:<br>B = 3 + 6 |
| | String Concatenation | ;Store the string value of "John Doe" in B:<br>B = 'John' + ' ' + 'Doe' |
| ++ | Increment | Adds one to the operand:<br>A = 3<br>A++<br>PRINT, A<br>IDL Prints:<br>4<br>**Note -** The increment operator supports both pre- and post-fix syntax. See "Increment/Decrement" in Chapter 2 of the *Building IDL Applications* manual. |
| – | Subtraction | ;Store the value of 5 subtracted from 9 in C:<br>C = 9 - 5 |
| | Negation | ;Change the sign of C:<br>C = -C |
| -- | Decrement | Subtracts one from the operand:<br>A = 3<br>A--<br>PRINT, A<br>IDL Prints:<br>2<br>**Note -** The decrement operator supports both pre- and post-fix syntax. See "Increment/Decrement" in Chapter 2 of the *Building IDL Applications* manual. |

*Table E-1: Mathematical Operators*

| Operator | Description | Example |
|---|---|---|
| * | Multiplication | `;Store the product of 2 and 5 in variable C:`<br>`C = 2 * 5` |
| | Pointer dereference | If `ptr` is a valid pointer (created via the PTR_NEW function), then `*ptr` is the value held by the heap variable that `ptr` points to. For more information on IDL pointers, see Chapter 8, "Pointers" in the *Building IDL Applications* manual. |
| / | Division | `;Store result of 10.0 divided by 3.2 in`<br>`;variable D:`<br>`D = 10.0/3.2` |
| ^ | Exponentiation | `;Store result of 2 raised to the 3rd power in`<br>`;variable B:`<br>`B = 2^3` |
| MOD | Modulo | `;Print the value of 9 modulo 5:`<br>`PRINT, 9 MOD 5`<br><br>IDL Prints:<br>`4` |

*Table E-1: Mathematical Operators (Continued)*

# Minimum and Maximum Operators

| Operator | Description | Example |
|---|---|---|
| < | Minimum operator. The value of "A < B" is equal to the smaller of A or B.<br>For complex numbers the absolute value is used. | ;Set A equal to 3.<br>A = 5 < 3<br><br>;Set all points in array ARR that are larger<br>;than 100 to 100:<br>ARR = ARR < 100<br><br>;Set X to the smallest of the three operands:<br>X = X0 < X1 < X2 |
| > | Maximum operator. "A > B" is equal to the larger of A or B.<br>For complex numbers the absolute value is used. | ;'>' is used to avoid taking the log of zero<br>;or negative numbers:<br>C = ALOG(D > 1E - 6)<br><br>;Plot positive points only. Negative points<br>;are plotted as zero:<br>PLOT, ARR > 0 |

*Table E-2: Minimum and Maximum Operators*

# Matrix Operators

| Operator | Description | Example |
|---|---|---|
| # | Computes array elements by multiplying the columns of the first array by the rows of the second array. | ;A 3-column by 2-row array:<br>array1 = [ [1, 2, 1], [2, -1, 2] ]<br>;A 2-column by 3-row array:<br>array2 = [ [1, 3], [0, 1], [1, 1] ]<br>PRINT, array1#array2<br><br>IDL prints:<br>7 -1 7<br>2 -1 2<br>3 1 3 |
| ## | Computes array elements by multiplying the rows of the first array by the columns of the second array. | ;A 3-column by 2-row array:<br>array1 = [ [1, 2, 1], [2, -1, 2] ]<br>;A 2-column by 3-row array:<br>array2 = [ [1, 3], [0, 1], [1, 1] ]<br>PRINT, array1##array2<br><br>IDL prints:<br>2 6<br>4 7 |

*Table E-3: Matrix Operators*

# Logical Operators

| Operator | Description | Example |
|---|---|---|
| && | Logical AND.<br>Returns 1 whenever both of its operands are true; otherwise, returns 0. Non-zero numerical values, non-null strings, and non-null heap variables (pointers and object references) are considered true, everything else is false.<br>Operands must be scalars or single-element arrays. The && operator *short-circuits*; the second operand will not be evaluated if the first is false. | `PRINT, 5 && 7`<br>IDL Prints: `1`<br><br>`PRINT, 5 && 2`<br>IDL Prints: `1`<br><br>`PRINT, 4 && 0`<br>IDL Prints: `0` |
| \|\| | Logical OR.<br>Returns 1 whenever either of its operands are true; otherwise, returns 0. Uses the same test for "truth" as the && operator.<br>Operands must be scalars or single-element arrays. The \|\| operator *short-circuits*; the second operand will not be evaluated if the first is true. | `IF ((5 GT 3) \|\| (4 GT 5)) THEN $`<br>`  PRINT, 'True'`<br><br>IDL Prints:<br>`True` |
| ~ | Logical negation.<br>Returns 1 when its operand is false; otherwise, returns 0.<br>Uses the same test for "truth" as the && operator. | `PRINT, ~ [1, 2, 0]`<br><br>IDL Prints:<br>`0  0  1` |

*Table E-4: Logical Operators*

# Bitwise Operators

| Operator | Description | Example |
|---|---|---|
| AND | Bitwise AND.<br>For integer, longword, and byte operands, a bitwise AND operation is performed. For operations on other types, the result is equal to the second operand if the first operand is not equal to zero or the null string; otherwise, the result is zero or the null string. | `PRINT, (5 GT 2) AND (4 GT 2)`<br>IDL Prints: `1`<br><br>`PRINT, (5 GT 2) AND (4 GT 5)`<br>IDL Prints: `0`<br><br>`PRINT, 5 AND 7`<br>IDL Prints: `5`<br><br>`PRINT, 5 AND 2`<br>IDL Prints: `0`<br><br>`PRINT, 4 AND 2`<br>IDL Prints: `0` |
| NOT | Bitwise complement.<br>For integer, longword, and byte operands, NOT returns the complement of each bit of the operand. For floating-point operands, the result is 1.0 if the operand is zero; otherwise, the result is zero. Not valid for string or complex operands. | `PRINT, NOT 1`<br><br>IDL Prints:<br>`-2`<br><br>`IF (NOT (5 GT 6)) THEN $`<br>`  PRINT, 'True'`<br><br>IDL Prints:<br>`True` |
| OR | Bitwise OR.<br>For integer or byte operands, a bitwise inclusive OR is performed. For floating- point operands, returns the first operand if it is non-zero, or the 2nd operand otherwise. | `IF ((5 GT 3) OR (4 GT 5)) THEN $`<br>`  PRINT, 'True'`<br><br>IDL Prints:<br>`True` |

*Table E-5: Logical Operators*

| Operator | Description | Example |
|---|---|---|
| XOR | Bitwise exclusive OR.<br>XOR is only valid for byte, integer, and longword operands. A bit in the result is set to 1 if the corresponding bits in the operands are different; if they are equal, it is set to zero. | `IF ((5 GT 3) XOR (4  GT 5)) THEN $`<br>`  PRINT, 'Different' $`<br>`  ELSE PRINT, 'Same'`<br><br>IDL Prints:<br>`Different` |

*Table E-5: Logical Operators (Continued)*

# Relational Operators

| Operator | Description | Example |
|---|---|---|
| EQ | Equal to | `;Determine if A equals B:`<br>`IF (A EQ B) THEN PRINT, 'True'` |
| GE | Greater than or equal to | `;Determine if A is greater than or equal`<br>`;to B:`<br>`IF (A GE B) THEN PRINT, 'True'` |
| GT | Greater than | `;Determine if A is greater than B:`<br>`IF (A GT B) THEN PRINT, 'True'` |
| LE | Less than or equal to | `;Determine if A is less than or equal`<br>`;to B:`<br>`IF (A LE B) THEN PRINT, 'True'` |
| LT | Less than | `; Determine if A is less than B:`<br>`IF (A LT B) THEN PRINT, 'True'` |
| NE | Not equal to | `; Determine if A does not equal B:`<br>`IF (A NE B) THEN PRINT, 'True'` |

*Table E-6: Relational Operators*

# Other Operators

| Operator | Description | Examples |
|---|---|---|
| [ ] | Array concatenation.<br>The expression `[A,B]` is an array formed by concatenating A and B. | `;Define C as three-point vector:`<br>`C = [0, 1, 3]`<br><br>`;Add 5 to the end of C:`<br>`PRINT, [C, 5]`<br>IDL Prints: `0 1 3 5`<br><br>`;Insert -1 at the beginning of C:`<br>`PRINT, [-1, C]`<br>IDL Prints: `-1 0 1 3` |
| | Enclose array subscripts | `A = [2, 1, 5]`<br>`;Print the 3rd element in A:`<br>`PRINT, A[2]`<br>IDL Prints: `5` |
| ( ) | Group expressions to control order of evaluation | `PRINT, 3 + 4 * 2 ^ 2 /2`<br>IDL Prints: `11`<br><br>`PRINT, (3 + (4 * 2) ^ 2 / 2)`<br>IDL Prints: `35` |
| = | Assignment | `;Assign 5 to variable A:`<br>`A = 5`<br><br>`;Assign "Hello World" to variable B:`<br>`B='Hello World'` |

*Table E-7: Other Operators*

| Operator | Description | Examples |
|---|---|---|
| *op*= | Compound Assignment where *op* is one of the following operators: ##, #, *, +, -, /, <, >, ^, AND, EQ, GE, GT, LE, LT, MOD, NE, OR, XOR | Applies the specified operation to the target variable "in place," without making a copy of the variable. For example,<br>`A += 5`<br>adds 5 to the value of the variable A.<br>**Note -**<br>`A op= expression`<br>is equivalent to:<br>`A = TEMPORARY(A) op (expression)`<br>See "Compound Assignment Operators" in Chapter 11 of the *Building IDL Applications* manual for details. |
| ?: | Conditional expression. For<br>*value=expr1 ? expr2 : expr3*<br>*expr1* is evaluated first. If *expr1* is true, then *value=expr2*. If *expr1* is false, *value=expr3*. | `A=6 & B=4`<br>`;Set Z to the greater of A and B:`<br>`Z = (A GT B) ? A : B`<br>`PRINT, Z`<br>IDL Prints: `6` |

*Table E-7: Other Operators (Continued)*

# Operator Precedence

The following table lists IDL's operator precedence. Operators with the highest precedence are evaluated first. Operators with equal precedence are evaluated from left to right.

| Priority | Operator |
|---|---|
| First (highest) | ( ) (parentheses, to group expressions) |
| | [ ] (brackets, to concatenate arrays) |
| Second | . (structure field dereference) |
| | [ ] (brackets, to subscript an array) |
| | ( ) (parentheses, used in a function call) |
| Third | * (pointer dereference) |
| | ^ (exponentiation) |
| | ++ (increment) |
| | -- (decrement) |
| Fourth | * (multiplication) |
| | # and ## (matrix multiplication) |
| | / (division) |
| | MOD (modulus) |
| Fifth | + (addition) |
| | - (subtraction and negation) |
| | < (minimum) |
| | > (maximum) |
| | NOT (bitwise negation) |

*Table E-8: Operator Precedence*

| Priority | Operator |
|---|---|
| Sixth | EQ (equality) |
| | NE (not equal) |
| | LE (less than or equal) |
| | LT (less than) |
| | GE (greater than or equal) |
| | GT (greater than) |
| Seventh | AND (bitwise AND) |
| | OR (bitwise OR) |
| | XOR (bitwise exclusive OR) |
| Eighth | && (logical AND) |
| | \|\| (logical OR) |
| | ~ (logical negation) |
| Ninth | ?: (conditional expression) |

*Table E-8: Operator Precedence (Continued)*

# Appendix F: Special Characters

Within the IDL environment, a number of characters have special meanings.

The following table lists characters with special interpretations and states their functions in IDL. These characters are discussed further in the descriptions following the table.

| Character | Function |
|---|---|
| ! | • First character of system variable names and font-positioning commands. |
| ' | • Delimit string constants<br>• Indicate part of octal or hex constant |
| ; | • Begin comment field |

*Table F-1: Special Characters*

| Character | Function |
|---|---|
| $ | • Continue current command on the next line<br>• Issue operating system command if entered on a line by itself. |
| " | • Delimit string constants or precede octal constants |
| . | • Indicate constant is floating point<br>• Start executive command |
| & | • Separate multiple statements on one line |
| : | • End label identifiers<br>• Separate start and end subscript ranges |
| * | • Multiplication operator<br>• Array subscript range<br>• Pointer dereference (if in front of a valid pointer) |
| @ | • Include file<br>• Execute IDL batch file |
| ? | • Invokes online help when entered at the IDL command line.<br>• Part of the ?: ternary operator used in conditional expressions. |

*Table F-1: Special Characters (Continued)*

# Exclamation Point (!)

The exclamation point is the first character of names of IDL system-defined variables. System variables are predefined scalar variables of a fixed type. Their purpose is to override defaults for system procedures, to return status information, and to control the action of IDL.

## Apostrophe (')

The apostrophe delimits string literals and indicates part of an octal or hex constant.

## Semicolon (;)

The semicolon is the first character of the optional comment field of an IDL statement. All text on a line following a semicolon is ignored by IDL. A line can consist of a comment only or both a valid statement and a comment.

## Dollar Sign ($)

The dollar sign at the end of a line indicates that the current statement is continued on the following line. The dollar sign character can appear anywhere a space is legal except within a string constant or between a function name and the first open parenthesis. Any number of continuation lines are allowed.

When the $ character is entered as the first character after the IDL prompt, the rest of the line is sent to the operating system as a command. If $ is the only character present, an interactive subprocess is started. Under UNIX, IDL execution suspends until the new shell process terminates.

## Quotation Mark (")

The quotation mark precedes octal numbers, which are always integers, and delimits string constants. Example: "`100B` is a byte constant equal to 64 base 10 and "`Don't drink the water`" is a string constant.

## Period (.)

The period or decimal point indicates in a numeric constant that the number is of floating-point or double-precision type. Example: 1.0 is a floating-point number. Also, in response to the IDL prompt, the period begins an executive command. For example,

```
.run myfile
```

causes IDL to compile the file *myfile.pro*. If *myfile.pro* contains a main program, the program also will be executed. In addition, the period precedes the name of a tag when referring to a field within a structure. For example, a reference to a tag called NAME in a structure stored in the variable A is A.NAME.

# Ampersand (&)

The ampersand separates multiple statements on one line. Statements can be combined until the maximum line length is reached. For example, the following line contains two statements:

```
I = 1 & PRINT, 'value:', I
```

# Colon (:)

The colon ends label identifiers. Labels can only be referenced by GOTO and ON_ERROR statements. The following line contains a statement with the label LOOP1.

```
LOOP1: X = 2.5
```

The colon also separates the starting and ending subscripts in subscript range specifiers. For example, A(3:6) designates elements three to six of the variable A.

# Asterisk (*)

The asterisk represents one of the following, depending on context:

1. Multiplication (3 * 3).
2. An ending subscript range equal to the size of the dimension. For example, `A[3:*]` represents all elements of the vector A from A[3] to the last element, while `B[*,3]` represents all elements of row four of matrix B.
3. A pointer dereference operation. For example, if `ptr` is a valid pointer (created via the PTR_NEW function), then `*ptr` is the value held by the heap variable that `ptr` points to. For more information on IDL pointers, see Chapter 8, "Pointers" in the *Building IDL Applications* manual.

# At Sign (@)

The "at" sign is used both as an include character and to signal batch execution.

## @ as an Include Character

The "at" sign at the beginning of a line causes the IDL compiler to substitute the contents of the file whose name appears after the @ for the line. If the full path name is not specified after the @ symbol, IDL searches the current directory and a list of known locations where procedures are kept.

- **UNIX:** IDL searches for the file in the list of directories (as established by the environment variable IDL_PATH) stored in the system variable !PATH.
- **Windows:** IDL searches for the file in the list of directories stored in the system variable !PATH (specified in the “Preferences” dialog of the File menu).

For example, the line

```
@doit
```

when included in a file, causes the file *doit.pro* to be compiled in its place. (The suffix *.pro* is the default for IDL program files.) When the end of the file is reached, compilation resumes at the line after the @.

### @ to Signal Batch Processing

When IDL is running in interactive mode, a line beginning with the character @ is entered in response to the IDL prompt and the file is opened for batch input. See Chapter 10, “Executing Batch Jobs in IDL” in the *Using IDL* manual for details.

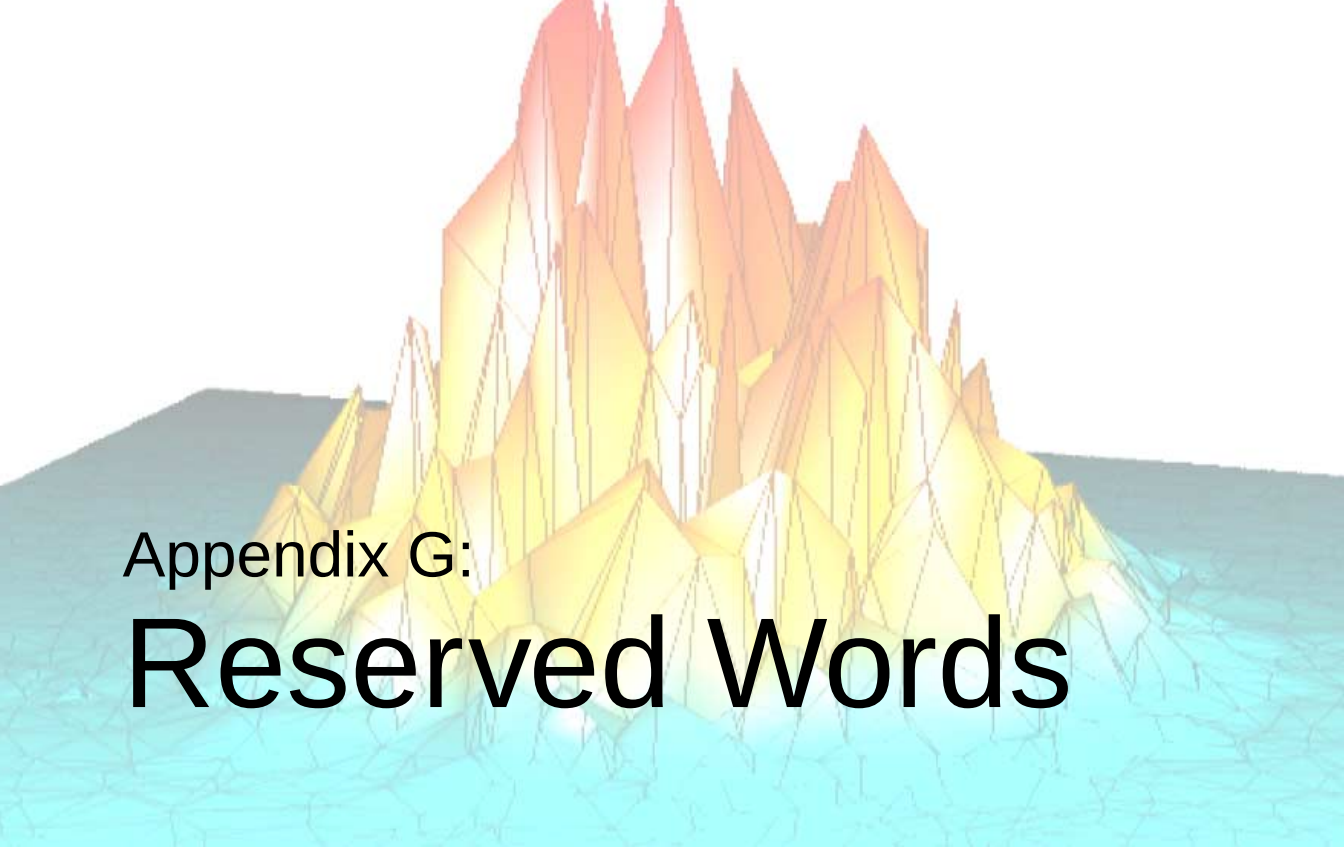
## Question Mark (?)

The question mark is used as follows:

- When entered at the IDL command line, the IDL online help facility is invoked.
- Used in conditional expressions as part of the ?: ternary operator. For example:

```
; A shorter way of saying IF (a GT b) THEN z=a ELSE z=b:
z = (a GT b) ? a : b
```

For more on conditional expressions, see “Conditional Expression” in Chapter 2 of the *Building IDL Applications* manual.

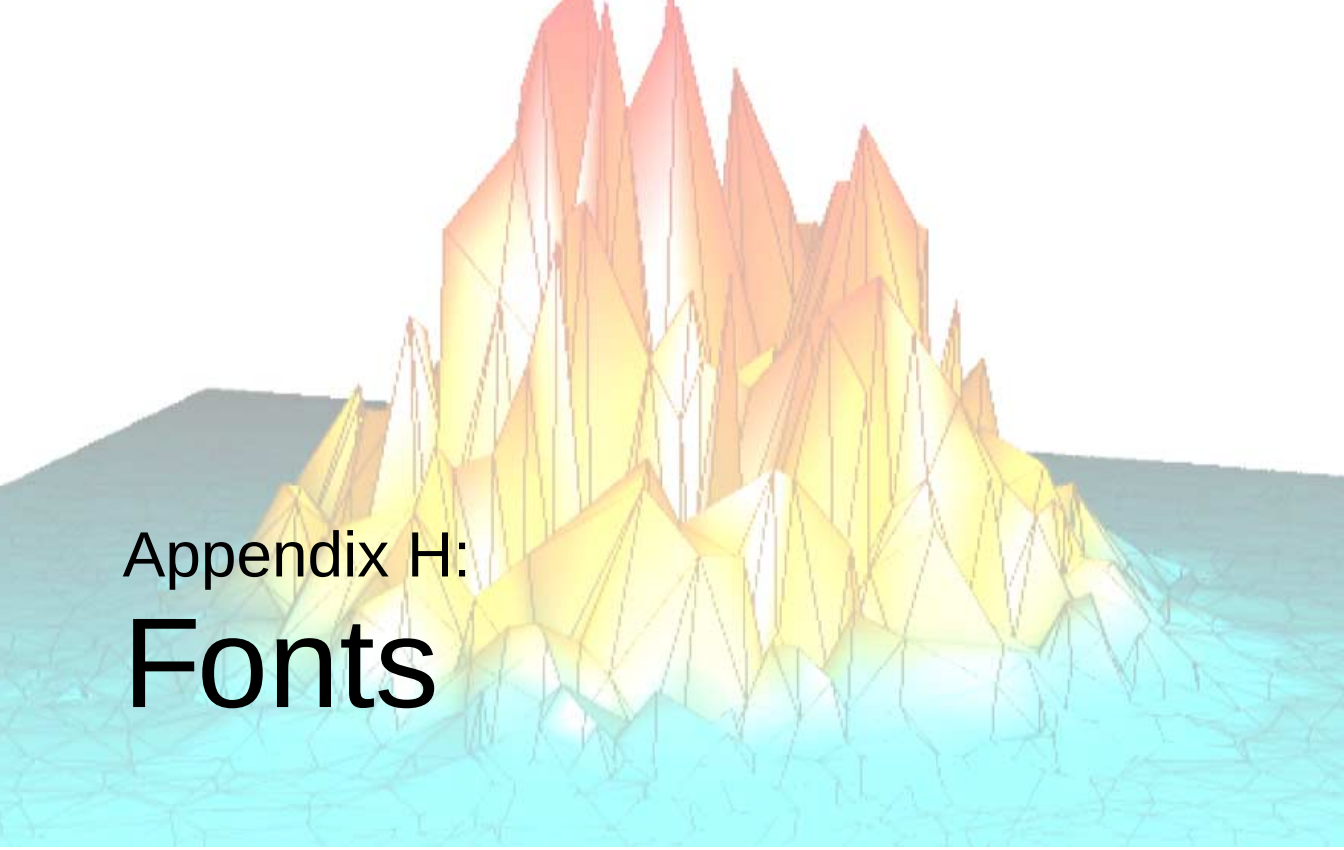


# Appendix G: Reserved Words

Variables, user-written procedures, and user-written functions should not have the same names as IDL functions or procedures. Re-using names of IDL routines can lead to syntax errors or to “hiding” variables. In addition, certain words representing IDL language constructs are strictly forbidden—using any of these *reserved words* as a variable, procedure, or function name will cause an immediate syntax error. The following table lists all of the reserved words in IDL.

| | | |
|---|---|---|
| AND | BEGIN | BREAK |
| CASE | COMMON | COMPILE_OPT |
| CONTINUE | DO | ELSE |
| END | ENDCASE | ENDELSE |
| ENDFOR | ENDIF | ENDREP |
| ENDSWITCH | ENDWHILE | EQ |
| FOR | FORWARD_FUNCTION | FUNCTION |

| | | |
|---|---|---|
| GE | GOTO | GT |
| IF | INHERITS | LE |
| LT | MOD | NE |
| NOT | OF | ON_IOERROR |
| OR | PRO | REPEAT |
| SWITCH | THEN | UNTIL |
| WHILE | XOR | |



# Appendix H: Fonts

The following topics are covered in this appendix:

# Overview

IDL uses three font systems for writing characters on the graphics device: Hershey (vector) fonts, TrueType (outline) fonts, and device (hardware) fonts. This chapter describes each of the three types of fonts, discusses when to use each type, and explains how to use fonts when creating graphical output in IDL.

Vector-drawn fonts, also referred to as *Hershey fonts*, are drawn as lines. They are device-independent (within the limits of device resolution). All vector fonts included with IDL are guaranteed to be available in any IDL installation. See "About Vector Fonts" on page 3954 for additional details.

TrueType fonts, also referred to here as *outline fonts*, are drawn as character outlines, which are filled when displayed. They are largely device-independent, but do have some device-dependent characteristics. Four TrueType font families are included with IDL; these fonts should display in a similar way on any IDL platform. TrueType font support for IDL Object Graphics was introduced in IDL version 5.0 and support in IDL Direct Graphics was introduced in IDL version 5.1. See "About TrueType Fonts" on page 3957 for additional details.

Device fonts, also referred to as *hardware fonts*, rely on character-display hardware or software built in to a specific display device. Device fonts, necessarily, are device-dependent and differ from platform to platform and display device to display device. See "About Device Fonts" on page 3962 for additional details.

# Fonts in IDL Direct vs. Object Graphics

This volume deals almost exclusively with IDL Direct Graphics. However, the vector and TrueType font systems described here are also available in the IDL Object Graphics system, described in *Using IDL*.

## IDL Direct Graphics

When generating characters for Direct Graphics plots, IDL uses the font system specified by the value of the system variable !P.FONT. The normal default for this variable is -1, which specifies that the built-in, vector-drawn (Hershey) fonts should be used. Setting !P.FONT equal to 1 specifies that TrueType fonts should be used. Setting !P.FONT equal to zero specifies that fonts supplied by the graphics device should be used.

The setting of the IDL system variable !P.FONT can be overridden for a single IDL Direct Graphics routine (AXIS, CONTOUR, PLOT, SHADE_SURF, SURFACE, or XYOUTS) by setting the FONT keyword equal to -1, 0, or 1.

Once a font system has been selected, an individual font can be chosen either via a formatting command embedded in a text string as described in “Embedded Formatting Commands” on page 3971, or by setting the value of the SET_FONT keyword to the DEVICE routine (see “SET_FONT” on page 3813).

## IDL Object Graphics

IDL Object Graphics can use the vector and TrueType font systems. See *Using IDL* for more information on using fonts with Object Graphics. Any TrueType fonts you add to your IDL installation as described in “About TrueType Fonts” on page 3957 will also be available to the Object Graphics system.

# About Vector Fonts

The vector fonts used by IDL were digitized by Dr. A.V. Hershey of the Naval Weapons Laboratory. Characters in the vector fonts are stored as equations, and can be scaled and rotated in three dimensions. They are drawn as lines on the current graphics device, and are displayed quickly and efficiently by IDL. The vector fonts are built into IDL itself, and are always available.

All the available fonts are illustrated in "Vector Font Samples" on page 3983. The default vector font (Font 3, Simplex Roman) is in effect if no font changes have been made.

## Using Vector Fonts

To use the vector font system with IDL Direct Graphics, either set the value of the IDL system variable !P.FONT equal to -1 (negative one), or set the FONT keyword of one of the Direct Graphics routines equal to -1. The vector font system is the default font system for IDL.

Once the vector font system is selected, use an embedded formatting command to select a vector font (or fonts) for each string. (See "Embedded Formatting Commands" on page 3971 for details on embedded formatting commands.) The font selected "sticks" from string to string; that is, if you change fonts in one string, future strings will use the new font until you change it again or exit IDL.

For example, to use the Duplex Roman vector font for the title of a plot, you would use a command that looks like this:

```
PLOT, mydata, TITLE="!5Title of my plot"
```

Consult *Using IDL* for details on using the vector font system with IDL Object Graphics.

## Specifying Font Size

To specify the size of a vector font, use the SET_CHARACTER_SIZE keyword to the DEVICE procedure. The SET_CHARACTER_SIZE keyword takes a two-

element vector as its argument. The first element specifies the width of the “average” character in the font (in pixels) and calculates a scaling factor that determines the height of the characters. (It is not important what the “average” character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The second element of the vector specifies the number of pixels between baselines of lines of text.

The ratio of the “average” character’s height to its width differs from font to font, so specifying the same value [*x*, *y*] to the SET_CHARACTER_SIZE keyword may produce characters of different sizes in different fonts.

**Note**

While the first element of the vector specified to SET_CHARACTER_SIZE is technically a width, it is important to note that the width value has no effect on the widths of individual characters in the font. The width value is used only to calculate the appropriate scaling factor for the font.

For example, the following IDL commands display the word “Hello There” on the screen, in letters based on an “average” character that is 70 pixels wide, with 90 pixels between lines:

```
DEVICE, SET_CHARACTER_SIZE=[70,90]
XYOUTS, 0.1, 0.5, 'Hello!CThere'
```

You can also use the CHARSIZE keyword to the graphics routines or the CHARSIZE field of the !P System Variable to change the size of characters to a multiple of the size of the currently-selected character size. For example, to create characters one half the size of the current character size, you could use the following command:

```
XYOUTS, 0.1, 0.5, 'Hello!CThere', CHARSIZE=0.5
```

**Note**

Changing CHARSIZE adjusts both the character size and the space between lines.

## ISO Latin 1 Encoding

The default font (Font 3, Simplex Roman) follows the ISO Latin 1 Encoding scheme and contains many international characters. The illustration of this font under “Vector Font Samples” on page 3983 can be used to find the octal codes for the special characters.

For example, suppose you want to display some text with an Angstrom symbol in it. Looking at the chart of font 3, we see that the Angstrom symbol has octal code 305. Non-printable characters can be represented in IDL using octal or hexadecimal

notation and the STRING function (see "Representing Non-Printable Characters" in Chapter 3 of the *Building IDL Applications* manual for details). So the Angstrom can be printed by inserting a `STRING("305B)` character in our text string as follows:

```
XYOUTS,.1, .5, 'Here is an Angstrom symbol: ' + STRING("305B), $
    /NORM, CHARSIZE=3
```

## Customizing the Vector Fonts

The EFONT procedure is a widget application that allows you to edit the Hershey fonts and save the results. Use this routine to add special characters or completely new, custom fonts to the Hershey fonts.

# About TrueType Fonts

A TrueType Font

Beginning with version 5.2, five TrueType font families are included with IDL. The fonts included are:

| Font Family | Italic | Bold | BoldItalic |
|---|---|---|---|
| Courier | Courier Italic | Courier Bold | Courier Bold Italic |
| Helvetica | Helvetica Italic | Helvetica Bold | Helvetica Bold Italic |
| Monospace Symbol | | | |
| Times | Times Italic | Times Bold | Times Bold Italic |
| Symbol | | | |

*Table H-1: TrueType Font Names*

When TrueType fonts are rendered on an IDL graphics device or destination object, the font outlines are first scaled to the proper size. After scaling, IDL converts the character outline information to a set of polygons using a triangulation algorithm. When text in a TrueType font is displayed, IDL is actually drawing a set of polygons calculated from the font information. This process has two side effects:

1. Computation time is used to triangulate and create the polygons. This means that you may notice a slight delay the first time you use text in a particular font and size. Once the polygons have been created, the information is cached by IDL and there is no need to re-triangulate each time text is displayed. Subsequent uses of the same font and size happen quickly.
2. Because the TrueType font outlines are converted into polygons, you may notice some chunkiness in the displayed characters, especially at small point sizes. The smoothness of the characters will vary with the quality of the TrueType font you are using, the point size, and the general smoothness of the font outlines.

# Using TrueType Fonts

To use the TrueType font system with IDL Direct Graphics, either set the value of the IDL system variable !P.FONT equal to 1 (one), or set the FONT keyword to on one of the Direct Graphics routines equal to 1.

Once the TrueType font system is selected, use the SET_FONT keyword to the DEVICE routine to select the font to use. The value of the SET_FONT keyword is a *font name string*. The font name is the name by which IDL knows the font; the names of the TrueType fonts included with IDL are listed under "About TrueType Fonts" on page 3957. Finally, specify the TT_FONT keyword in the call to the DEVICE procedure. For example, to use Helvetica Bold Italic, use the following statement:

```
DEVICE, SET_FONT='Helvetica Bold Italic', /TT_FONT
```

To use Times Roman Regular:

```
DEVICE, SET_FONT='Times', /TT_FONT
```

IDL's default TrueType font is 12 point Helvetica regular.

# Specifying Font Size

To specify the size of a TrueType font, use the SET_CHARACTER_SIZE keyword to the DEVICE procedure. The SET_CHARACTER_SIZE keyword takes a two-element vector as its argument. The first element specifies the width of the "average" character in the font (in pixels) and calculates a scaling factor that determines the height of the characters. (It is not important what the "average" character is; it is used only to calculate a scaling factor that will be applied to all of the characters in the font.) The second element of the vector specifies the number of pixels between baselines of lines of text.

The ratio of the "average" character's height to its width differs from font to font, so specifying the same value [*x*, *y*] to the SET_CHARACTER_SIZE keyword may produce characters of different sizes in different fonts.

**Note**

While the first element of the vector specified to SET_CHARACTER_SIZE is technically a width, it is important to note that the width value has no effect on the widths of individual characters in the font. The width value is used only to calculate the appropriate scaling factor for the font.

For example, the following IDL commands display the word "Hello There" on the screen in Helvetica Bold, in letters based on an "average" character that is 70 pixels wide, with 90 pixels between lines:

```
DEVICE, FONT='Helvetica Bold', /TT_FONT,
SET_CHARACTER_SIZE=[70,90]
XYOUTS, 0.1, 0.5, 'Hello!CThere'
```

You can also use the CHARSIZE keyword to the graphics routines or the CHARSIZE field of the !P System Variable to change the size of characters to a multiple of the size of the currently-selected character size. For example, to create characters one half the size of the current character size, you could use the following command:

```
XYOUTS, 0.1, 0.5, 'Hello!CThere', CHARSIZE=0.5
```

Note that changing the CHARSIZE adjusts both the character size and the space between lines.

## Using Embedded Formatting Commands

Embedded formatting commands allow you to position text and change fonts within a single line of text. A subset of the embedded formatting commands available for use with the vector fonts are also available when using the TrueType font system. See "Embedded Formatting Commands" on page 3971 for a list of in-line formatting commands.

## IDL TrueType Font Resource Files

The TrueType font system relies on a resource file named `ttfont.map`, located in the `resource/fonts/tt` subdirectory of the IDL directory. The format of the ttfont.map file is:

*`FontName FileName DirectGraphicsScale ObjectGraphicsScale`*

where the fields in each column must be separated by white space (spaces and/or tabs). The fields contain the following information

The *Fontname* field contains the name that would be used for the SET_FONT keywords to the DEVICE routine.

The *Filename* field contains the name of the TrueType font file. On UNIX platforms, IDL will search for the file specified in the *FileName* field in the current directory (that is, in the `resource/fonts/tt` subdirectory of the IDL directory) if a bare filename is provided, or it will look for the file in the location specified by the fully-qualified file name if a complete path is provided. Because different platforms use different path-specification syntax, we recommend that you place any TrueType font files you wish to add to the `ttfont.map` file in the `resource/fonts/tt` subdirectory of the IDL directory. On Windows platforms, this entry may be '*', in which case the font will be loaded from the operating system font list, but that the following two scale entries will be honored.

The *DirectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Direct Graphics device. If you want the tallest character in the font to fit exactly within the vertical dimension of the device's current character size (as set via the SET_CHARACTER_SIZE keyword to the DEVICE procedure), set the scale factor equal to 1.0. Change the scale factor to a smaller number to scale a smaller portion of the tallest character into the character size.

For example, suppose the tallest character in your font is "Ã". Setting the scale factor to 1.0 will scale this character to fit the current character size, and then apply the same scaling to all characters in the font. As a result, the letter "M" will fill only approximately 85% of the full height of the character size. To scale the font such that the height of the "M" fills the vertical dimension of the character size, you would include the value 0.85 in the scale field of the `ttfont.map` file.

The *ObjectGraphicsScale* field contains a correction factor that will be applied when choosing a scale factor for the glyphs prior to being rendered on a Object Graphics device. (This field works just like the *DirectGraphicsScale* field.) This scale factor should be set to 1.0 if the maximum ascent among all glyphs within a given font is to fit exactly within the font size (as set via the SIZE property to the IDLgrFont object).

## Adding Your Own Fonts

To add a your own font to the list of fonts known to IDL, use a text editor to edit the `ttfont.map` file, adding the *FontName*, *FileName*, *DirectGraphicsScale*, and *ObjectGraphicsScale* fields for your font. You will need to restart IDL for the changes to the `ttfont.map` file to take effect. On Windows systems, you can use fonts that are not mentioned in the `ttfont.map` file, as long as they are installed in the Fonts control panel, as described below.

**Warning**

If you choose to modify the `ttfont.map` file, be sure to keep a backup copy of the original file so you can restore the defaults if necessary. Note also that applications that use text may appear different on different platforms if the scale entries in the `ttfont.map` file have been altered.

## Where IDL Searches for Fonts

The TrueType font files included with IDL are located in the `resource/fonts/tt` subdirectory of the IDL directory. When attempting to resolve a font name (specified via the FONT keyword to the DEVICE procedure), IDL will look in the

`ttfont.map` file first. If it fails to find the specified font file in the `ttfont.map` file, it will search for the font file in the following locations:

## UNIX

No further search will be performed. If the specified font is not included in the `ttfont.map` file, IDL will substitute Helvetica.

## Microsoft Windows

If the specified font is not included in the `ttfont.map` file, IDL will search the list of fonts installed in the system (the fonts installed in the Font control panel). If the specified font is not found, IDL will substitute Helvetica.

# About Device Fonts

Device, or hardware, fonts are fonts that are provided directly by your system's hardware or by software other than IDL. In past releases of IDL, we have used the term "*hardware fonts*" extensively to discuss these types of fonts. This is because in the early days of IDL, computer displays were either text-only terminals or dedicated graphics display devices such as plotters or Tektronix graphics terminals. These graphics displays generally came with a set of fonts built-in; when IDL asked the device to display characters in a built-in font, it was making a request to the hardware to display those characters.

As computer displays have become more sophisticated, the concept of fonts provided "by the hardware" has expanded to include fonts provided by the computer's operating system, or by font-management software. For example, many computers now use font management software like Adobe Type Manager to manage the fonts made available by the operating system to all applications. We use the term "device font" to refer to a font that is available to one of IDL's graphics devices from a source *other than IDL itself*. (In this case, a "graphics device" can be either a Direct Graphics device as specified by the DEVICE routine or an Object Graphics "destination" such as a window or a printer.) While device fonts may include fonts only available because a particular piece of hardware knows how to draw characters in that font (a pen plotter is an example of a device that may still have its own special fonts), in most cases device fonts are fonts supplied by the operating system to any application that may want to use them.

## Which Device Fonts Are Available?

To determine which device fonts are available on your system and the exact font strings to specify for each, use the GET_FONTNAMES keyword to the DEVICE procedure. You can also use an operating system specific method to determine which fonts are available:

### UNIX

On most systems, the `xlsfonts` utility displays a list of fonts available to the operating system.

### Microsoft Windows

Fonts available to the system are displayed in the Fonts control panel. You may also have other fonts available if you use font-management software such as Adobe Type Manager.

## Using Device Fonts

To use the Device font system with IDL Direct Graphics, either set the value of the IDL system variable !P.FONT equal to 0 (zero), or set the FONT keyword to on one of the Direct Graphics routines equal to 0.

Once the Device font system is selected, use the SET_FONT keyword to the DEVICE routine to select the font to use. Because device fonts are specified differently on different platforms, the syntax of the *fontname* string depends on which platform you are using.

### UNIX

Usually, the window system provides a directory of font files that can be used by all applications. List the contents of that directory to find the fonts available on your system. The size of the font selected also affects the size of vector drawn text. On some machines, fonts are kept in subdirectories of `/usr/lib/X11/fonts`. You can use the `xlsfonts` command to list available X Windows fonts.

For example, to select the font 8X13:

```
!P.FONT = 0
DEVICE, SET_FONT = '8X13'
```

### Microsoft Windows

The SET_FONT keyword should be set to a string with the following form:

```
DEVICE, SET_FONT="font*modifier1*modifier2*...modifiern"
```

where the asterisk (*) acts as a delimiter between the font's name (*font*) and any modifiers. The string is *not* case sensitive. Modifiers are simply "keywords" that change aspects of the selected font. Valid modifiers are:

- For font weight: THIN, LIGHT, BOLD, HEAVY
- For font quality: DRAFT, PROOF
- For font pitch: FIXED, VARIABLE
- For font angle: ITALIC
- For strikeout text: STRIKEOUT
- For underlined text: UNDERLINE
- For font size: Any number is interpreted as the font height in pixels.

For example, if you have Garamond installed as one of your Windows fonts, you could select 24-pixel cell height Garamond italic as the font to use in plotting. The following commands tell IDL to use hardware fonts, change the font, and then make a simple plot:

```
!P.FONT = 0
DEVICE, SET_FONT = "GARAMOND*ITALIC*24"
PLOT, FINDGEN(10), TITLE = "IDL Plot"
```

This feature is compatible with TrueType and Adobe Type Manager (and, possibly, other type scaling programs for Windows). If you have TrueType or ATM installed, the TrueType or PostScript outline fonts are used so that text looks good at any size.

## Fonts and the PostScript Device

A special set of device fonts are available when the current Direct Graphics device is PS (PostScript). IDL includes font metric information for 35 standard PostScript fonts, and can create PostScript language files that include text in these fonts. (The 35 fonts known to IDL are listed in the following table; they the standard fonts included in memory in the vast majority of modern PostScript printers.) The PostScript font

metric files (`*.afm` files) are located in the `resource/fonts/ps` subdirectory of the IDL directory.

| | |
|---|---|
| AvantGarde-Book | Helvetica-Narrow-Oblique |
| AvantGarde-BookOblique | Helvetica-Oblique |
| AvantGarde-Demi | NewCenturySchlbk-Bold |
| AvantGarde-DemiOblique | NewCenturySchlbk-BoldItalic |
| Bookman-Demi | NewCenturySchlbk-Italic |
| Bookman-DemiItalic | NewCenturySchlbk-Roman |
| Bookman-Light | Palatino-Bold |
| Bookman-LightItalic | Palatino-BoldItalic |
| Courier | Palatino-Italic |
| Courier-Bold | Palatino-Roman |
| Courier-BoldOblique | Symbol |
| Courier-Oblique | Times-Bold |
| Helvetica | Times-BoldItalic |
| Helvetica-Bold | Times-Italic |
| Helvetica-BoldOblique | Times-Roman |
| Helvetica-Narrow | ZapfChancery-MediumItalic |
| Helvetica-Narrow-Bold | ZapfDingats |
| Helvetica-Narrow-BoldOblique | |

*Table H-2: Names of Supported PostScript Fonts*

## Using PostScript Fonts

To use a PostScript font in your Direct Graphics output, you must first specify that IDL use the device font system, they switch to the `PS` device, then choose a font using the SET_FONT keyword to the DEVICE procedure.

The following IDL commands choose the correct font system, set the graphics device, select the font Palatino Roman, open a PostScript file to print to, plot a simple data set, and close the PostScript file:

```
!P.FONT = 0
SET_PLOT, 'PS'
DEVICE, SET_FONT = 'Palatino-Roman', FILE = 'testfile.ps'
PLOT, INDGEN(10), TITLE = 'My Palatino Title'
DEVICE, /CLOSE
```

**Note**

Subsequent PostScript output will continue to use the font Palatino Roman until you explicitly change the font again, or exit IDL.

You can also specify PostScript fonts using a set of keywords to the DEVICE procedure. The keyword combinations for the fonts included with IDL are listed in the following table.

| PostScript Font | DEVICE Keywords |
|---|---|
| Courier | /COURIER |
| Courier Bold | /COURIER, /BOLD |
| Courier Oblique | /COURIER, /OBLIQUE |
| Courier Bold Oblique | /COURIER, /BOLD, /OBLIQUE |
| Helvetica | /HELVETICA |
| Helvetica Bold | /HELVETICA, /BOLD |
| Helvetica Oblique | /HELVETICA, /OBLIQUE |
| Helvetica Bold Oblique | /HELVETICA, /BOLD, /OBLIQUE |
| Helvetica Narrow | /HELVETICA, /NARROW |
| Helvetica Narrow Bold | /HELVETICA, /NARROW, /BOLD |
| Helvetica Narrow Oblique | /HELVETICA, /NARROW, /OBLIQUE |
| Helvetica Narrow Bold Oblique | /HELVETICA, /NARROW, /BOLD, /OBLIQUE |
| ITC Avant Garde Gothic Book | /AVANTGARDE, /BOOK |
| ITC Avant Garde Gothic Book Oblique | /AVANTGARDE, /BOOK, /OBLIQUE |
| ITC Avant Garde Gothic Demi | /AVANTGARDE, /DEMI |

*Table H-3: The Standard 35 PostScript Fonts*

| PostScript Font | DEVICE Keywords |
|---|---|
| ITC Avant Garde Gothic Demi Oblique | /AVANTGARDE, /DEMI, /OBLIQUE |
| ITC Bookman Demi | /BKMAN, /DEMI |
| ITC Bookman Demi Italic | /BKMAN, /DEMI, /ITALIC |
| ITC Bookman Light | /BKMAN, /LIGHT |
| ITC Bookman Light Italic | /BKMAN, /LIGHT, /ITALIC |
| ITC Zapf Chancery Medium Italic | /ZAPFCHANCERY, /MEDIUM, /ITALIC |
| ITC Zapf Dingbats | /ZAPFDINGBATS |
| New Century Schoolbook | /SCHOOLBOOK |
| New Century Schoolbook Bold | /SCHOOLBOOK, /BOLD |
| New Century Schoolbook Italic | /SCHOOLBOOK, /ITALIC |
| New Century Schoolbook Bold Italic | /SCHOOLBOOK, /BOLD, /ITALIC |
| Palatino | /PALATINO |
| Palatino Bold | /PALATINO, /BOLD |
| Palatino Italic | /PALATINO, /ITALIC |
| Palatino Bold Italic | /PALATINO, /BOLD, /ITALIC |
| Symbol | /SYMBOL |
| Times | /TIMES |
| Times Bold | /TIMES, /BOLD |
| Times Italic | /TIMES, /ITALIC |
| Times Bold Italic | /TIMES, /ITALIC, /BOLD |

*Table H-3: The Standard 35 PostScript Fonts (Continued)*

For example to use the PostScript font Palatino Bold Italic, you could use either of the following DEVICE commands:

```
DEVICE, SET_FONT = 'Palatino*Bold*Italic'
DEVICE, /PALATINO, /BOLD, /ITALIC
```

## Changing the PostScript Font Assigned to an Index

You can change the PostScript font assigned to a given font index using the FONT_INDEX keyword to the DEVICE procedure. Font indices and their use are discussed in "Embedded Formatting Commands" on page 3971.

Changing the font index assigned to a font can be useful when changing PostScript fonts in the middle of a text string. For example, the following statements map Palatino Bold Italic to font index 4, and then output text using that font and the Symbol font:

```
; Map the font selected by !4 to be PalatinoBoldItalic:
DEVICE, /PALATINO, /BOLD, /ITALIC, FONT_INDEX=4
; Output "Alpha :" in PalatinoBoldItalic followed by an
; Alpha character:
XYOUTS, .3, .5, /NORMAL, "!4Alpha: !9a", FONT=0, SIZE=5.0
```

## Adding Your Own PostScript Fonts

Because the 35 PostScript fonts included with IDL are built in to a PostScript printer's memory, the IDL distribution includes only the font metric files, which provide positioning information. In addition, the `.afm` files used by IDL are specially processed to provide the information in a format IDL expects.

You can add your own PostScript fonts to the list of fonts known to IDL if you have access to the PostScript font file (usually named *font*`.pfb`) to load into your printer and to the *font*`.afm` file supplied by Adobe. You can convert the standard `.afm` file into a file IDL understands using the IDL routine PSAFM. Consult the file `README.TXT` in the `resource/fonts/ps` subdirectory of the IDL directory for details on adding PostScript fonts to your system.

# Choosing a Font Type

Some of the issues involved in choosing between vector, TrueType, and device fonts are explained below.

## Appearance

Vector-drawn characters are of medium quality, suitable for most uses. TrueType characters are of relatively high quality, although at some point sizes the triangulation process (described in "About TrueType Fonts" on page 3957) may cause characters to appear slightly jagged. The appearance of device characters varies from mediocre (characters found in many graphics terminals) to publication quality (PostScript).

## Three-Dimensional Transformations

Vector or TrueType fonts should always be used with three-dimensional transformations. Both vector and TrueType characters pass through the same transformations as the rest of the plot, yielding a better looking plot. See "Three-Dimensional Graphics" in Chapter 18 of the *Using IDL* manual for an example of vector-drawn characters with three-dimensional graphics. Device characters are not subject to the three-dimensional transforms.

## Portability

The vector-drawn fonts work using any graphics device and look the same on every device (within the limitations of device resolution) on any system supported by IDL.

TrueType fonts are available only on the `X`, `WIN`, `PRINTER`, `PS`, and `Z` Direct Graphics devices, and in IDL's Object Graphics system. If you use only the fonts supplied with IDL, TrueType fonts also look the same on every supported device (again within the limits of the device resolution). If you use TrueType fonts other than those supplied with IDL, your font may not be installed on the system which runs your program. In this case, IDL will substitute a known font for the missing font.

The appearance, size, and availability of device fonts varies greatly from device to device. Many, if not most, of the positioning and font changing commands recognized by the vector-drawing routines are ignored when using device fonts. The exception to this rule is the Direct Graphics `PS` device; if you use one of the PostScript fonts supported by IDL, the PostScript output from the `PS` device will be identical between platforms.

## Computational Time

Device fonts are generally rendered the most quickly, since the hardware device or operating system handles all computations and caching.

It takes more computer time to draw characters with line vectors and generally results in more input/output. However, this is not an important issue unless the plot contains a large number of characters or the transmission link to the device is very slow.

The initial triangulation step used when displaying TrueType fonts for the first time can be computationally expensive. However, since the font shapes are cached, subsequent uses of the same font are relatively speedy.

## Flexibility

Vector-drawn fonts provide a great deal of flexibility. There are many different typefaces available, as shown in the tables at the end of this chapter. In addition, such fonts can be arbitrarily scaled, rotated, and transformed.

TrueType fonts support fewer embedded formatting commands than do the vector fonts, and cannot be scaled, rotated, or transformed.

The abilities of hardware-generated characters differ greatly between devices so it is not possible to make a blanket statement on when they should be used—the best font to use depends on the available hardware. In general, however, the vector or TrueType fonts are easier to use and often provide superior results to what is available from the hardware. See the discussion of the device you are using in Appendix A, “IDL Graphics Devices” for details on the hardware-generated characters provided by that device.

## Print Quality

For producing publication-quality output, we recommend using either the TrueType font system or the Direct Graphics PS device and one of the PostScript fonts supported by IDL.

# Embedded Formatting Commands

When you use vector, TrueType, and some device fonts, text strings can include embedded formatting commands that facilitate subscripting, superscripting, and equation formatting. The method used is similar to that developed by Grandle and Nystrom (1980). Embedded formatting commands are always introduced by the exclamation mark, ( ! ). (The string " ! ! " is used to produce a literal exclamation mark.)

**Note**

Embedded formatting commands prefaced by the exclamation mark have no special significance for hardware-generated characters unless the ability is provided by the particular device in use. The IDL PostScript device driver accepts many of the standard embedded formatting commands, and is described here. If you wish to use hardware fonts with IDL Direct Graphics devices other than the PostScript device, consult the description of the device in Appendix A, "IDL Graphics Devices" before trying to use these commands with hardware characters.

You can determine whether embedded formatting commands are available for use with device fonts on your current graphics device by inspecting bit 12 of the *Flags* field of the !D System Variable. Use the IDL statement:

```
IF (!D.FLAGS AND 4096) NE 0 THEN PRINT, 'Bit is set.'
```

to determine whether bit 12 of the *Flags* field is set for the current graphics device.

## Changing Fonts within a String

You can change fonts one or more times within a text string using the embedded font commands shown in the table below. The character following the exclamation mark can be either upper or lower case.

Examples of commands used to change fonts in mid-string are included in "Formatting Command Examples" on page 3975.

| Command | Vector Font | TrueType Font | PostScript Font |
|---|---|---|---|
| !3 | Simplex Roman (default) | Helvetica | Helvetica |
| !4 | Simplex Greek | Helvetica Bold | Helvetica Bold |
| !5 | Duplex Roman | Helvetica Italic | Helvetica Narrow |

*Table H-4: Embedded Font Selection Commands*

| Command | Vector Font | TrueType Font | PostScript Font |
|---|---|---|---|
| !6 | Complex Roman | Helvetica Bold Italic | Helvetica Narrow Bold Oblique |
| !7 | Complex Greek | Times | Times Roman |
| !8 | Complex Italic | Times Italic | Times Bold Italic |
| !9 | Math/special characters | Symbol | Symbol |
| !M | Math/special characters (change effective for one character only) | Symbol | Symbol |
| !10 | Special characters | Symbol * | Zapf Dingbats |
| !11(!G) | Gothic English | Courier | Courier |
| !12(!W) | Simplex Script | Courier Italic | Courier Oblique |
| !13 | Complex Script | Courier Bold | Palatino |
| !14 | Gothic Italian | Courier Bold Italic | Palatino Italic |
| !15 | Gothic German | Times Bold | Palatino Bold |
| !16 | Cyrillic | Times Bold Italic | Palatino Bold Italic |
| !17 | Triplex Roman | Helvetica * | Avant Garde Book |
| !18 | Triplex Italic | Helvetica * | New Century Schoolbook |
| !19 | | Helvetica * | New Century Schoolbook Bold |
| !20 | Miscellaneous | Helvetica * | Undefined User Font |
| !X | Revert to the entry font | Revert to the entry font | Revert to the entry font |

* The font assigned to this index may be replaced in a future release of IDL.

*Table H-4: Embedded Font Selection Commands (Continued)*

# Positioning Commands

The positioning and other font-manipulation commands are described in the following table. Examples of commands used to position text are included in “Formatting Command Examples” on page 3975.

| Command | Action |
|---|---|
| !A | Shift above the division line . |
| !B | Shift below the division line . |
| !C | “Carriage return,” begins a new line of text. Shift back to the starting position and down one line. This command also performs an implicit “!N” command, returning to the normal level and character size at the beginning of the new line. |
| !D | Shift down to the first level subscript and decrease the character size by a factor of 0.70. |
| !E | Shift up to the exponent level and decrease the character size by a factor of 0.44. |
| !I | Shift down to the index level and decrease the character size by a factor of 0.44. |
| !L | Shift down to the second level subscript. Decrease the character size by a factor of 0.62. |
| !N | Shift back to the normal level and original character size. |
| !R | Restore position. The current position is set from the top of the saved positions stack. |
| !S | Save position. The current position is saved on the top of the saved positions stack. |
| !U | Shift to upper subscript level. Decrease the character size by a factor of 0.70. |
| !X | Return to the entry font. |

*Table H-5: Vector-Drawn Positioning and Miscellaneous Commands*

| Command | Action |
|---|---|
| !Z($u_0$,$u_1$,...,$u_n$) | Display one or more character glyphs according to their unicode value. Each $u_i$ within the parentheses will be interpreted as a 16-bit hexadecimal unicode value. If more than one unicode value is to be included, the values should be separated by commas. |
| !! | Display the ! symbol. |

*Table H-5: Vector-Drawn Positioning and Miscellaneous Commands*

# Formatting Command Examples

The figure below illustrates the relative positions and effects on character size of the level commands. In this figure, the letters "!N" are normal level and size characters.

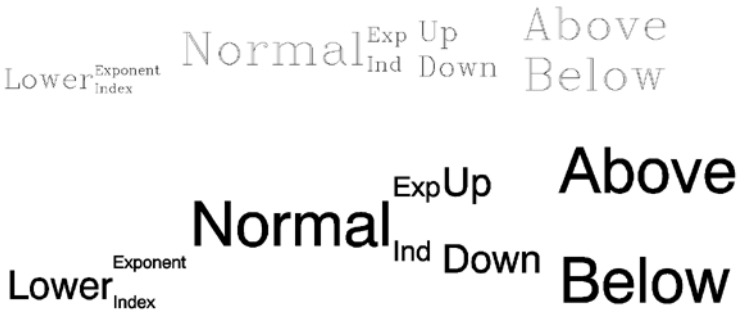


*Figure H-1: Positioning Commands With Vector Fonts (Top) and TrueType Fonts (Bottom)*

The positioning shown was created with the following command:

```
XYOUTS, 0.1, 0.3, $
'!LLower!S!EExponent!R!IIndex!N  Normal!S!EExp!R!IInd!N!S!U Up
!R!D Down!N!S!A Above!R!B Below'
```

Note that the string argument to the XYOUTS procedure must be entered on a single line rather than the two lines shown above.

# A Complex Equation

Embedded positioning commands and the vector font system can be used to create the integral shown below:

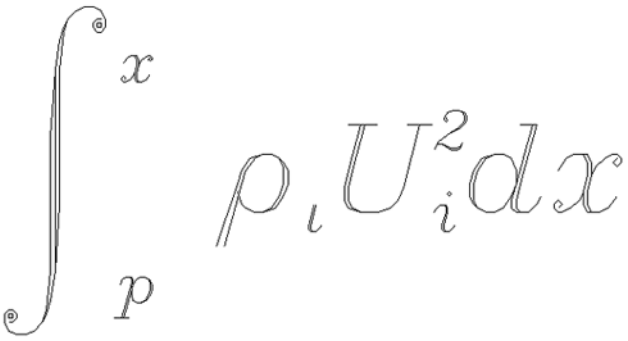

*Figure H-2: An integral created with the vector fonts.*

The command string used to produce the integral is:

```
XYOUTS, 0, .2, $
   '!MI!S!A!E!8x!R!B!Ip!N !7q!Ii!N!8U!S!E2!R!Ii!Ndx', $
   SIZE = 3, /NORMAL
```

Remember that the case of the letter in an embedded command is not important. The string may be broken down into the following components:

### !MI

Changes to the math set and draws the integral sign, uppercase I.

### !S

Saves the current position on the position stack.

### !A!E!8x

Shifts above the division line and to the exponent level, switches to the Complex Italic font (Font 8), and draws the "*x*."

### !R!B!Ip

Restores the position to the position immediately after the integral sign, shifts below the division line to the index level, and draws the "*p*."

### !N !7q

Returns to the normal level, advances one space, shifts to the Complex Greek font (Font 7), and draws the Greek letter rho, which is designated by "*q*" in this set.

### !Ii!N

Shifts to the index level and draws the "*i*" at the index level. Returns to the normal level.

### !8U

Shifts to the Complex Italic font (Font 8) and outputs the upper case "*U*."

### !S!E2

Saves the position and draws the exponent "2."

### !R!Ii

Restores the position and draws the index "*i*."

### !N dx

Returns to the normal level and outputs "dx."

**Note**

The equation shown in the figure above could not be created so simply using the TrueType font system, because the large integral symbol is broken into two or more characters in the TrueType fonts.

## Vector-Drawn Font Example

IDL uses vector-drawn font when the value of the system variable !P.FONT is -1. This is the default condition. Initially, all characters are drawn using the Simplex Roman font (Font 3). When plotting, font changing commands may be embedded in the title strings keyword arguments (XTITLE, YTITLE, and TITLE) to select other fonts. For example, the following statement uses the Complex Roman font (Font 6) for the *x*-axis title:

```
PLOT, X, XTITLE = '!6X Axis Title'
```

This font remains in effect until explicitly changed. The order in which the annotations are drawn is main title, *x*-axis numbers, *x*-axis title, *y*-axis numbers, and *y*-axis title. Strings to be output also may contain embedded information selecting subscripting, superscripting, plus other features that facilitate equation formatting.

The following statements were used to produce the figure below. They serve as an example of a plot using vector-drawn characters and of equation formatting.

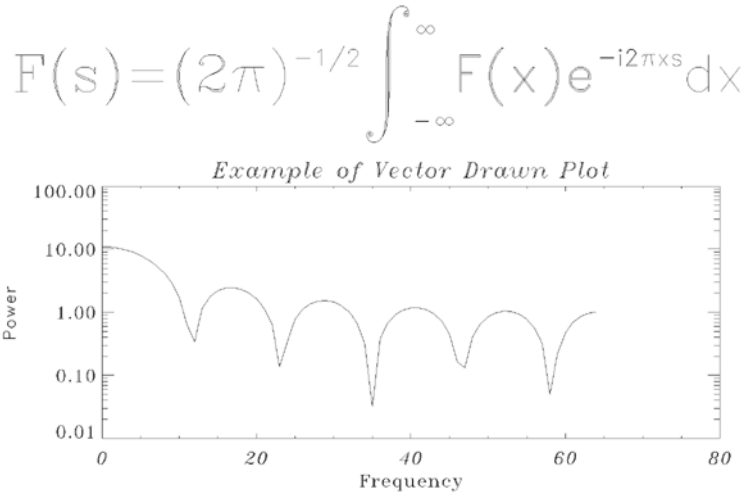

*Figure H-3: Example of a Vector-drawn Plot*

```
; Define an array:
X = FLTARR(128)
; Make a step function:
X[30:40] = 1.0
; Take FFT and magnitude:
X = ABS(FFT(X, 1))
; Produce a log-linear plot. Use the Triplex Roman font for the
; x title (!17), Duplex Roman for the y title (!5), and Triplex
; Italic for the main title (!18). The position keyword is used to
; shrink the plotting window:
PLOT, X[0:64], /YLOG, XTITLE = '!17Frequency', $
   YTITLE = '!5Power', $
   TITLE = '!18Example of Vector Drawn Plot', $
   POSITION = [.2, .2, .9, .6]
SS = '!6F(s) = (2!4p)!e-1/2!n !mi!s!a!e!m $
     !r!b!i ' + '-!m $
```

```
; String to produce equation:
     !nF(x)e !e-i2!4p!3xs!ndx'
XYOUTS, 0.1, .75, SS, SIZE = 3, $
; Output string over plot. The NOCLIP keyword is needed because
; the previous plot caused the clipping region to shrink:
     /NORMAL, /NOCLIP
```

# TrueType Font Samples

The following figures show roman versions of the four TrueType font families included with IDL. The character sets for the bold, italic, and bold italic versions of these fonts are the same as the roman versions.

The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 'Helvetica', 'Helvetica', /TT_FONT
```

For more information, see “SHOWFONT” on page 1788.

**Note**

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the copyright symbol is octal 251.

Font Helvetica

| Octal | 00 | 01 | 02 | 03 | 04 | 05 | 06 | 07 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 |

# Vector Font Samples

The following figures show samples of various vector-drawn fonts. The SHOWFONT command was used to create these figures. For example, to display the following figure on the screen, you would the command:

```
SHOWFONT, 3, 'Simplex Roman'
```

To output this figure to a postscript file, you would use the following commands:

```
SET_PLOT, 'PS'
SHOWFONT, 3, 'Simplex Roman'
DEVICE, /CLOSE
```

For more information, see “SHOWFONT” on page 1788.

**Note**

The following font charts are numbered in octal notation. To read the octal number of a character, add the column index (along the top) to ten times the row index. For example, the capital letter “A” is octal 101, and the “$” symbol is octal 44.

# Appendix I: Obsolete Features

The following topics are covered in this appendix:

# What Are Obsolete Features?

To improve the overall quality and functionality of IDL, Research Systems, Inc. occasionally replaces existing routines with new, improved routines. In many cases, existing routines are improved without changing their existing behavior—through improvements of the underlying algorithms, for example, or by adding keyword functionality. In some cases, however, the improved methods are incompatible with the old. In these situations, we consider the routines that we have replaced to be *obsolete*.

For similar reasons, arguments and keywords to existing routines may occasionally become obsolete. In many cases, the functionality activated by the obsolete argument or keyword can be achieved more efficiently using a new argument or keyword. If this is the case, existing code using the obsolete argument or keyword will generally continue to function as it always has, although performance may be better using the new, replacement argument or keyword. In cases where the obsolete argument or keyword activated functionality that is no longer available (perhaps as a result of an operating system upgrade or change), IDL will either quietly ignore the presence of the argument or keyword (if doing so does not affect the resulting output) or warn that an invalid parameter has been specified.

This chapter lists the routines that have become obsolete in each version of IDL. These routines are not documented in the online help. To view reference information for routines obsoleted in IDL version 5.0 and later, see the `obsolete.pdf` file in the `docs` subdirectory of the IDL distribution. Routines obsoleted in IDL 4.0 and earlier are not documented in the `obsolete.pdf` file. If a `.pro` file for the routine exists, it is located in the `lib/obsolete` subdirectory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the DOC_LIBRARY routine.

# Routines Obsoleted in IDL 6.0

The following routines were present in IDL Version 5.6 but became obsolete in IDL Version 6.0.

**Note**

For information about routines replaced by the iTools system, see the *iTools User's Guide*.

| Routine | Replaced by | .pro File? |
|---|---|---|
| LIVE_CONTOUR | ICONTOUR | |
| LIVE_CONTROL | iTools system | |
| LIVE_DESTROY | iTools system | |
| LIVE_EXPORT | iTools system | |
| LIVE_IMAGE | IIMAGE | |
| LIVE_INFO | iTools system | |
| LIVE_LINE | iTools system | |
| LIVE_LOAD | iTools system | |
| LIVE_OPLOT | IPLOT | |
| LIVE_PLOT | IPLOT | |
| LIVE_PRINT | iTools system | |
| LIVE_RECT | iTools system | |
| LIVE_STYLE | iTools system | |
| LIVE_SURFACE | ISURFACE | |
| LIVE_TEXT | iTools system | |

*Table I-1: Routines Obsoleted in IDL 5.6*

# Routines Obsoleted in IDL 5.6

The following routines were present in IDL Version 5.5 but became obsolete in IDL Version 5.6.

| Routine | Replaced by | .pro File? |
|---|---|---|
| HDF_VD_GETNEXT | HDF_VG_GETNEXT | |
| VAX_FLOAT | VAX_FLOAT keyword to OPEN | |

*Table I-2: Routines Obsoleted in IDL 5.6*

# Routines Obsoleted in IDL 5.5

The following routines were present in IDL Version 5.4 but became obsolete in IDL Version 5.5.

| Routine | Replaced by | .pro File? |
|---|---|---|
| DELETE_SYMBOL | n/a | |
| DELLOG | n/a | |
| DO_APPLE_SCRIPT | n/a | |
| ERRORF | ERF | |
| GET_SYMBOL | n/a | |
| LJLCT | n/a | |
| REWIND | n/a | |
| SET_SYMBOL | n/a | |

| TAPWRT | n/a | |
| TRNLOG | n/a | |
| WEOF | n/a | |

*Table I-3: Routines Obsoleted in IDL 5.5*

# Routines Obsoleted in IDL 5.4

The following routines were present in IDL Version 5.3 but became obsolete in IDL Version 5.4.

| Routine | Replaced by | .pro File? |
|---|---|---|
| POLYFITW | POLY_FIT, MEASURE_ERRORS keyword | `polyfitw.pro` |
| RIEMANN | RADON | |

*Table I-4: Routines Obsoleted in IDL 5.4*

# Routines Obsoleted in IDL 5.3

The following routines were present in IDL Version 5.2 but became obsolete in IDL Version 5.3.

| Routine | Replaced by | .pro File? |
|---|---|---|
| HDF_DFSD_* Routines | HDF_SD_* Routines | |
| RSTRPOS | STRPOS, /REVERSE_SEARCH | `rstrpos.pro` |
| STR_SEP | STRSPLIT for single character delimiters<br>STRSPLIT, /REGEX for longer delimiters | `str_sep.pro` |

*Table I-5: Routines Obsoleted in IDL 5.3*

# SDF Routines Obsoleted in IDL 5.3

HDF_DFSD_* routines have been obsoleted in IDL 5.3.

## What is DFSD and Why Are We Obsoleting It?

DFSD is an SD (Scientific Data Model). DFSD is the older, single-file SD form. The newer SD format, MFSD, is referred to in the IDL API as HDF_SD_*. New IDL code should use HDF_SD_* routines rather than HDF_DFSD_* routines.

Version HDF4.1r2 of HDF has obsoleted the DFSD interface, somewhat forcing us to do so as well. IDL 5.3 uses HDF4.1r3 (Version 4.1, revision 3). It is recommended that users convert their old HDF files to the 4.1r3 format.

The following HDF routines have been obsoleted in IDL 5.3.

- HDF_DFSD_ADDDATA
- HDF_DFSD_DIMGET
- HDF_DFSD_DIMSET
- HDF_DFSD_ENDSLICE
- HDF_DFSD_GETDATA
- HDF_DFSD_GETINFO
- HDF_DFSD_GETSLICE
- HDF_DFSD_PUTSLICE
- HDF_DFSD_READREF
- HDF_DFSD_SETINFO
- HDF_DFSD_STARTSLICE

# Routines Obsoleted in IDL 5.2

The following routines were present in IDL Version 5.1 but became obsolete in IDL Version 5.2.

| Routine | Replaced by | .pro File? |
|---|---|---|
| DEMO_MODE | LMGR | `demo_mode.pro` |

*Table I-6: Routines Obsoleted in IDL 5.2*

# Routines Obsoleted in IDL 5.1

The following routines were present in IDL Version 5.0 but became obsolete in IDL Version 5.1.

| Routine | Replaced by | .pro File? |
|---|---|---|
| SLICER | SLICER3 | `slicer3.pro` |

*Table I-7: Routines Obsoleted in IDL 5.1*

# Routines Obsoleted in IDL 5.0

The following routines were present in IDL Version 4.0 but became obsolete in IDL Version 5.0.

| Routine | Replaced by | .pro File? |
|---|---|---|
| DDE Routines | n/a | |
| GETHELP | OUTPUT keyword to HELP | |
| HANDLE_CREATE | PTR_NEW | |
| HANDLE_FREE | PTR_FREE | |
| HANDLE_INFO | PTR_VALID | |
| HANDLE_MOVE | n/a | |
| HANDLE_VALUE | dereference operator | |
| INP, INPW, OUTP, OUTPW | n/a | |
| PICKFILE | DIALOG_PICKFILE | |
| Old RPC API | New RPC API | |
| .SIZE Executive Command | No longer needed | |
| TIFF_DUMP | n/a | |
| TIFF_READ | READ_TIFF | |
| TIFF_WRITE | WRITE_TIFF | |
| WIDED | n/a | |
| WIDGET_MESSAGE | DIALOG_MESSAGE | |

*Table I-8: Routines Obsoleted in IDL 5.0*

# Routines Obsoleted in IDL 4.0 or Earlier

The following routines became obsolete in IDL version 4.0 or earlier. These routines are not documented in the `obsolete.pdf` file. If a `.pro` file for the routine exists, it is located in the `obsolete` subdirectory of the `lib` directory of the IDL distribution. You can read the documentation header of a routine in the `obsolete` directory either by opening the `.pro` file or using the DOC_LIBRARY routine.

| Routine | Replaced by | .pro File? |
|---|---|---|
| ADDSYSVAR | DEFSYSV | `addsysvar.pro` |
| ADJCT | XPALETTE | `adjct.pro` |
| ANOVA | KW_TEST | `anova.pro` |

# Obsolete Arguments and Keywords

The following arguments and keywords are obsolete and should not be used in new IDL code..

| Routine | Argument or Keyword | Description |
|---|---|---|
| BYTEORDER | DTOGFLOAT keyword | This keyword was available only on the VMS platform |
| | GFLOATTOD keyword | This keyword was available only on the VMS platform. |
| CALL_EXTERNAL | DEFAULT keyword | This keyword was ignored on non-VMS platforms. |
| | PORTABLE keyword | This keyword was ignored on non-VMS platforms. |
| | VAX_FLOAT keyword | This keyword was available only on the VMS platform. |
| DEVICE | DEPTH keyword | This keyword was available only on the VMS platform. |
| | FONT keyword | This keyword was replaced by the SET_FONT keyword. |
| DOC_LIBRARY | FILE keyword | This keyword was ignored on non-VMS platforms. |
| | PATH keyword | This keyword was ignored on non-VMS platforms. |
| | OUTPUTS keyword | This keyword was available only on the VMS platform. |
| EXTRACT_SLICE | CUBIC keyword | EXTRACT_SLICE does not support cubic interpolation. |
| IDLgrMPEG::Save | CREATOR_TYPE keyword | This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms. |

*Table I-10: Arguments and Keywords Obsoleted in IDL 5.5*

| Routine | Argument or Keyword | Description |
|---|---|---|
| LINKIMAGE | DEFAULT keyword | This keyword was ignored on non-VMS platforms. |
| LIVE_PRINT | SETUP keyword | This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms. |
| MAKE_DLL | VAX_FLOAT keyword | This keyword was ignored on non-VMS platforms. |
| ONLINE_HELP | HTML_HELP keyword | This keyword is no longer necessary; ONLINE_HELP parses the value of the BOOK keyword to determine file type. |
| OPEN | *Record_Length* argument | This argument was ignored on non-VMS platforms. |
| | BINARY keyword | Windows file I/O changed to function like UNIX file I/O. |
| | BLOCK keyword | This keyword was ignored on non-VMS platforms. |
| | DEFAULT keyword | This keyword was ignored on non-VMS platforms. |
| | EXTENDSIZE keyword | This keyword was ignored on non-VMS platforms. |
| | FIXED keyword | This keyword was ignored on non-VMS platforms. |
| | FORTRAN keyword | This keyword was ignored on non-VMS platforms. |
| | INITIALSIZE keyword | This keyword was ignored on non-VMS platforms. |
| | KEYED keyword | This keyword was ignored on non-VMS platforms. |

*Table I-10: Arguments and Keywords Obsoleted in IDL 5.5 (Continued)*

| Routine | Argument or Keyword | Description |
|---|---|---|
| OPEN, *continued* | LIST keyword | This keyword was ignored on non-VMS platforms. |
| | MACCREATOR keyword | This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms. |
| | MACTYPE keyword | This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms. |
| | NOAUTOMODE keyword | Windows file I/O changed to function like UNIX file I/O. |
| | NONE keyword | This keyword was ignored on non-VMS platforms. |
| | NOSDTIO | Keyword was renamed RAWIO. |
| | PRINT keyword | This keyword was ignored on non-VMS platforms. |
| | SEGMENTED keyword | This keyword was ignored on non-VMS platforms. |
| | SHARED keyword | This keyword was ignored on non-VMS platforms. |
| | STREAM keyword | This keyword was ignored on non-VMS platforms. |
| | SUBMIT keyword | This keyword was ignored on non-VMS platforms. |
| | SUPERSEDE keyword | This keyword was ignored on non-VMS platforms. |
| | TRUNCATE_ON_CLOSE keyword | This keyword was ignored on non-VMS platforms. |

*Table I-10: Arguments and Keywords Obsoleted in IDL 5.5 (Continued)*

| Routine | Argument or Keyword | Description |
|---|---|---|
| OPEN, *continued* | UDF_BLOCK keyword | This keyword was ignored on non-VMS platforms. |
| | VARIABLE keyword | This keyword was ignored on non-VMS platforms. |
| PRINT/PRINTF | REWRITE keyword | This keyword was ignored on non-VMS platforms. |
| READ_TIFF | ORDER keyword | This keyword was replaced by the ORIENTATION keyword |
| | UNSIGNED keyword | This keyword became obsolete when IDL began supporting an unsigned 16-bit integer data type. |
| READ/READF | KEY_ID keyword | This keyword was ignored on non-VMS platforms. |
| | KEY_MATCH keyword | This keyword was ignored on non-VMS platforms. |
| | KEY_VALUE keyword | This keyword was ignored on non-VMS platforms. |
| READU | KEY_ID keyword | This keyword was ignored on non-VMS platforms. |
| | KEY_MATCH keyword | This keyword was ignored on non-VMS platforms. |
| | KEY_VALUE keyword | This keyword was ignored on non-VMS platforms. |
| SAVE | XDR keyword | IDL always writes XDR files. |

*Table I-10: Arguments and Keywords Obsoleted in IDL 5.5 (Continued)*

| Routine | Argument or Keyword | Description |
|---|---|---|
| SPAWN | FORCE keyword | This keyword was incorrectly included in the SPAWN documentation. |
| | MACCREATOR keyword | This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms. |
| | NOCLISYM keyword | This keyword was ignored on non-VMS platforms. |
| | NOLOGNAM keyword | This keyword was ignored on non-VMS platforms. |
| | NOTIFY keyword | This keyword was ignored on non-VMS platforms. |
| WIDGET_BASE | APP_MBAR keyword | This keyword was ignored on non-Macintosh OS 9 (and earlier) platforms. |
| WRITE_TIFF | *Order* argument | The Order argument has been replaced by the ORIENTATION keyword. Code that uses the Order argument will continue to work as before, but new code should use the ORIENTATION keyword instead. |
| WRITEU | REWRITE keyword | This keyword was ignored on non-VMS platforms. |

*Table I-10: Arguments and Keywords Obsoleted in IDL 5.5 (Continued)*

# Obsolete System Variables

The following IDL system variables became obsolete in the change from VAX IDL (IDL version 1) to IDL version 2. While it is highly unlikely that you will find references to these system variables in existing code, we include them here because they are flagged when the OBS_SYSVARS field of the !WARN structure is set equal to one. See Appendix D, “System Variables” for information on IDL system variables.

| System Variable | Replaced by |
|---|---|
| !BCOLOR | BOTTOM keyword to SURFACE |
| !COLOR | !P.COLOR |
| !CXMAX | !X.CRANGE[1] |
| !CXMIN | !X.CRANGE[0] |
| !CYMAX | !Y.CRANGE[1] |
| !CYMIN | !Y.CRANGE[0] |
| !FANCY | No direct equivalent. Use !P.FONT and !P.CHARSIZE |
| !FLIP | No equivalent. |
| !GRID | !P.TICKLEN |
| !HI | No equivalent. |
| !IGNORE | !P.NOCLIP |
| !LINETYPE | !P.LINESTYLE |
| !LO | No equivalent. |
| !MTITLE | !P.TITLE |
| !NOERAS | !P.NOERASE |
| !NORMALCONT | FOLLOW keyword to CONTOUR |
| !NSUM | !P.NSUM |

*Table I-11: Obsolete System Variables*

| System Variable | Replaced by |
|---|---|
| !PSYM | !P.PSYM |
| !SC1 | !P.POSITION[0] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[0] * !D.X_VSIZE otherwise. |
| !SC2 | !P.POSITION[2] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !X.WINDOW[1] * !D.X_VSIZE otherwise. |
| !SC3 | !P.POSITION[1] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[0] * !D.X_VSIZE otherwise. |
| !SC4 | !P.POSITION[3] * !D.X_VSIZE if !P.POSITION[2] is nonzero, or !Y.WINDOW[1] * !D.X_VSIZE otherwise. |
| !TERM | DEVICE procedure. |
| !TYPE | !X.TYPE, !X.STYLE, !Y.TYPE, !Y.STYLE, !P.TICKLEN |
| !XMAX | !X.RANGE[1] |
| !XMIN | !X.RANGE[0] |
| !XTICKS | !X.TICKS |
| !XTITLE | !X.TITLE |
| !YMAX | !Y.RANGE[1] |
| !YMIN | !Y.RANGE[0] |
| !YTICKS | !Y.TICKS |
| !YTITLE | !Y.TITLE |

*Table I-11: Obsolete System Variables (Continued)*

# Obsolete Graphics Devices

The following arguments and keywords are obsolete and should not be used in new IDL code..

| Graphics Device | Description |
|---|---|
| The LJ Device (LJ) | The LJ device was only available in IDL for VMS. |
| The Macintosh Device (MAC) | The MAC device was only available in IDL for Macintosh versions running under OS 9 and earlier. Versions of IDL for Macintosh running under OS X and later use the X device. |

*Table I-12: Obsolete Graphics Devices*
